The world's output of camphor increased from 7,000,000 to 10,000,000 lb. during the first decade of the century, and in 1916 reached a record of over 17,000,000 lb., declining, however, to 10,000,000 lb. in 1918. The bulk of the world's supply has been from Formosa, which in 1917 exported nearly 10,500,000 lb., but since then the annual falling off in shipments of Formosan camphor has received very serious consideration in England, and new sources of supply are being sought within the British Empire. In 1921, less than 1,000,000 kin of camphor was exported from Formosa, of which Japan received by far the largest quantity. Synthetic camphor as a commercial product has attracted considerable attention of late years, and not only Germany, which has been manufacturing it on a profitable basis for some time, but Japan and America are now engaged in the industry. China is now an important source of supply of camphor, and there are large untouched areas of camphor trees in the Provinces of Kwangsi, Kiangsi, Kwangtung and Yunnan, and the island of Hainan. Exports of camphor from China totalled nearly 2,250,000 lb. in 1921, but in 1922 decreased to 1,500,000 lb., doubtless owing to disturbed conditions in South China.

REVIEWS

LUNGE AND KEANE'S TECHNICAL METHODS OF CHEMICAL ANALYSIS. Edited by C. A. KEANE and P. C. L. THORNE. Volume I. Second Edition. Pp. xx+704. London: Gurney and Jackson, 1924. Price 63s. net.

All chemists concerned with technical analysis are sure to welcome the second edition of this standard treatise, the first volume of which has now left the press. Whereas Volume I of the first edition was issued in two separate parts, the text-matter of the new edition has been slightly re-arranged, and the volumes will be simply numbered One to Six, a simplification which will appeal to all users. The book under review contains the text-matter of the former Volume I up to and including Cyanogen Compounds, but excluding Potassium Salts, which will be treated in Volume II. Two new sections have been added, the one on Electrolytic Methods, by Dr. H. J. S. Sand, the other on Physical Measurements in Technical Analysis, by Dr. J. S. G. Thomas. The remainder of the old Volume I will make up the future Volume II. With the exception of Dr. Keane (who again treats of General Methods of Technical Analysis and Gas Analysis), the contributors to the present work do not include any of the original authors. Mr. G. Nevill Huntly has revised the section on Fuel Analysis, Dr. J. T. Dunn those on Sulphuric, Nitric, and Hydrochloric Acids, Sodium Carbonate, and the Chlorine Industry, whilst Mr. H. E. Williams is responsible for the article on Cyanogen Compounds.

To review the whole of this authoritative treatise within the brief space allotted to the writer is naturally impossible. It is likewise unnecessary to say that the fame of the first English edition, like that of the German original, has long since been firmly established; the names of the present editors and their collaborators convey an assurance that the book will fully maintain its reputation for general excellence and comprehensiveness.

In the chapter dealing with the analysis of pyrites, the writer would have expected to find a reference to the newer methods for the volumetric estimation of arsenic, though, of course, the arsenic assay in ores will be treated more exhaustively in Volume II. Most of the methods described advocate precipitation of the arsenic as silver arsenate, which is either weighed or titrated. The following considerations induced the writer some years since to abandon this form of estimation. When a mineral mixture is fused with alkaline oxidising fluxes, almost any acid-forming element present may find its way into the aqueous extract of the melt. Further, the property of forming an insoluble silver salt is shared by a large number of acids. Unless, therefore, interfering elements are known to be absent (and this premises a qualitative analysis), the silver arsenate may be more or less impure and the results correspondingly high, whether the precipitate is weighed or the silver contained therein titrated after Volhard. Also, silver phosphate and arsenate are known to occlude small quantities of silver nitrates which cannot be removed by washing. A reliable arsenic

estimation should be based on a specific arsenic reaction, such as precipitation of the sulphide in strongly acid solution or the reduction of arsenic acid by iodide and hydrochloric acid. If this is not done, it is hardly surprising that the various methods should "unfortunately lead to widely differing results" (p. 376). The writer remembers an important reference assay in which he found an arsenic content of 0·39 per cent. against 0·57 per cent. by Pearce's method; the latter figure almost duplicated the disputed result. In the reviewer's opinion, the efforts of technical chemists should be directed towards the abandonment of Pearce's method.

A minor question of English terminology arises in the simultaneous use of the two expressions "iodometric" (pp. 51, 602) and "iodimetric" (pp. 65, 67). The former is used in German, whilst the latter appears to be the commoner English term.

W. R. Schoeller.

Fats: Natural and Synthetic. By W. W. Myddleton and T. H. Barry. Pp. xi+182. London: E. Benn, Ltd., 1924. Price, 25s. net.

A publisher once remarked to the reviewer that he regarded the preface of a book as of as much importance from his point of view as the book itself. The reviewer, he cynically remarked, always goes to the preface for his information and frequently does not get any further. Although a preface is seldom so useful as this, it is frequently of some help to the reviewer, for it generally indicates the scope of the book. In this instance the preface suggests that the book is intended for students, and it is from this standpoint, therefore, that it should be mainly considered.

This rather tends to disarm the criticism that the title seems to promise more than the book supplies, and that, in the main, it gives an account of the work of other chemists rather than the development of theoretical knowledge based on the authors' original work.

Much of the book is occupied with summaries of hydrogenation processes and accounts of hydrogenated fats, whilst only five pages are given to the true synthetic fats. This is to be regretted, for, whereas hydrogenated oils are dealt with in several excellent books, there is room for one giving an outline of the various methods of synthesising fats from glycerol and fatty acids.

The subject matter is divided into twelve chapters, which include a brief account of the nature of oils and fats, a somewhat detailed description of the methods of examining fatty acids, a useful and up-to-date summary of processes of extraction, a section on fat-splitting, and an account of the development of catalytic methods of hydrogenation, in which the differences between the ordinary processes and that of the Technical Research Works are clearly shown. This, by the way, is interesting to the technologist, but hardly suitable for students. The physical and chemical examination of hydrogenated fats is dealt with at some length, and results obtained by the authors are described. Then come three chapters on the uses of hydrogenated fats, including one on soaps, which is the best in the book; and finally there is the too brief account of true synthetic fats.

Much valuable information has been brought together in an attractive setting, and it is useful to have it in a form convenient for reference. Regarded as a whole, however, the work strikes one as somewhat disjointed, and the facts as presented will not be readily assimilated, especially by students.

C. Ainsworth Mitchell.

The Modern Soap and Detergent Industry including Glycerol Manufacture. By G. Martin, D.Sc., Ph.D. Vol. I. Theory and Practice of Soap Making. Pp. xii+384. London: Crosby Lockwood and Son, 1924. Price 36s.

This volume deals with the raw materials, both organic and inorganic, used in the soap industries, together with soap-boiling and the manufacture of household and laundry soaps. It includes also a section dealing with the essential oils used in the soap trade and also one dealing with the nature of soap and detergent action.

The arrangement of the sections is useful and convenient. The section which deals with the nature of soap and detergent action is to be noted for its very complete list of references to the literature dealing with the constitution and physical properties of soaps. This list is very extensive and covers the whole field of soap research from a theoretical point of view. It is evident that in this section the author is on his most familiar ground and if later sections dealing with the practical side of the soap industry had been written with the same amount of knowledge the book would be a most useful one. As it is, however, the practical section of the book is inferior to the theoretical and appears to have been compiled by the abstraction of various books and literature of a "practical" nature rather than to have been written by one who has had an extensive practical experience of soap-making under modern conditions. The practical sections are thus a curiously uneven mixture of modern processes and machinery and out of date or impractical methods of working. This would render it somewhat difficult for an inexperienced person to obtain a sound basis of practical knowledge from the sections of the book devoted to soap manufacture. On the whole, however, the book is one which can be read with interest.

F. G. Reynolds.

Chemical Encyclopædia. By C. T. Kingzett. Third edition, revised and enlarged. Pp. x+606. London: Baillière, Tindall and Cox, 1924. Price 30s.

The call for a third edition of this work of reference in the few years since its publication and its enlargement from 539 to 606 pages, as well as the provision of a larger page and better paper, show that it fills a need. Improvements have been made in each edition and much new information is now provided. Accuracy has been consistently sought for, and it is for this reason that the title of the work has been changed from that of the "Popular Chemical

Dictionary" to the present one. A wide range is covered, including minerals, proprietary products, apparatus, theoretical definitions, as well as chemicals of many kinds. It is evident that there is a public demand for information on the many chemical materials and subjects that are becoming more and more a feature of every-day life, and such information is supplied in abundance by the "Chemical Encyclopædia." The book is well presented in every way.

Aide-Mémoire pour L'Industrie du Caoutchouc et des Matières Plastiques. *By* A.-D. Luttringer. Pp. 225. Paris: A.-D. Cillard, 1923.

This book is designed to serve as a compendium of useful information for the rubber and allied industries, and the author states that it is the first of a series of monographs relating to various branches of these industries, which are to be published in conjunction with specialists.

The first chapter is a collection of mathematical tables, weights and measures, conversion tables and physical constants, whilst Chapter II consists of tables of formulæ and physical properties of inorganic and organic compounds. These tables cover the first 100 pages, and contain little information that cannot be found in the *Chemists' Year Book, Bayley's Chemists' Pocket Book*, or any similar work.

Chapter III is a useful dictionary of technical products and terms and trade names, though certain deficiencies may be pointed out. A number of the accelerator trade names, with which the list is replete, is qualified simply by the word "accelerator," and some notable omissions are "Catalpo," "Excellerex" and "Titanium White."

Chapter IV contains a miscellaneous collection of data referring to latex, raw rubber and fillers, and of these the table of densities of compounding ingredients, reprinted from Tuttle's "Analysis of Rubber," is probably the most useful. Its utility would, however, have been greatly enhanced if other physical properties such as refractive index and size of particle were included where possible. Again certain omissions are noted, *e.g.*, "Timonox" and "Titanium White."

Chapter V is devoted to the mechanical testing of rubber and fabrics, and deals almost exclusively with the Breuil dynamometer and elasto-durometer, whilst Chapter VI, on the chemical analysis of rubber and the principal compounding ingredients, is taken from the standard works of Pontio, Caspari and Tuttle.

A brief chapter follows containing statistics of rubber production and distribution, with a concluding chapter on the analysis and testing of a variety of plastic materials including cotton, camphor, nitrocellulose, celluloid, cellulose acetate and photographic films.

The author succeeds in presenting a large amount of material in a condensed form, though most of the useful matter is to be found in other books which are probably available to all who may be interested in the subject.

R. N. Johnson

Handbuch der biologischen Arbeitsmethoden. Lieferung 117: Die Blattfarbstoffe. By Richard Willstätter. Pp. 70. Berlin: Urban und Schwarzenberg. Price 3.40 Swiss francs.

Any volume on plant pigments with which the name of Prof. R. Willstätter is associated is certain to be worthy of the closest attention, for the isolation and investigation of chlorophyll and the carotinoid pigments, carotin and xanthophyll, are very largely due to the remarkable series of investigations which he and his collaborators have carried out. The main results of these extended researches have already been published in two volumes ("Untersuchungen über Chlorophyll" and "Untersuchungen über die Assimilation der Kohlensäure," R. Willstätter and A. Stoll), in which the whole subject is given the very fullest treatment both from the theoretical and experimental points of view. The present volume, which consists of a most lucidly constructed *précis* of these, will undoubtedly be of the greatest value to all workers in the border-line field of botany and chemistry. Full details of the process employed for the extraction and separation of the leaf pigments from one another are given, as also the methods adopted for the quantitative estimation of each. The question of the so-called crystalline chlorophyll is discussed, and exact details for the preparation of both ethyl and methyl chlorophyllid fully described. In addition, the isolation of a number of the more important chlorophyll decomposition products, such as phæophytin, phytochlorin "e," phytorhodin "g" and the unsaturated alcohol, phytol, are dealt with in such a manner as to render their preparation easy to the careful manipulator.

Although, as already stated, there is nothing essentially new in the present volume, the clear and concise manner in which an undoubtedly difficult subject is handled is bound to ensure its welcome reception by all active workers in this field of chemistry.

I. M. Heilbron

Organische Chemie. By Prof. R. Pummerer. Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, edited by Dr. E. Liesegang. Vol. III. Second Edition, revised and enlarged. Pp. xii+210. Dresden and Leipzig: Theodor Steinkopff, 1923. Price, paper, 4s.

The first edition of this useful summary of the outstanding researches published since 1914 covered the work done up to the end of 1920 (*cf. J.*, 1922, 165 R.). In the new edition the treatment of the various subjects is brought up to date by the inclusion of work done in 1921 and 1922. There is every sign of a thorough revision: new paragraphs and footnotes have been added and others rewritten; the subject index has been condensed, but shows about 5 per cent. of new references, and the name index has grown by nearly one-half, the whole book showing an increase of 27 pages. The interest of the discussion is well maintained, and the revision has added to the value of the book for advanced workers in organic chemistry.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Safeguarding of Industries Act

In a written reply addressed to Mr. A. Williams. Mr. Snowden stated that the net revenue collected from the duties imposed under the Safeguarding of Industries Act, 1921, during each of the financial years 1921-22, 1922-23, 1923-24 was: £140,299, £567,097, and £587,000 respectively. For 1922-23 and 1923-24 the figures given relate to Great Britain and Northern Ireland only. The net amounts of duty collected in Great Britain and Northern Ireland to March 31, 1924, under the orders made under Part II. of the Safeguarding of Industries Act, are as follows: Under the Safeguarding of Industries (No. 1) Order, 1922, of August 8, 1922—£429,001; under the Safeguarding of Industries (No. 2) Order, 1922, of October 9, 1922—£50,436, the total being £479,437.—(Apr. 15.)

Soda Concession, Kenya

In a written answer, Mr. Thomas informed Mr. Ormsby-Gore that a scheme for the reconstruction of the Magadi Soda Co. was prepared during 1923, approved by the liquidator, and the Kenya Government, and circulated to the shareholders in January last. Messrs. Brunner Mond then came forward with an alternative scheme which the liquidator and the Kenya Government were prepared to accept, but after careful consideration it was decided that the first scheme should stand, as it offered better prospects of maximum production from Lake Magadi. In view of the recent order for compulsory liquidation negotiations on the whole question had been reopened.—(Apr. 29).

Nauru Phosphates

Replying to various enquiries, Mr. Thomas stated that the output of phosphate from Nauru and Ocean Island was 1,253,280 tons, distributed as follows:—United Kingdom, 32,300 t.; Australia, 794,570 t.; New Zealand, 126,800 t.; and to other countries, 299,610 t. The last shipment to the United Kingdom was made on November 11, 1921, the main factor in determining the amount shipped being the price. The f.o.b. price of Nauru and Ocean Island phosphate was now probably about 15s. a ton below that at which the last cargo was shipped to the United Kingdom. The present approximate c.i.f. price in the United Kingdom was about 42s. below that of the last shipment, which was 3s. above the pre-war price. The amount of interest on capital and sinking fund charges paid annually by the Nauru and Ocean Island undertakings to the owning Governments was £224,053, representing, up to December 31, 1923, a charge of about 12s. 6d. per ton. No guarantee could be given with regard to future readjustments between the three Governments concerned under Article 14 of the Nauru Island Agreement.—(May 5)

Dr. R. C. Wallace, professor of geology in the University of Manitoba, has been elected president of the Canadian Institute of Mining and Metallurgy.

COMPANY NEWS

CASTNER-KELLNER ALKALI CO., LTD.

It is proposed to distribute an interim dividend of 8 per cent. (actual) for the six months ended March 31. The same dividend was distributed last year.

BRUNNER, MOND & CO., LTD.

A dividend on the ordinary shares for the half-year ended March 31 is to be paid of 14 per cent. per annum, making 10½ per cent. for the whole year, less tax (against 11 per cent. in the previous year). A sum of £150,000 (£225,000) has been carried to suspense account, £88,000 (£62,215) to general reserve, and £86,000 (£91,911) is carried forward.

BRITISH CYANIDES CO., LTD.

The directors of the British Cyanides Company have issued a statement regarding the present position of the company. It is stated that since the last circular was issued, in December last, prices have fallen still further. At the same time, the fertiliser trade in America has suffered a complete upheaval, with the result that that source of income is temporarily suspended.

As a consequence of these trade conditions, the company has for the past few months been working at a loss, the standing charges being too heavy. The first unit of plant for the fixation of atmospheric nitrogen disclosed certain defects in course of working, and in the meantime a second unit had been erected. Both have now been closed down and a new furnace is being erected.

Recently an order has been made by the Court, on the petition of the Government, for the liquidation of the British Potash Co. It is not known at present what sum will be realised for the assets, and it will be necessary to deal with this position in the company's balance-sheet.

Sir Arthur Duckham has resigned from the board.

During the past few months a new chemical product for use in the motor tyre and other rubber industries has been manufactured at the works, and profitable business is anticipated.

ASSOCIATED PORTLAND CEMENT MANUFACTURERS, LTD.

The report states that although the demand for Portland cement in 1923 improved in the home and export markets, lower prices were realised. The company's export trade, which represented nearly 40 per cent. of its aggregate deliveries, was carried on at little or no profit, owing to the severe competition of Continental manufacturers, helped by the depreciation of their respective currencies. These factors resulted in a reduction of the profits earned, which at £582,328, including revenue from investments, compare with £675,396 in 1922. These results are obtained after setting aside the sum required to meet the estimated liability for taxation. After making provision for the interest and sinking funds on the Debenture Stock Issues, and for the

dividend for the year on the Preference shares, and after placing £125,000 to general depreciation reserve together with £15,000 to barge depreciation, there remains no balance available for the payment of a dividend on the Ordinary shares without encroaching on the balance brought forward from the previous year, which is not considered advisable in view of the general conditions of trade.

REPORT

Report on the Economic and Financial Conditions in Belgium and Luxemburg, December, 1923. By J. Picton Bagge, Commercial Secretary, Brussels. Department of Overseas Trade. Pp. 112. H.M. Stationery Office, 1924. Price 3s.

The improvement in the industrial activity of Belgium which became noticeable in 1922 was continued in 1923 (*cf. Chem. and Ind.*, 1923, 545), though it is generally recognised that with a return to normal exchange conditions the period of prosperity must cease.

In the first nine months of 1923 imports into Belgium (including Luxemburg) were valued at 9016 million francs, and exports at 6099 million fr. The country has large metallurgical industries, and as a result of the recent stoppage of German supplies attention has been drawn to the need of producing blast-furnace coke at home. The Campine coal basin, which furnishes a suitable coal, has therefore been developed, and in 1923 about 800,000 tons were obtained from this source. In general, coal production in the country made good progress in 1923, and the average monthly production is now about the same as before the war, 1,900,000 t. The metallurgical industries had a fairly good year. The average number of blast furnaces in operation was 37, with a total monthly output of 150,000 t. each of pig-iron and crude steel. The zinc industry has been very active and in the first nine months of 1923 57,000 t. of unrefined metal was exported; sheet zinc valued at 103 million fr., and zinc oxide valued at 40 mill. fr., were also exported in the same period. Imports included 418,244 t. of zinc ore, 22,084 t. of copper ore, 123,836 t. of manganese ore, and 24,118 t. of lead ore. Great Britain supplied only a small proportion of the metals imported.

Textiles enjoyed a prosperous year, the activity in the silk industry being phenomenal. The glass industry has also been prosperous, exports in the first ten months of 1923 being 50,900 t. The situation in the chemical industry is good. The demand for sulphuric acid has been greater than production, though hydrochloric acid has been over-produced. Superphosphates and Thomas slag were in demand in the spring, but stocks have been accumulating for this year. The soap industry has been prosperous in spite of strong competition at one period. Cement was in demand throughout the year for reconstruction purposes, and, later in the year, for export to Japan. The production of 275,000 t. of sugar estimated for the year will leave a good margin for export after after home demands have been met.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5⅜d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid.
Sod. Bichromate.. ..	4¼d. per lb.
Sod. Bisulphite Powder 60/62%..	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5⅜d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide ..	3s. 9d. per lb.

Carbon Bisulphide .. £24—£26 per ton according to quantity.
Carbon Black .. .. 6¼d.—6¾d. per lb. Market firmer. There is a possibility of legislation to control the amount of natural gas used in production of American black. This may mean higher prices, and manufacturers are not anxious to accept orders.
Carbon Tetrachloride .. £56 per ton, drums free.
Chromium Oxide, green .. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark: 4¾d.—6¼d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. 43s. 6d. per cwt., barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Chloride .. 3d. per lb., carboys extra.
Thiocarbanilide .. .. 2s. 9d. per lb.
Vermilion, pale or deep .. 5s. 1d. per lb. Much dearer, following rise in quicksilver.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—
Brown .. .. .. £14 10s. per ton d/d. Demand active.
Grey .. .. .. £19—£20 per ton.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. „ „ 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 6s.—5s. 3d. per gall. 60% O.P. market stiffer.
Solvent .. .. 5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar .. .. £5 per ton.
Brown Sugar of Lead .. £49 per ton.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 7½d. per lb. Only limited inquiry.
Crude 60's .. .. 1s. 10d.—2s. per gall. Market rather flat.
Acid Cresylic, 97/99 .. 1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95% .. .. 1s. 10d.—2s. per gall. Steady demand.
Dark .. .. .. 1s. 7d.—1s. 10d. per gall. Steady business.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 10d.—11d. per gall. Very quiet.
Unstrained .. .. 8½d.—9d. per gall.
Benzole—
Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.
Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 10d.—1s. 11d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 9¾d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification: 7½d.—9d. per gall. according to grade and district. Market a shade firmer. Fair business.
Naphtha—
Crude .. .. .. 8d.—9d. per gall.
Solvent 90/160 .. 1s. 5d.—1s. 7d.
Solvent 90/190 .. 1s. 2d.—1s. 3d.
(Better demand. Prices firm.)
*Naphthalene Crude—
Drained Creosote Salts £6—£7 10s. Demand not so good.
Whizzed or hot pressed £9—£12 per ton. Not much inquiry.
Naphthalene—
Crystals and Flaked .. £17—£18 per ton.
Pitch, medium soft .. 52s. 6d.—57s. 6d. per ton. Market steadier. Few inquiries for forward delivery.
Pyridine—90/140 .. 22s.—24s. per gall. Demand well maintained.
Heavy .. 11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 3d. per lb. Steady demand.
Acid Sulphanilic .. 10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4¾d.—5½d. per lb. Demand moderate.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50°C. 8d.—9d. per lb. naked at works.
66/68°C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 1d. per lb. d/d.
Monochlorbenzol .. .. £63 per ton.
β Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 4½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 4d. per lb. d/d.
Nitrobenzene .. .. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. 11¾d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 2d. per lb. d/d.

p-Phenylene Diamine	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£49 per ton.
Acid, Acetyl Salicylic	3s. 4d.—3s. 6d. per lb. Steady.
Acid, Benzoic B.P.	3s. 3d.—4s. per lb. Larger supplies available.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	Prices quoted from 2s. 2d. per lb. down to 1s. 9d. for ton lots. Market rather quiet.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Very dull market.
Amidopyrin	13s. 6d. per lb. Neglected.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market firm. Continental prices advancing.
Potassium	9d.—10½d. per lb.
Sodium	9d.—10½d. „
Ammonium	10½d.—1s. „
Calcium Lactate	Demand not very active. Good English make can be had from 1s. 7d. to 2s. per lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	11s. 6d. per lb. for cwt. lots. Supplies not plentiful.
Hexamine	3s. 9d. per lb. for foreign makes. Without much inquiry. Large stocks.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 9d. per lb. Foreign make.
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	70s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Market rather flat, but prices unchanged.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. „
White precip.	4s. 7d.—4s. 8d. „
Calomel	3s. 11d.—4s. „
Methyl Salicylate	2s. 3d.—2s. 9d. per lb. for carboys. A slightly better market.
Methyl Sulphonal	24s. per lb. neglected.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin	6s. 3d.—6s. 6d. per lb. Shows slight improvement.
Phenazone	7s. 6d. per lb. for cwt. lots.
Phenolphthalein	6s. 9d.—7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal	8¾d.—9d. per lb. carriage paid. English make.
Commercial	8d.—8½d. per lb. carriage paid. English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Salol	4s. per lb. Very quiet.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	3s.—3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite— Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet
Sod. Salicylate	Market improved with good deal of inquiry. Powder 2s. 4d.—2s. 6d. per lb. Crystal at 2s. 6d.—2s. 8d. per lb. Flake 2s. 9d.—3s. 4d. per lb.

Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	.. 16s.—18s. per
Tartar Emetic ..	.. 1s. 4d. per lb.
Thymol	.. 13s. 6d.—15s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.
Aubepine	.. 13s. 6d. ,,
Amyl Acetate ..	.. 2s. 9d. ,,
Amyl Butyrate ..	.. 7s. 3d. ,,
Amyl Salicylate ..	.. 3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d. ,,
Benzaldehyde free from Chlorine ..	.. 3s. 6d. ,,
Benzyl Benzoate	.. 3s. 6d. ,,

Palma Rosa Oil ..	.. 19s. per lb. Very short supply.
Peppermint Oil—	
Wayne County	.. 21s. 9d. per lb.
Japanese ..	.. 19s. 3d. per lb.
Petitgrain Oil ..	.. 10s. per lb.
Sandal Wood Oil—	
Mysore	.. 26s. 6d. per lb.
Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before June 30th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—Applications

Aktiebolaget Separator. Preventing injurious reaction between centrifugated liquid and air. 10,094. Apr. 23. (Swed., 2.8.23.)

Avamore Engineering Co., Ltd., and Hetherington. Apparatus for mixing and thermal treatment of materials. 10,102. Apr. 23.

Denham, and Simon, Ltd. Apparatus for giving warning of escape etc. of gases. 9906. Apr. 22.

Edelstahlwerk Rochling Akt.-Ges., and Ziegler. Regenerative furnaces. 10,290. Apr. 25. (Ger., 12.7.23.)

Griscom-Russell Co. Evaporators. 10,005. Apr. 22. (U.S., 26.6.23.)

Jackson. (Royer Foundry and Machine Co.). Treating granular material. 10,128. Apr. 23.

Schloss (Rowe). Beaters for grinding-mills etc. 10,099 Apr. 23.

I.—Complete Specifications Accepted

941 (1923). Hurrell. Mixing, incorporating, and disintegrating machines. (214,308.)

2063 (1923). Cowles. Solidifying materials that solidify with a rise in temperature. (214,344.)

9725 (1923). Veitch. Mixing apparatus. (214,446.)

19,142 (1923). Carter, May, and Barradell. Film-mills for emulsifying and grinding solids. (214,521.)

II.—Applications

British Thomson-Houston Co., Ltd. Filaments. 10,311 Apr. 25. (U.S., 1.5.23.)

Duckham, and Woodall-Duckham, Ltd. Operating vertical retorts for carbonizing fuel. 10,313 and 10,364. Apr. 25 and 26.

Ledoga Soc. Anon., and Maimeri. 10,105. *See* XX.

Pyzel. Fractional distillation of oils etc. 9993. Apr. 22.

Pyzel. Fractioning oil vapours. 9994. Apr. 22.

II.—Complete Specification Accepted

23,232 (1923). Johnson (Badische Anilin und Soda Fabrik). Manufacture of fuel gas. (214,544.)

III.—Application

Pyzel. 9993-4. *See* II.

IV.—Applications

Ransford (Cassella & Co.). Dichlor-N-dihydro-1.2-2′1′-anthraquinoneazine. 10,000. Apr. 22.

Soc. Alsacienne de Produits Chimiques. Manufacture of sulphurized compounds of phenol etc. 10,366. Apr. 26. (Fr., 27.4.23.)

Soc. of Chemical Industry in Basle. Manufacture of arylidoquinones. 10,212. Apr. 24. (Swiss., 24.4.23.)

IV.—Complete Specifications Accepted

34,168 (1922). Tizard, Chapman, and Taylor. Halogenation of hydrocarbons and their derivatives. (214,293.)
6016 (1923). Poma. Manufacture of *p*-aminophenol. (194,694.)
18,008 (1923). Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of corinth-coloured to black azo-dyestuffs. (214,516.)

V.—Complete Specification Accepted

1674 (1923). Clayton Aniline Co., Ltd., and Grundy. Treatment of acetyl cellulose in alkaline liquids. (214,330.)

VI.—Applications

Ashworth. Apparatus for dyeing etc. yarns in hanks. 9891. Apr. 22.
Hunt, and Hunt and Moscrop, Ltd. Open bleaching, dyeing, etc. machines. 10,061. Apr. 23.
Scottish Dyes, Ltd., Thomas, and Thomson. Dyeing processes. 10,176. Apr. 24.

VI.—Complete Specifications Accepted

2866 (1923). Stevens and Dyer. Treating fabrics with rubber compositions. (214,356.)
17,229 (1923). Scholz. Producing batik discharge patterns. (214,506.)
32,113 (1923). Hamburger and Kaosz. Bleaching vegetable fibrous material. (209,073.)

VII. Applications

Denham, and Simon, Ltd. Means for detecting etc. chlorine etc. 9908. Apr. 22.
Dubois. Production of hydrocyanic acid. 10,100. Apr. 23.
Dubois. Production of hydrocyanic acid. 10,101. Apr. 23. (Ger., 23.4.23.)
Elektro-Osmose Akt.-Ges. (Graf Schwerin Ges.). Manufacture of amorphous silicic acid. 10,365. Apr. 26. (Ger., 26.4.23.)
Imray. 10,022. *See* X.

VII.—Complete Specifications Accepted

1774 (1923). Bhopal Produce Trust. Recovery of calcium oxalate and other materials from trees. (201,131.)
2914 (1923). Naef. Production of compounds of sulphur with alkali or alkaline earth metals. (214,358.)
14,283 (1923). Chem. Werke vorm. Auerges., Sommer, and Ans. Production of titanic oxide from titaniferous iron ores. (214,483.)
14,663 (1923). Rhenania Verein Chem. Fabr. Production of soluble salts of barium and strontium from the residues of the manufacture of barium and strontium sulphides. (201,528.)
14,936 (1923). Urfer. Preparation of pulverised lithium nitride. (199,027.)

VIII.—Application

Battiscombe. Apparatus for drying china clay etc. 9884. Apr. 22.

IX.—Complete Specification Accepted

6386 (1923). Hatton. Manufacture of coloured tiles, slabs, bricks, etc. (214,394.)

X.—Applications

British Thomson-Houston Co., Ltd. Tungsten alloys. 10,187. Apr. 24. (U.S., 1.5.23.)
Electrolytic Zinc Co. of Australasia, Ltd. Recovery of zinc by electrolysis. 9947. Apr. 22. (Australia, 21.4.23.)
Flodin and Gustafsson. Methods of producing volatile metals from their sulphides. 10,152. Apr. 24. (Sweden, 25.4.23.)
Flodin and Nobel. Method for producing metals and metal alloys low in carbon. 9883. Apr. 22. (Sweden, 20.4.23.)
General Electric Co., Ltd. Manufacture of tungsten wires. 9979. Apr. 22. (Hungary, 21.4.23.)
Imray (Bellis Heat Treating Co.). Fused eutectic salt baths. 10,022. Apr. 22.
Talbot. Metallurgical furnaces. 10,210. Apr. 24.
Wittig. Method of producing metallic vanadium. 10,357. Apr. 26. (Ger., 7.5.23.)

X.—Complete Specifications Accepted

1975 (1923). Cleave. Apparatus for the electrolytic deposition of metals. (214,340.)
1983 (1923). Wandel. Cleaning rusty or corroded iron. (208,103.)
7076 (1923). Sejournet. Manufacture of powders of alloys of magnesium and aluminium. (195,064.)
11,981 (1923). Soc. Anon. des Brevets Berthot. Electrical process for obtaining metals of high melting-point, such as tungsten. (205,046.)
19,772 (1923). Robinson and Gray. Composition for moulds for steel castings. (214,526.)
20,700 (1923). Lombardi. *See* XI.

XI.—Applications

Banyay. Making active material for electric accumulators. 10,134. Apr. 24.
Barfield, Coleman, and Wild. Electric muffle furnaces. 10,174. Apr. 24.
Electrolytic Zinc. Co. of Australasia, Ltd. 9947. *See* X.

XI.—Complete Specifications Accepted

1975 (1923). Cleave. *See* X.
11,981 (1923). Soc. Anon. des Brevets Berthot. *See* X.
20,700 (1923). Lombardi. Electric furnaces, particularly for melting and treatment of composite metals and alloys. (211,532.)

XII.—Application

Naamlooze Vennootschap Koninklijke Stearine Kaarsenfabriek Gouda. Manufacture of soap. 10,205. Apr. 24. (Holl., 30.8.23.)

XII.—Complete Specification Accepted

14,054 (1923). Fauth. Continuous recovery of oils from oilseeds. (214,478.)

XIV.—Complete Specifications Accepted

2866 (1923). Stevens and Dyer. *See* VI.
3058 (1923). Lawes. Rubber composition. (214,361.)
13,750 (1923). Oltmans. Obtaining rubber from latex. (214,477.)

XVI.—Application

Garbin and Toniolo. Phospho-nitrogenous fertiliser. 10,178. Apr. 24.

XVIII.—Complete Specification Accepted

31,846 (1922). Barbet et Fils et Cie. Distillation and rectification of alcohols. (189,458.)

XIX.—Applications

Heyerdahl. Production of edible products rich in vitamines. 10,227, 10,228. Apr. 25.
Smallpeice. Methods of preserving decomposable fluids. 10,041. Apr. 22.

XX.—Applications

Ledoga Soc. Anon., and Mainneri. Preparation of diethyl sulphate from ethylene. 10,105. Apr. 23. (Italy, 23.4.23.)
Swartz. Anaesthetising gases. 10,183. Apr. 24.

XX.—Complete Specifications Accepted

34,168 (1922). Tizard, Chapman, and Taylor. *See* IV.
30,087 (1923). Merck. Preparation of synthetic *d*-ψ- and *l*-ψ-cocaine. (210,050.)

XXIII.—Application

Denham, and Simon, Ltd. 9908. *See* VII.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number :—*Algiers*: Tinplate (492); *Australia*: Pottery, glassware and aluminium ware (470); Aluminium, enamel ware, agricultural and engineers' tools (Official Secretary, Commercial Bureau, Australia House, Strand, London, W.C. 2. Ref. No. 412/7/1/1/236); *British India*: Steel (The Directors of the Madras and Southern Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, London, S.W. 1); *Canada*: Steel, Manganese castings (472); Drugs (476); Mining and engineering equipment (477); *Chile*: Glycerine, oils (494); *Denmark*: Magnesia slabs (481); Copper ingots (482); *Mexico*: Tinplate (495); *Netherlands*: Artificial silk (485); Stationery (486); *Peru*: Tableware, sanitary earthenware (496); *South Africa*: Rubber goods, stationery (478); *Spain*: Silk (490).

French Company News

The St. Etienne coalmines company is constructing 25 new coke ovens, thus bringing the number up to 100. Wishing to utilise the hydrogen produced from distilling coke for the production of synthetic ammonia, and to produce industrial gas of 1300 calories by using fuels of high ash content, arrangements have been made with the Société Chimique de la Grand Paroisse, the owner of the Claude Process, for the construction of a synthetic-ammonia factory capable of producing 5 m.t. per 24 hours. The factory, which will be ready in June, 1924, will in time produce 10 t. per 24 hours. To provide for the utilisation of the industrial gas, the company has made an agreement with the Société Franco-Belge de Fabrication Mécanique du Verre (which makes window-glass by the Libbey-Owens process) to utilise the gas for local glass furnaces. In 1923, the St. Etienne coal mines produced 608,190 tons of coal and 159,130 tons of coke, 3097 tons of tar, 1418 tons of ammonium sulphate, 912 tons of benzol, and varying quantities of other products such as heavy and light oils, naphthalene, anthracene and tar.

The Canadian Market

British manufacturers, particularly those producing mining and chemical machinery, apparatus and plant, will be interested in the recent Canadian budget. The customs tariff has placed on the free list many appliances used in mineral, metallurgical and chemical industries, and especially those not made in the country, or of such size or construction as are not generally manufactured. This will apply to such articles as filter presses, distilling apparatus, evaporators, driers, vacuum apparatus, grinding and dressing machinery, mining drills and many parts, and special machinery for chemical plants. The object of this reduction in the tariff is to encourage and facilitate the development of such industries as low-carbonisation of coal, coke and the recovery of by-products therefrom in the form of fuel, and motor oils, fertiliser, etc., oil shale and tar sands, mining and many industries which have been hampered by the excessive duties and sales tax (remitted) upon articles not made in Canada, or not available of proper construction and design to permit of economic application. The new tariff proposals may be seen at the office of the High Commissioner for Canada.

Trade Information

Midland Bank.—Mr. George McBain and Mr. A. Hall Wilson, Directors of the North of Scotland Bank, Ltd., have been appointed Directors of the Midland Bank, Ltd. The Right Hon. R. McKenna, Chairman of the Midland Bank, and Mr. Frederick Hyde, Joint Managing Director of that Bank, have been appointed Directors of the North of Scotland Bank, Ltd.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during April has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 484, of which 380 were from merchants or importers. To these should be added 22 cases outstanding on April 1, making a total for the month of 506. These were dealt with as follows :—Granted—360 (of which 329 were dealt with within 7 days of receipt). Referred to British makers of similar products—84 (of which 63 were dealt with within 7 days of receipt). Referred to Reparation supplies available—30 (all dealt with within two days of receipt). Outstanding on April 30, 1924—32 (practically the whole of these were dealt with at meeting held May 2. Of the total of 506 applications received, 422 or 83 per cent were dealt with within 7 days of receipt.

PUBLICATIONS RECEIVED

Chemistry in the Twentieth Century. Prepared under the guidance of a Committee representing the Scientific Societies, with Dr. E. F. Armstrong, F.R.S., as Chairman and Editor. Pp. viii+281. London: Ernest Benn, Ltd., 1924. Price 15s.

Chemicals. By A. W. Ashe and H. G. T. Boorman, with a foreword by H.R.H. The Prince of Wales. Resources of the Empire Series. Pp. 207. London: Ernest Benn, Ltd., 1924. Price 21s.

A Dictionary of Applied Chemistry. By Sir E. Thorpe, C.B., LL.D., F.R.S. Assisted by eminent contributors. Revised and enlarged edition. Vol. V. Pp. viii+722. London: Longmans, Green and Co., 1924. Price 60s.

Principles of Electroplating and Electroforming (Electrotyping). By W. Blum and G. B. Hogaboom. Pp. xii+356. London: McGraw-Hill Publishing Co., Ltd., 1924. Price 20s.

Drying by Means of Air and Steam. By E. Hausbrand. Third revised English edition. Pp. viii+77. London: Scott, Greenwood and Son, 1924. Price 6s.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY *&* INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, MAY 16, 1924 No. 20

EDITORIAL

It was neither diffidence nor laziness which prevented us last week from making a final comment on the relations between the French and German chemists. Editors of weekly journals are not expected to be either timid or dilatory; even when they are away on a holiday or stricken by illness, they must exercise their brains, that is, assuming with the sentry, they have got any. Some of the correspondence we received last week arrived so late that there was no time to comment upon it in these columns. This is the round, unvarnished tale we have to deliver. Nor have we been careless in alluding to the relations between the French and German chemists; this is in truth the whole essence of the problem. Various English chemists have written to us that our comments have shown too much hostility towards the Germans, or that we have shown much less hostility than was proper; in such matters a middle course pleases no one, we have shot neither the woodcock nor the pigeon. But the relations between the British and the German chemists are not the crux of the situation; it is the feeling between the French and the Germans which is this. In view of the recent elections in both countries, the possibilities of satisfactory arrangements about indemnities, the pourparlers now proceeding in Europe and some other more or less unknown and variable factors we are satisfied that any permanent improvement in the relations between the two neighbours will be due to changes in their own minds and not to any well-meant advice from ourselves or even from more distant inhabitants of the chemical community. There is a *tempus edax rerum* which cures many ills; a hundred years ago the French were the hereditary enemies of this country; sixty years ago Germany was regarded by many chemists as a sort of spiritual home; it is something like fifty years ago since Bismarck is reported to have said "Next time we defeat the French we shall insist upon paying them an indemnity." A few years later he is reported to have said, "If I could live again I should be a Republican; government by Kings is government by women, and if they are bad women it is bad, and if they are good women it is worse." The country which welcomed Hofmann and allowed him for paltry reasons to return to his fatherland, has altered its views in many respects; the aspirations of Germany ten years ago were different from those of fifty years ago; all has changed: the whole map of Europe has been reshuffled and we cannot yet tell whether it is in a state of stable or unstable equilibrium. There is some sort of radio-activity about the waters of the Rhine, some emanation, fatal to tranquillity. Whether Mr. Baldwin was indiscreet enough to sample it we know not. But from the time of Julius Cæsar to that of Clovis, from the period of Charles Martel to the reign of Hugh Capet, throughout the Middle Ages to the campaigns of Marlborough and thence to the defeat of M. Poincaré at the recent election the Rhine has been in a state of ionic activity. Some day mankind will look back on the relics of the disturbances just as Professor Joly sees in small haloes in archæan rocks the evidence of past disturbances resulting from activities of a character too great for the surroundings. We suppose the truth is the Rhine Valley affords no good boundary. Even when the Franks occupied both sides of it there was hardly a permanent peace; it is a poor frail thing compared with the North Sea. If only it could be converted into a Channel as stormy as ours! What could we not contrive if it were a range of mountains? *Que ne pourrait le lion, s'il était singe?* In America somewhere the authorities have dissolved iodides in the reservoirs; a few bromides dissolved in the waters of the Rhine Valley would calm a lot of turbulent spirits. But neither the French nor the Germans are notorious as water drinkers. We are afraid there is nothing to trust to except envious and calumniating time.

Cambridge witnessed what may well prove to be an event of the first importance in the opening of the Sir William Dunn Laboratories for Chemistry in its relations to Life, by the Chancellor, Lord Balfour, on Friday last. That a City merchant should leave the residue of his estate with directions to use it for the "alleviation of human suffering," and that his executors, the Directors of the Commercial Union Assurance Co., should have interpreted the instruction in the wise way they have, is a circumstance of happy augury. At last, we have the fact publicly recognised, that chemistry is a science to be thought of in connexion with medicine. The Chancellor was far-seeing enough to assert, that even that dread scourge of mankind, Cancer, may well have its secrets disclosed through chemical inquiry. Thus far, we know, the efforts of pathologists have been exerted in vain. Chemists throughout the world will desire to congratulate Prof. Gowland Hopkins that he has at last attained to this crowning position in his unwearied efforts to develop a declared school in the borderland regions of chemistry and biology. In accepting the gift, however, the University incurs a grave responsibility, as it is in some measure promoting the subdivision not merely of chemistry, but also of botany and physiology in an unhappy manner.

The new school can only be a success, if the workers are specially qualified both as chemists and biologists—double firsts, in fact. There is already obvious, in the school, an undesirable tendency to specialise at too early a stage; we will be open and also say, that it is probably too much the resort of women students, who cannot be expected to bring to the study of the subject that breadth and originality of outlook and the acute powers of observation that are essential to progress. After the ceremony, visitors engaged in an orgy of interesting demonstrations, beginning with "Enzyme Activities" (tea and toast), and ending with the "Electrical Determination of Acidity." Evidently, Cambridge has some store of sanity. We can only hope that "acidity" may long prevail, and flourish, in memory of Sir William Dunn and his altogether uncommon sense. The full-dress banquet, in the Great Hall of Trinity College, in the evening, was a fitting conclusion to the day. Henry VIII. looked down upon us, and we could not help feeling that the adoption of his attitude and methods might not be inappropriate, at times, even to-day. The Master, in proposing the health of Prof. Hopkins, was happy in his allusion to Tennyson's pregnant verse—which might well be inscribed on some one of the many whitened walls of the new building:—

Flower in the crannied wall,
I pluck you out of the crannies;
Hold you here, root and all, in my hand,
Little flower—but if I could understand
What you are, root and all and all in all,
I should know what God and man is.

CHEMICAL LITERATURE IN CHINA

By WILLIAM H. ADOLPH, Ph.D.

A chemical philosophy flourished in China in the ages gone by, but scientific thought has been dormant for as much as four or five centuries. A revival of interest in things chemical has been set in motion by a few sparks from the West. At the present time much thought and energy is being spent toward putting chemistry in China again on a basis where it can support itself. This is marked by the rapid development of a chemical literature.

For many years such research material as was not published abroad in European or American journals found its way into the *China Medical Journal*, the organ of the association of foreign medical men in China. The old numbers of this periodical, together with the early volumes of the *Journal of the North China Branch of the Royal Asiatic Society*, contain many interesting notes and observations on things chemical and on the chemical industries of old China. Ten years ago those conducting chemical research in China had great difficulty in finding appropriate means of publication. The *Far Eastern Review*, a monthly dealing essentially with the field of commerce and industry, became the repository for a number of these, and others were scattered about in directions that are now difficult to trace.

With the desire to foster more intensive work in scientific study and research, the Science Society in 1916 began the publication of *Science*. This appears monthly in Chinese; occasionally articles appear in English or in German. Last year appeared the first volume of the *Transactions of the Science Society*, all the articles being in the English language. Next in importance comes the *Journal of the China Society of Chemical Industry*. This was started in 1923, and is published twice yearly in Peking, also in Chinese. This society, like the Science Society, is largely composed of Western-trained Chinese and is organising sections throughout the country.

Mention should also be made of the new *China Journal of Science and Arts* which has become the official organ of the Shanghai Chemical Society. The *Lingnaam Agricultural Review*, started in 1922, published at the Canton Christian College, and the *Philippine Journal of Science* have served as media for a number of important chemical papers emanating from China. Several of the Government colleges have published science journals covering the field of chemistry. While much of the material that has appeared in these—and it has all been in Chinese—cannot be classed as original material, it has been very valuable in stimulating an interest in pure scientific investigation.

Omitting all mention of Chu-hsi, the great scientific writer of the Sung Dynasty, and his fellow labourers of 800 years ago, it can be said that the writing of modern chemistry text-books for China began with the appearance of Dr. Fryer's chemistry books about 1870. Dr. Fryer found his greatest difficulty in the terminology, but he boldly invented new names and new Chinese characters for elements and classes of compounds where necessary. Gillison's translation of Luff's *Chemistry* followed in 1905.

The ten-year period from 1905 to 1915 represents the period of Japanese influence, when students returned from Japan and translated the text-books which they brought back with them. Most of these Japanese texts were in turn descended from German prototypes, and the final result was an unrecognisable second-hand reproduction of an excellent original. This influx of Western science by way of Japan has had a lasting influence on the chemistry of China. Most of the inorganic terms in Chinese are those which came in this way from Japan. Practically all of the texts which were the product of this period have filled their usefulness and gone.

The period beginning with 1915 is the period of direct Western influence. American, British and German texts were introduced into the schools in large numbers and used in the original languages. But now many text-books are appearing which, while based on Western models, keep the special needs of the Chinese student in mind and attempt to weave into the text the Chinese background.

The present text-book situation is a poverty-stricken one. Most of the texts in use are of the imported type. There are as yet no text-books either for colleges or for middle schools which can be said to interpret the science of chemistry successfully in terms of the everyday life of China. Such texts could appear either in English or in Chinese, or companion volumes in both languages. Now that the fundamentals of the scientific terminology are settled, there is a desire to have an increasing number of the new text-books appear in Chinese. Because of a limited demand, only until very recently, however, has the publication of college texts in Chinese been considered a sound venture financially. Several of the efforts of the past were subsidised by scientific societies or were private ventures which resulted in considerable loss to the authors.

One of the very encouraging aspects of the chemical literature field is the increasing amount of research material which finds its way into the journals published in China. Seven years ago when the writer undertook to handle the abstracts of the China journal for one of the Western chemical societies, there were four periodicals on the abstracting list yielding an average of about six articles per year containing original material which could be considered of importance to the chemical world. Now, the number of periodicals has increased to eight, and the number of articles annually abstracted to about 30.

Probably the most outstanding accomplishment in the field of chemical literature during the last decade has been the fixing of the terminology. The General Committee on Scientific Terminology was started in 1915, and was organised in its present form when the Ministry of Education in Peking decided to make an annual grant toward the upkeep of its work and to add official approval to the lists of terms adopted by the committee. The section on chemistry numbers about 15, and consists of representatives of the leading scientific societies and a few additional members from the universities. The membership includes chemists and chemist-teachers trained in Britain, Germany, France, America, Japan and China.

Two outstanding principles have been followed in the terminology work. It was first resolved, as far as possible, to translate into the Chinese term in each case the fundamental meaning of the Western chemical term, and not simply to transliterate the sound. Second, it was decided to avoid the invention of new Chinese ideographs. This rule has been transgressed in a few cases for the names of the elements and for a few special radicals. It can be said that the general and inorganic terminology is complete. The organic terminology which was the more difficult piece of work, is practically in its final form, but it needs still the test of more vigorous use in the class room before it can be said to be absolutely satisfactory. The organic terminology follows the synthetic character of the Geneva system, and uses recognised Chinese characters for the different classes of compounds.

The stabilising of the terminology is reflected immediately in the increasing tendency to use the Chinese language as a medium of scientific instruction, and for text-book work. There is no doubt whatever that the use of the Chinese language for all these things is the ultimate goal of China. Many of the colleges and universities now give their chemistry courses bilingually, using both English and Chinese in the class-room, and in some places the college courses of the first year or two are given solely in Chinese. Given the text-book material and teachers of equal experience and training, there seems to be no essential difference as to the results obtained, whether the medium of instruction is one language or the other. At the present moment the greatest need for the development of chemical science in China is the preparation of practical text-books, written by Chinese, from the Chinese standpoint, and with Chinese colouring.

Shantung Christian University, Tsinan, China

PULVERISED FUEL

The Importance for Crude Gas Firing

(From a Correspondent)

A great deal is being heard just now about pulverised-fuel firing, with its many obvious advantages. Of particular importance, however, is the fact—perhaps not yet generally realised—that its extreme flexibility of operation has provided a method of burning at high efficiency crude and often low quality commercial gases. Gas firing, with gas of a uniform quality and pressure, is, of course, extremely efficient, equal, or perhaps even superior, to pulverised fuel, but is very rarely used for the obvious reason that it is too expensive.

With ordinary combustible gases given off as a by-product, the best example of which is blast-furnace gas, the matter is very different because such gas is not only low grade, dirty and dusty, but is violently erratic in supply. A somewhat similar problem, although a much easier one, is the burning of good quality coke-oven gas and the surplus very rich gas from low-temperature carbonisation. The flexibility possessed by pulverised-fuel firing, which

can be started up or shut down almost immediately, and the amount of the fuel burnt altered within very wide limits by merely turning valves, means that the fluctuations in a gas supply can be followed and allowed for without difficulty and all the gas utilised whilst maintaining a steady steam output.

The most remarkable example of this, of course, is the famous Ford plant at River Rouge, Dearborn, Detroit, which normally burns 70 per cent. blast-furnace gas and 30 per cent. pulverised coal on some of the largest water-tube boilers in the world, with a normal evaporation of 220,000 lb. of water (from and at 212° F.) each per hour and 350,000 lb. emergency overload. Owing to this great flexibility of pulverised fuel firing a volume of dirty blast-furnace gas of 90-100 B.Th.U. per cb. ft. amounting to about 70 million cb. ft. per 24 hours, and of course greatly fluctuating in amount, is being burnt at the highest efficiency. At the same time also coke-oven gas, tar, oil, or pulverised coke are used when necessary, and it is intended eventually to use pulverised low-temperature fuel.

The possibility of burning mixed fuels in this way, and of supplying pulverised coal to a furnace at enormous ratings is due to the solution of the practical difficulties of pulverised-fuel firing, especially as regards the furnace and the intense heat developed because of the efficiency of the firing with only 20 per cent. excess air. The difficulty is solved by the "Lopulco" water screen (a series of 4 in. steel tubes in the bottom of the furnace to prevent "slagging"), and a large combustion chamber with hollow air-cooled brickwork walls, the heated air being used to supply 90 per cent. of the air required for combustion.

THE CORROSION CAUSED BY PRODUCTS OF COMBUSTION OF COAL GAS

By U. R. EVANS, M.A.

It is now generally agreed that one of the most important causes of the marked corrosion observed in urban districts is the sulphur dioxide produced by the combustion of coal. It is pertinent to ask whether the practice of employing coal-gas in the place of the direct combustion of solid fuel tends to increase or to reduce damage of this character. Since coal-gas invariably contains less sulphur than the coal from which it is made, it is possible to argue that—as regards *outdoor* corrosion—the use of gas mitigates the trouble. But the question of *indoor* corrosion is somewhat different. Whereas no one dreams of burning coal in a room not provided with a chimney, the burning of gas—for illumination, for cooking, for boiling water and for the heating of rooms—is often allowed to take place without any provision being made for the removal of the products of combustion.

A short time ago, the writer had occasion to examine a case where very conspicuous corrosion had been set up in a private house[1]: the trouble occurred in a large, well-ventilated room heated by two hot-water radiators below which coal-gas was burnt directly. There had been special structural objections to the provision of flues, and, at the time of the installation of these radiators, which were the property of the Gas Company, a representative of that Company had advised that the absence of a flue would entail no nuisance of any kind. The radiators had been installed eighteen months at the time of the examination, but had only been used during the winter periods, and then only for a few hours in the day. It was found that the radiators themselves had suffered most severely. The whole of the lower surface of the iron was completely covered with a pale yellowish-brown incrustation, ⅛ inch thick or more, which analysis showed to be mainly ferric sulphate (both normal and basic); the sides of the radiators were covered with numerous great scab-like growths of the same salt, giving to the stove an appearance of having been splashed with mud. These scabs were close together at the lower part, but became less frequent as the top was approached—no doubt owing to the dilution of the moist sulphur dioxide by the air. On one stove a certain amount of ferric oxide was also present. The black "protective" composition had proved quite unequal to prevent attack by the products of combustion. The general appearance of the corroded surface was distinctly reminiscent of that of the specimens of iron and steel exposed to moist sulphur dioxide in the writer's laboratory experiments[2]; the main points of difference were the absence of ferrous iron, and the dryness of the incrustation, due, of course, to the higher temperature prevailing on the surface of the stoves.

Unfortunately the damage was not confined to the stoves. Bronze ornaments were found to be covered with a moist green incrustation, which proved to be basic copper sulphate, with a small amount of carbonate. Brass electric fittings had also suffered. Experience had proved that it was quite impossible to keep silver in the room, since it darkened almost immediately. A marble clock, which had stood in the room, was pitted by the acid fumes, and presented in patches a "frosted" appearance. Washing with water did not remove this frostiness; the patches partially disappeared when the marble was wetted (owing to the fact that the refractive indices of marble and water are less far apart than those of marble and air), but returned when the water evaporated. It was found possible to conceal the disfigurement to a large extent by coating the marble with a thin layer of vaseline, which, of course, did not evaporate.

There was not the smallest doubt that the damage was due to coal-gas; indeed, in no other way could the production of so much sulphate be accounted for; in other rooms of the same house, which were heated by coal-fires or by gas-fires provided with flues, no special corrosion was observed.

The Gas Industry of this country has for many years pursued a sensible policy in considering the interests of the consumers, and in extending help to them—in the form of gratuitous advice, cheap

[1] It would perhaps be unfair to the company supplying the gas to name the locality where the trouble occurred, since the sulphur content of the gas was probably not higher than that supplied in many other places; the town was *not* Cambridge.

[2] U. R. Evans, Trans. Faraday Soc., 19 (1923), 204.

hiring of stoves and in other ways. The growing use of gas is largely the result of this enlightened method of business. It appears, however, that the question of the possibility of damage caused by the products of combustion has, to some extent, been overlooked; it is generally assumed that so long as the combustion is complete (that is, so long as there is no carbon monoxide unburnt) the fumes produced will cause no rust. Since, however, the corrosive nature of the fumes of highly sulphurous gas must inevitably militate against the popularity of coal-gas as a fuel, gas companies might well find it in their own interest to consider whether the sulphur content of their products could not be cut down. Where this is impossible, it would surely be better policy, "in the long run," not to recommend the installation of flueless stoves in rooms where metallic articles are exposed. The question of protective paints for the stoves themselves is evidently a matter to which attention might advantageously be paid; the casual observation that gas is capable of raising huge boil-like excrescences on the metal may raise in the mind of the average man who is not a chemist the question as to whether the burning of such gas is healthy.

The sulphur content of gas varies considerably in different localities. According to Sutton[3], most companies in 1915 produced gas with about 30-40 grains of sulphur per 100 cubic foot. The South Metropolitan Company, since they commenced to decompose the carbon disulphide by the action of heated nickel[4], have produced a gas with only about 8 grains per 100 cubic foot of sulphur—mainly present as thiophene. This is a notable step in the right direction, and it is probable that if all coal-gas were of this standard, it would be true to say that the substitution of coal-gas for coal as a domestic fuel would tend to reduce—rather than to increase the total damage suffered by metal-work (indoors and outdoors) through acid corrosion.

THE POSITION OF THE NITROGEN INDUSTRY IN FRANCE

By MAURICE DESCHIENS

Speaking at the third Congress of Industrial Chemistry held last October by the Société de Chimie Industrielle, in Paris, Prof. C. Matignon said he had calculated that for an average pre-war year, the quantity of nitrogen removed from the French soil by crops amounted to a total of 1,360,000 metric tons, but neglecting the nitrogen removed by forage crops and the annual cuttings of timber, this total fell to 900,000 t. Agricultural experts consider that at present in France, with proper utilisation of various manures and waste products it is necessary to replace in the soil one-third of the nitrogen removed by the crop, *i.e.*, over 300,000 t. With a wheat crop of 103,753,000 quintals grown on 6,578,000 hectares, 50 kg. of nitrogen is removed per hectare, and 17 kg. of nitrogen should be replaced per hectare every year, making a total of 110,000 t. of nitrogen for wheat alone. Apart from wheat, however, all the arable land in France represents a total of 23,618,000 hectares, which, at the rate of 17 kg. per hectare, requires 400,000 t. of nitrogen.

Various workers have shown that French agriculture requires an average of 75 kg. of nitrogen per hectare for a normal crop, and 20 kg. for natural grassland, making a total requirement of 1,540,000 t. of nitrogen. Including, however, farmyard manure, organic waste and manufactured and imported fertilisers, actually 900,000 t. is supplied, leaving a maximum of 640,000 t. of nitrogen, which modern agriculture could employ were it available. As a contrast to these requirements, French agriculture utilised in 1922 only 70,000 t. of nitrogen, of which 82 per cent. was imported. In 1923, out of 66,000 t. utilised, 12,000 t. of nitrogen was supplied by ammonium sulphate from gas works, and 75,000 t. of sulphate of ammonia (15,060 t. of nitrogen), and 260,000 t. of nitrate of soda (39,000 t. of nitrogen) were imported. To these requirements industrial needs have to be added.

This unfortunate situation has led to a strong demand from the farming community for a national policy so that nitrogen can be supplied more cheaply per unit, so that political and economic conditions have strongly influenced the technical point of view. For this reason, at the close of the war (November 11, 1919), a Convention was agreed between the Minister of Industrial Reconstruction acting for the French Government and the Badische Anilin und Soda Fabrik, to guarantee the use of the Haber process in France. This Convention, after debate in the French Parliament, has been approved by the law of April 11, 1924. (This Convention was discussed in *Chemistry & Industry* in the issue of March 9, 1923, pp. 228-229.)

Private industry, however, after attempting to utilise the Haber process, has turned to other processes such as those of Claude, Casale and the cyanamide process. Of late the production of cyanamide has greatly increased, and as the result of an agreement with the Lannemezan factory, France will be in a position to produce 115,000 t. of cyanamide (25,000 t. of nitrogen). The Claude process is employed or about to be employed by a certain number of coal mines (Bethune, St. Etienne, Decazeville, Aniche), which will be producing by the end of 1924, 160 t. of ammonium sulphate daily, equivalent to 11,000 t. of nitrogen yearly, and are capable of producing double this amount by utilising hydrogen from coke oven gases, gases which are also important sources of liquid fuels and thus affect the solution of the national problem of liquid fuels. Utilising the same source of hydrogen, the coke-ovens of Dourches and of Lens, will, by means of the Casale process, produce 150 t. of ammonium sulphate daily, or a total of 11,000 t. of nitrogen per annum, which can be doubled.

Private industry could thus produce, by means of the Claude and Casale processes, 44,000 t. of nitrogen at the end of 1924, and if the cyanamide is included a total of 69,000 t. of nitrogen might be attained. Neglecting the new processes, however, the actual production is of the order of 19,000 t. of nitrogen.

[3] L. N. Sutton, J. Soc. Chem. Ind., 34, (1915), 14.
[4] E. V. Evans, J. Soc. Chem. Ind., 34, (1915), 9.

By means of the Haber process of which the installation at the Toulouse factory has been approved by Parliament, it is intended to produce 36,000 t. of nitrogen per annum at some future date. The law which made this possible has an important effect on the French nitrogen policy, for in addition to approval of the agreement with the B.A.S.F., it creates an industrial national office of nitrogen with the sole object of manufacturing and selling nitrogeneous fertilisers and products and compounds related to such manufacture. It could begin manufacture at any place considered suitable by its administrative council, and utilise all methods for producing nitrogeneous products of which the patents had been acquired, subject to approval of the ministers of public works and of finance. Such manufacture would not have any other character of monopoly than that conveyed by the patents acquired.

The National Industrial Nitrogen Office at Paris is under the authority of the Ministry of Public Works and administered by a committee of 18 appointed by that ministry, two representing the ministry of finance; 2 that of public works; 3 that of agriculture; 2 that of war; 3 representing agricultural associations: 2 chambers of commerce; 1 power stations; 1 coal producers; 2 specialists in the nitrogen industry; and supplementary members can also be appointed. The Committee is appointed for three years and can be re-elected. Bonds re-payable in fifty years can within certain limits be issued by the Office to cover the cost of establishing and developing the enterprise, interest and extinction of the bonds being guaranteed by the State, and any profits are to be paid into the Treasury. It will thus be seen that by the side of the rapidly growing privately-owned nitrogen industry, a State nitrogen industry is established under a form completely different from that intended in the first Bill placed before the Chamber of Deputies (a company with a capital of 50,000,000 fr., of which 30,000,000 was to be provided by the State and 20,000,000 by private groups). Only the future will show how these parallel industries will succeed. It appears probable that there will be an economic struggle, and it seems likely that this close competition will enable farmers to obtain the nitrogen that they at present lack, in great quantity and at cheaper rates.

THE "SAND-LIME" BRICK PROCESS

An Interesting Scienitfic Development

Scientific methods are spreading surely, if slowly in almost every industry, and good examples of this, particularly interesting to the technical chemist, are the sand-lime brick, and the similar products made from ashes, clinker and blast furnace slag. The sand-lime process consists essentially in mixing sand with 5-10 per cent. of slaked lime, according to the quality of the lime, forming this into a semi-dry mass with water, passing it into a brick moulding machine operating at two tons per square inch pressure, and then exposing for 10 hours in closed cylinders to steam at a pressure about 120 lbs. per square inch, that is, a temperature of approximately 350° F. The main factors in the process are that the lime shall contain no trace of unslaked lime, CaO and that the mixing is of a most thorough character. In these circumstances the lime combines with a portion of the sand to form hydrated calcium silicates, which bind the whole mass into an intense hard, close-grained, homogeneous product, the bricks somewhat resembling natural stone in appearance and mechanical properties.

The whole process can be carried out complete from the raw materials to the finished bricks, in 24-36 hours, a striking difference from the many months of ageing and maturing necessary in preparing ordinary burnt clay bricks, whilst the method is cheaper and has the great practical advantage that sand occurs almost everywhere. From a chemical point of view it is very curious that the lime must not contain the slightest trace of unslaked lime, as otherwise the bricks either expand or become distorted, or they are somewhat weak and friable, whereas with no free lime the "sand-lime" brick is unquestionably superior to the ordinary brick.

The important influence of thorough slaking of the lime appears to have first been realised by Mr. E. R. Sutcliffe, one of the pioneers of this process, of Messrs. Sutcliffe Speakman and Co., Ltd., of Leigh, Lancs, who are specialists on the sand lime and similar type of bricks.

For some unaccountable reason there has always been a prejudice in Great Britain against the use of these bricks. As regards the practical success of the sand-lime brick it may be stated in the first place the present output of such bricks in the world to-day, in the United States and Canada, and on the Continent, particularly Germany, France and Belgium, is about 2500 million per annum. Anyone can go to the Continent and see hundreds of public buildings and thousands of houses that have been built with them during the past 25 years.

From the point of view of chemical, mechanical and physical tests in the laboratory their valuable properties are even more convincingly proved. Thus they have greater resistance to crushing strain than ordinary bricks, and as an example the average crushing strain in a given series of investigations was 5132 lb. per square inch, that is, 330 tons per square foot, whilst the first slight cracking did not appear until the pressure reached 4877 lb. per square inch, that is, 313·6 tons per square foot. Also they are less absorbent to water than ordinary bricks: they possess equal porosity as regards air. Again there is the great practical advantage that every brick is a "facing" brick, that is to say, they are all what may be termed mathematically straight and of equal size, without any sign of twisting, bulging or distortion, so that less mortar is required to lay them, and it is much easier to obtain the most efficient results with plaster because of the smooth surface. Further, they are especially pleasing and artistic in appearance—the colour depending on the sand used—and a building constructed of them has a particularly distinctive look, which is aided by the uniformity of size, already mentioned, and the small amount of mortar.

CHEMICAL PRESERVATIVES IN FOODSTUFFS

By ALBERT E. PARKES, F.I.C.

The question of the use of chemical preservatives in foodstuffs is now under consideration, but before opinions are expressed concerning their harmlessness or otherwise, more definite knowledge is required as to how, and to what extent, they act on living matter and vital functions. The quantities of some chemical substances necessary to preserve different foodstuffs has often been stated, but the amount of information at present available regarding their effects on the human system is very small and is of so contradictory a character that it is of little value. In the absence of authoritative standards, with few exceptions, Public Health Officials when taking action against manufacturers for the excessive use of preservatives have been placed in the unfortunate position of having to prove liability of injury to health. This in most cases, owing to lack of scientific information, has been difficult, resulting frequently in the failure of the proceedings.

Local Authorities have, therefore, been placed in the position of having to consider seriously whether they were justified in instituting proceedings which could only be supported by evidence of doubtful value. Manufacturers of foodstuffs have in consequence been in some measure unrestricted in their choice of preservatives and the extent to which they could use them.

All naturally occurring non-living organic matter, including foodstuffs, is, in a varying degree, and under certain conditions, liable to decay or decomposition, the change being invariably caused by the action of living micro-organisms. The process of preservation consists in employing means to prevent this change, either by destroying the active organisms concerned and adopting methods of subsequent protection, or else such means as will arrest their action, which means may be either physical or chemical.

The principal life functions of all organisms are nutrition, growth and reproduction, and this applies to the individual cells of living tissue, animal or vegetable, and to unicellular micro-organisms. For these functions to be operative in the cell, suitable conditions of temperature and moisture are essential, and the food for nutrition must be in a soluble condition, capable of being diffused through the cell-wall. When micro-organisms are active the protoplasm of the cells secretes specific enzymes or digestive juices which break down by hydrolysis complex indiffusible organic matter into simpler forms suitable for their needs, and following nutrition, growth and reproduction inevitably occur. Some tissue cells specialise in enzyme secretion whilst others are concerned with growth and reproduction only, and in this way they differ somewhat from unicellular micro-organisms where there is no differentiation of functions. No change will occur if we keep organic matter under conditions of temperature unsuitable for the vital functions of micro-organisms. A similar state of stability may be obtained by decreasing the amount of moisture below that necessary, or by the addition of some substance toxic to the organism, in suitable concentration.

At sufficiently high temperatures all organisms and their enzymes are destroyed, and this ideal condition should be aimed at in cooked foods. If the food after cooking has to be kept for any length of time the access of fresh organisms must be prevented. This process has a certain limited application in the canning and bottling industries. Low temperatures do not destroy all organisms, but their activities are almost completely arrested, and enzyme action is at a minimum. This method, known as refrigeration, is largely employed for the wholesale preservation of raw foodstuffs. Chemical preservatives may be divided into two classes. Those substances which have, or may have, themselves, directly or indirectly, some definite food value or stimulative action, such as alcohol, sugar, glycerin, acetic acid, common salt, and essential oils, to the use of which in moderation no objection can be raised, and those substances which, whilst definitely toxic, will, when the concentration is sufficiently low arrest the development of micro-organisms without actually destroying them.

Many chemical substances have been tried at various times for this purpose. Amongst the commonest now used are:—boric acid and borax, formaldehyde, sulphur dioxide and its compounds, salicylic and benzoic acids and their salts. Some substances possess these properties, but are definitely prohibited for use in foodstuffs owing to their known affinity for, or action on, protein matter. By combining with the proteins of the tissue cells they would tend to become cumulative and produce toxic symptoms. Such are the compounds of lead, copper, mercury, arsenic, etc., and amongst these may also be classed substances like phenol, caustic alkalis and mineral acids. Whether any of the commonly used substances can be consumed without injury to health is still an open question. Undoubtedly the ideal chemical preservative has yet to be discovered.

There are two aspects of the main question to be considered. There is the action of the preservative, if any, on the constituents of the food itself, especially the proteins, and the action of the preservative after ingestion on the system, especially the effects on the enzymes of the digestive juices of the mouth, stomach, and intestines, which are of a protein nature. There is some evidence of the former. Formaldehyde, for instance, when added to milk combines with the casein rendering it less easily digested, and alum which at one time was occasionally added to flour had a similar action on the gluten. The action of like substances on the digestive organs can be easily imagined. From the point of view of health the question is not so much the degree to which preservatives will arrest the development of micro-organisms as the effect they will have on enzyme action, this being the basis of all digestive processes, and the extent to which they are absorbed and eliminated by the system. If the growth of the organism is arrested it can be safely assumed that the nutritive function

is also impaired, and the cell will cease to secrete enzymes. That this is so is shown by the fact that saccharine solutions after treatment with sufficient preservative, undergo practically no change, even although there may be dormant yeast cells present, the small amount of enzyme in each cell being too small to have any appreciable effect.

In the various tissues which help to make up the complicated mechanism of the digestive system are glands composed of the cells whose functions are to secrete the digestive enzymes and the question also arises as to how far these functions are liable to be arrested by the action of chemical substances taken in the form of preservatives. Very little is known about the real action of chemical preservatives and germicides on the cell and its contents, but it may be definitely assumed that substances having an affinity for protein matter will retard or arrest the action of the enzymes of the digestive juices and the use of these should be absolutely prohibited. The effect on cell growth and reproduction is also important and should be taken into consideration. If the death of the cell is caused definite injury to tissue will undoubtedly result. An exhaustive series of experiments by investigators of recognised authority should be undertaken to study the effect of any chemical substance possible to be used for food preservation, on enzyme action generally and on cell growth. It would probably be found that some substances now regarded as harmless, owing to their action ought to be prohibited, and it may be discovered that others, whilst arresting cell growth, have little or no effect on enzyme action and consequently could be permitted.

In this direction attention might be paid to some of the coal-tar dyes, (J.S.C.I., 1922, 134T), and to the newer synthetic antiseptic drugs, assuming a safe preservative for foodstuffs is necessary and desirable Wiley's classic experiments carried out on "living squads" though interesting, are inconclusive, conscious sensibility of the subject being an important factor. Until such a series of experiments as those suggested has been conducted successfully, opinions on the use of chemical preservatives in foodstuffs ought to be expressed with caution.

74, Foyle Road, Westcombe Park. S.E. 3

BINDING THE "JOURNAL"

As a number of inquiries relating to arrangements for binding the *Journal* have been received, it is desirable to call attention to the offer by Messrs. W. Speaight and Sons, Ltd., the printers of this *Journal*, to undertake the binding at the following prices per volume :- Complete *Journal*, full cloth 13s. 6d., half-leather 15s. 6d.; Chemistry and Industry Review only, full cloth 10s. 6d., half leather 13s. 6d. Those wishing to take advantage of this offer should send their *Journals* direct to Messrs. Speaight, at 98-99, Fetter Lane, London, E.C. 4.

FORTHCOMING EVENTS

May 15. CHEMICAL SOCIETY. Ordinary Scientific Meeting at Burlington House, Piccadilly, W. 1, at 8 p.m. "The Bromo-derivatives of 1-Methylglyoxaline and the Constitution of 'Chloroxalmethylin,'" by I. E. Balaban and F. L. Pyman. "Synthesis of Amygdalin," by R. Campbell and W. N. Haworth, and "Reactivity and Radiation. The Photochemical Union of Hydrogen and Sulphur," by R. G. W. Norrish and E. K. Rideal.

May 16. INSTITUTION OF MECHANICAL ENGINEERS, Storey's Gate, S.W. 1., at 6 p.m. Third Report of the Steam-Nozzles Research Committee.

May 21. BRITISH EMPIRE EXHIBITION. Conferences on "Heredity as the Basis of National and Industrial Efficiency.

May 21. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 8 p.m. (Trueman Wood Lecture) "The Outlook in Chemistry," by Sir W. J. Pope, K.B.E., D.Sc., F.R.S.

May 21. UNIVERSITY OF LONDON, in the Physics Theatre, Imperial College, Royal College of Science, S.W. 7, at 5.15 p.m. "The Optical Effects of Motion," by Dr. P. Zeeman.

May 22. UNIVERSITY OF LONDON, University College Gower Street, W.C. 1, at 5.30 p.m. "On the Nature of Science," Lecture 1, by Prof. A. N. Whitehead, M.A., and Lecture 2, on May 29, by Prof. T. P. Nunn, M.A., D.Sc.

May 27. SOCIETY OF GLASS TECHNOLOGY. Joint Conference with the British Society of Master Glass Painters. Annual dinner in the Hotel Cecil.

May 27. ROYAL SOCIETY OF ARTS, at 4.30 p.m. "The Geology and Mineral Resources of Cyprus," by C. G. Cullis, D.Sc.

May 28. ROYAL MICROSCOPICAL SOCIETY, 20, Hanover Square, W. 1, at 7.30 p.m. "Use of the Microscope in the Examination of Paper," by F. Sheldon Leicester. "The Microscopy of Soaps," by K. MacLennan. "Technical Microscopy," by J. E. Barnard.

June 3. ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, 35, Russell Square, W.C. 1, at 7 p.m. "The Analysis of Motion by Kinematography."

June 3 to 6. EMPIRE MINING AND METALLURGICAL CONGRESS, to be held at the British Empire Exhibition Among other items, papers will be read on the following subjects: —Mining, Petroleum, Metallurgy of Iron and Steel, as well as Non-Ferrous Metallurgy.

June 4. INSTITUTE OF METALS, Annual General Meeting, at the Institution of Mechanical Engineers, Storey's Gate, S.W. 1. "Atoms and Isotopes" by Dr. F. W. Aston, F.R.S.

June 13. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.30 p.m. First of Three Lectures on Physics by Prof. R. A. Millikan. Lectures 2 and 3 to be delivered on June 17 and 19, respectively.

June 16. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 4.30 p.m. "The Mineral Wealth of the pre-Cambrian in Canada," by C. V. Corless, M.Sc., LL.D.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

A preliminary programme appears on this page.

In accordance with the provisions of by-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting: Dr. E. F. Armstrong, F.R.S., *President*; Mr. Julian L. Baker, Mr. C. S. Garland, Sir Max Muspratt, Bart., and Sir Wm. J. Pope, K.B.E., *Vice-Presidents*; Mr. John Allan, Prof. J. W. Hinchley, Dr. J. H. Paterson, and Mr. W. J. U. Woolcock, C.B.E., *Ordinary Members*.

Mr. W. J. U. Woolcock, C.B.E., has been nominated for election to the office of President under by-law 19; Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., have been nominated Vice-Presidents under by-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been re-elected Hon. Foreign Secretary.

Mr. W. A. S. Calder, Mr. W. H. Coleman, Mr. Wm Cullen, LL.D., Mr. F. W. Gamble, Mr. James MacGregor and Mr. J. Arthur Reavell, have been nominated under By-law 24 to fill four vacancies among the Ordinary Members of Council.

A Ballot List will be posted to every member entitled to vote.

J. P. LONGSTAFF,
General Secretary

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

WEDNESDAY, JULY 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. The President, E. Frankland Armstrong, Esq., D.Sc., F.R.S., will give a technical address entitled: "A Neglected Chapter in Organic Chemistry: The Fats." *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.)

THURSDAY, JULY 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*: Annual Dinner of the Society at the Midland Adelphi Hotel.

FRIDAY, JULY 11. *Morning*: Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

SATURDAY, JULY 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

MEETING OF COUNCIL

The monthly meeting of Council was held on May 9, 1924, the President, Dr. E. F. Armstrong, F.R.S., in the chair.

It was reported that the following had been nominated as Ordinary Members of Council:—Mr. W. A. S. Calder, Mr. W. H. Coleman, Dr. William Cullen, Mr. F. W. Gamble, Mr. James MacGregor and Mr. J. Arthur Reavell. There being six nominations for four vacancies, a ballot will be necessary.

The President stated that the Managers of the Royal Institution consider it desirable to celebrate on June 16, 1925, in association with the chief representatives of British chemistry—the Chemical Society, Society of Chemical Industry, and the Association of British Chemical Manufacturers—the centenary of the discovery of benzene by Faraday in the Institution. At the request of the Council, Dr. E. Frankland Armstrong, F.R.S., agreed to act as the Society's representative on that occasion.

The President reported that he had communicated with the President of the Chemical Society regarding "Chemistry House," and that the Federal Council had appointed a Committee to consider the scheme which he had put forward. This Committee has reported to the Federal Council, and the latter body will meet to discuss the report on May 14.

Reports of various Committees were submitted, and 15 members were elected: Home, 7; Overseas, 8.

The next meeting will be held on Friday, June 13, 1924, at 2.30 p.m.

OFFICIAL NOTICE

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready, and copies have been despatched to purchasers.

The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

A Member of the Society may purchase a set of Vols. II to VIII inclusive at the reduced price of £2 2s. 6d., and a Non-Member can procure a set at the reduced price of £3 15s., post free in each case.

LIST OF MEMBERS ELECTED, May 9th, 1924

Alcock, Horace E., The Knoll, Luton, Beds. Chemical Manufacturer.

Brelaz, Noel J. M., 71, Webster Street, Ballarat, Victoria, Australia. Distiller.

Culhane, Miss Kathleen, 34, Brook Green, London, W. 6. Chemist.

Eastaugh, Frederick A., University, Sydney, N.S.W., Australia. University Teacher.

Fakhoury, Nazim, Secondary School, Mansura, Egypt. Lecturer in Chemistry.

Garner, Walter B., c/o F. H. Faulding and Co., Ltd., 307/313, Murray Street, Perth, Western Australia. Pharmaceutical Chemist.

Gunton, John A., University of Western Ontario, University Library, London, Ont., Canada.

Hardy, Frederick, Imperial College of Tropical Agriculture, Trinidad, B.W.I. Professor of Chemistry.

Law, Herbert Edward, Lauriston, Palo Alto. Box 245, California, U.S.A. Research Chemist.

Sewell, William G., "Kingsmead," Selly Oak, Birmingham. Lecturer in Chemistry.

Tagg, Samuel, Gas Offices, Preston. Gas Engineer.

Uchida, Shojiro, c/o Mr. Mayard, 2 Moreton Terrace, Old Brompton Road, S. Kensington, London, S.W. 5. Engineer.

Van Schaack, Robert H. Jr., Van Schaack Bros. Chemical Works, 3358, Avondale Avenue, Chicago, Ill., U.S.A. Manufacturing Chemist.

Wallis, Edward, 20, Guildford Road, South Lambeth, London, S.W. 8. Assistant to Consulting Chemist.

Yuill, John L., 3, Hawthorn Place, New Earswick, York. Bio-Chemist.

SOUTH WALES SECTION

On Tuesday, April 29, members visited the Landore works of Messrs. Vivian and Sons, Ltd., by courtesy of the directors. The party, who were conducted by Captain Hugh Vivian and Messrs. Taverner and Hill, saw the copper smelting works, sheet mills, power house, fertiliser works, foundry and acid works. A new Garrett articulated locomotive was of much interest; it is capable of taking the same sharp curves as the ordinary four-coupled small works loco., but consisting as it does of two separate driving units (one at each end of the locomotive, but each mounted as a bogie) it is actually capable of hauling more than double the load of a single engine.

A special meeting of the Section was held, at which a vote of condolence with the widow of the late Mr. H. J. Bailey was passed. The party then visited the laboratory, where, besides the routine work, which occupies a staff of about 25, a large amount of research is conducted under Mr. Herbert J. Williams, F.I.C. (chief chemist) and Mr. L. Taverner (metallurgist). This concluded a very full, and interesting afternoon, for which members are much indebted to Messrs. Vivian and Sons, and in particular to Capt. Hugh Vivian, Mr. L. Taverner and Mr. Hill (chief engineer).

SOCIETY OF PUBLIC ANALYSTS

Mr. G. Rudd Thompson presided over the meeting held on May 7, five papers being read.

The "Estimation of Sugar in Urine by means of Fehling's Solution with Methylene Blue as Internal Indicator," was discussed by J. H. Lane, B.Sc., and Lewis Eynon, B.Sc. The sugar in urine can be accurately estimated by means of Fehling's solution with methylene blue as internal indicator, provided the urine be first rendered neutral to litmus. Defecation of the urine with normal lead acetate and removal of the excess of lead with potassium oxalate enables a sharper end-point to be obtained. This treatment does not remove any reducing sugar, but removes a small amount of reducing non-sugar substances (equivalent to about 0·02 to 0·03 per cent. of dextrose). The results obtained by the method agree closely with those given by Gerrard's cyano-cupric method, but are considerably lower than those given by Pavy's method, this difference being attributed to the estimation of non-sugar substances in the latter method. Methylene blue can also be used as an internal indicator with Pavy's or with Benedict's solution.

Mr. J. J. Considene described the construction of, and method of using three simple forms of hydrogen electrode, which can be readily made from apparatus used in every laboratory, including an electrode for general use, a "micro" modification of this, and a modification of the capillary form of electrode, which has been found useful for fluids of low conductivity.

A "Note on the Recognition of Hydrogenated Oils" was presented by K. A. Williams, B.Sc., and E. R. Bolton, F.I.C. During the hydrogenation of oils iso-oleic acid is formed. This acid does not occur in nature; it is an isomer of oleic acid, has an iodine value of 90, and is characterised by the insolubility of its lead salt in organic solvents, in this respect resembling the saturated fatty acids and not the unsaturated ones. The authors suggest that for the detection of hydrogenated fats the iso-oleic acid content of the fat should be determined. This is done by performing the ordinary lead salt ether separation of the fatty acids, by which the iso-oleic acid is separated from all other unsaturated acids, and appears in the fraction containing saturated acids: in this it is estimated from the iodine value. The effect of the use of various solvents for the separation is recorded, methylated ether or alcohol being recommended. Figures are given showing the amount of iso-oleic acid to be expected in fats hydrogenated to various degrees, and examples of the application of the method are discussed.

"Notes on the Analyses of Milk Powders and Condensed Milks" were given by Dan W. Steuart, B.Sc. The citric-acid content of full-cream milk powders averaged 1·16 per cent. and of skim-milk powders 1·55 per cent., equal to about 0·144 per cent of anhydrous citric acid in the original milk. The citric acid content of pure milk products is equal to about one-fifth of the ash. Analyses of milk powders and condensed milks are given. Lactose is estimated

by the reduction method of Lane and Eynon (using methylene blue as an internal indicator), after removing the protein and lime.

ROYAL MICROSCOPICAL SOCIETY

Mr. A. Chaston Chapman, F.R.S., presided over the meeting on April 16, when Dr. T. Goodey, D.Sc., read a paper on "Recent Work on Nematode Life History," describing recent investigations into the life-history of several nematode worms parasitic in plants and animals. The following came under review: *Tylenchus dipsaci*, causing stem diseases in a number of economic plants; *Tylenchus tritici*, causing "cockles" in wheat; *Allantonema mirabile*, from the body-cavity of a weevil; *Hæmonchus contortus*, the stomach worm of sheep; *Ancylostoma duodenale*, the human "hookworm"; *Syngamus trachealis*, causing "gapes" in chickens; *Ascaris spp.* of various animals, and *Habronema megastoma*, from the stomach of the horse. Prof. E. W. Carlier, M.D., B.Sc., communicated a paper by Mr. T. H. Rogers, on "Electric Methods of Staining the Radulæ of Mollusca."

At the meeting of the Industrial Applications Section, on April 23, the Hon. Sir Charles Parsons, K.C.B., D.Sc., F.R.S., took charge of the chair. Miss Annie D. Betts, B.Sc., read a communication on "The Practical Use of the Microscope in the Bee-keeping Industry," in which she showed that the principal use was in diagnosing diseases of bees, and in deciding questions such as colour inheritance and purity of breed. Probable changes in the Merchandise Marks Act might open up a wide field of work for the consulting microscopist in deciding the country of origin of honey samples. A knowledge of the forms of pollen-grains enabled the bee-keeper to determine, by examining the pollen collected by the bees, the times of the flowering of the local nectar and pollen plants, information of great practical value.

Mr. C. F. Hill read a communication by Mr. Sydney R. Wycherley, on "Fibres, Analytical and Economic." The study of fibres was of great interest, not merely to the research worker, but for practical purposes. From the analytical point of view it was desirable to make standard sets of slides, which would become the key slides from which materials to be tested could be judged. In examining various products the plant hairs, being difficult to destroy, and often characteristic in form, provided a means of investigating the purity of a compound and the amount, if any, of the adulteration. The study of fibres from the economic point of view was also of great value. Cotton fibres were characterised by a peculiar twist and the regularity of that twist together with the thickness of the hair itself, was one of the tests for the quality of the cotton fibre used. In addition, animal fibres, such as wool, formed important lines of investigation. The scale marks covering the outer cuticle of the wool were very constant in various qualities of wool, and formed an important character in testing for quality.

ACADÉMIE DES SCIENCES

On April 22, Dr. Roux communicated a paper by M. Ramon on "anatoxins," a name given by the author to products derived from toxins or from vegetable or animal toxic proteins, which, on undergoing suitable treatment, such as the addition of formaldehyde, lose their toxicity, but still act towards the antitoxin as if they were true toxins, and also confer active immunity. Mr G. Bertrand said that in studying snake poisons, he had obtained similar results.

On April 28, M. Mangin described the effect of thorium X on various vital phenomena, and M Branby discussed the theory of the formation of ozone by electrical action.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

On May 2 the metallurgical and mineral industries group met, under the presidency of M Gall, to hear a paper by Prof. C. Matignon, on "The new physico-chemical methods of qualitative analysis by means of X-rays. After paying tribute to the work of Sir J. J. Thomson and of Dr. Aston, the speaker described the extraordinary delicacy and sensitiveness of these new methods dealing with infinitesimal amounts of matter. Thus, the carbon atom weighs only one milliardth part of a milliardth part of one-hundredth of a milligram, yet so small a mass could be determined with the greatest precision. In a mixture, all the elementary constituents could be identified by their mass. In one c.c. of air, containing only 5 millionths of helium, the presence of that element could readily be distinguished; in fact the 5 millionths of one c.c. of air already contained 10^{14} molecules of helium, and thus furnished the material for identification. By mechanical methods it had been made possible to weigh particles that are more than 10^{10} times smaller than the smallest particles visible in the ultra-microscope. Atoms and molecules are ionised positively, and possess a magnetic and electric charge; when moving at a certain speed they undergo deviations depending on the speed and mass of the particle, so that when this double deviation had been measured, both speed and mass could be calculated, the deviations being determined by the points of impact on a photographic plate. No longer of purely scientific interest, these methods were now being utilised in metallurgy, paper-making, and tanning-extract making.

Monsieur A. Bigot then read a paper on the treatment of towns' refuse, first calling attention to the properties of "basic glass," a material which resisted ordinary acids, and was fairly hard, being more resistant to mechanical agents than most rocks. By treating the slags obtained on incinerating town's refuse, basic glasses had been obtained, and this led to a study of the methods of disposal of town's refuse. Part of this refuse was utilised by agriculture; another part was incinerated under boilers to raise steam for electrical generation, and the slag was discharged, but the process ran at a loss owing to the cost. Another part was utilised under a power plant,

but the residue was utilised in making sand-lime bricks, the gross profit being 3 fr. per ton of refuse treated, even if the process ran at a loss. The residue contained excess of sulphur and carbon, as the conditions of combustion were bad, and sand-lime bricks made from it blackened in the air, and became covered with efflorescences, and rusty-looking, consequently being of little use. By means of improved methods, the residues could be produced of a quality suitable for making bricks or cement; and by fusing with suitable materials at high temperatures, glasses could be obtained for the manufacture of bottles, glasses, recipients, insulators and the like. Such a process provided the means for the rational and profitable utilisation of town's refuse.

FINSBURY TECHNICAL COLLEGE

The London County Council has addressed a letter to the council of the City and Guilds of London Institute informing them that after consideration of all the circumstances the Council has reluctantly come to the conclusion that it will be unable to continue the financial grant in aid of the college after July 31, 1926. The County Council feels that it is difficult to justify the comparatively large expenditure which at present falls on public funds in connexion with the maintenance of the college, in view of the fact that there are a number of other institutions making provision for training in engineering and chemistry which could absorb, without difficulty, the number of students now attending the Finsbury Technical College. In these circumstances the Council of the Institute states, according to *The Times*, that there is no alternative but to make arrangements to close down the college in July, 1926, or possibly before that date.

NEW BIOCHEMICAL LABORATORIES AT CAMBRIDGE

On May 9, Lord Balfour opened the new Sir William Dunn Biochemical Laboratories at Cambridge, thus making it possible to concentrate all the activities of the School of Biochemistry in one building. The late Sir W. Dunn left the residue of his estate for the "alleviation of human suffering," and his trustees decided to allocate £210,000 for the new laboratories, which have cost £96,000 and contain a large general laboratory at the top of three stories as well as 20 well-equipped rooms for research.

The Council of the Institution of Civil Engineers has made the following awards in respect of papers read and discussed at the ordinary meetings during the session 1923-1924:—A. Telford Gold Medal to Prof. C. E. Inglis, M.Inst.C.E.; Watt Gold Medals to Mr. H. N. Allott, M.Inst.C.E., and Mr. S. L. Pearce, M.Sc.Tech., M.Inst.C.E.; Telford Premiums to Mr. A. J. Martin, M.Inst.C.E., Dr. H. E. Hurst, Mr. D. A. F. Watt, D. H. Remfrey, B.Eng., Assoc.M.Inst.C.E., and William Burnside, Assoc.M.Inst.C.E.; a Crampton Prize to Mr. T. R. Nolan, B.E., M.Inst.C.E.; and a Manby Premium to Mr. H. T. Tudsbery, M.Inst.C.E., and Mr. A. R. Gibbs, Assoc.M.Inst.C.E.

FEDERAL COUNCIL FOR PURE AND APPLIED CHEMISTRY

DYESTUFFS INDUSTRY

The following letter was recently sent by Sir William Pope to the Rt. Hon. Sidney Webb, President of the Board of Trade.

Sir,—The Federal Council for Pure and Applied Chemistry is elected by the principal scientific and technical societies interested in chemical subjects—18 in number—and is concerned with those large corporate interests which are common to the electing bodies. The Federal Council desires to place before you certain views concerning the contemplated agreement between the British Dyestuffs Corporation and the German combine known as the Chemische Interessen Gemeinschaft.

It will be remembered that British Dyestuffs, Ltd., which later became the British Dyestuffs Corporation, was created with Government support, financial and otherwise, with the express object of rendering this country independent in future of German domination in the dyestuffs industry. It was recognised universally at the time, and nothing has since transpired to weaken the conviction, that a flourishing and independent coal-tar colour industry is essential to Great Britain.

Although no official information as to the nature of the agreement contemplated between the British Dyestuffs Corporation and the Interessen Gemeinschaft has been announced, yet it has been stated, and without contradiction, that the German organisation is to be under an obligation to render any available and technical assistance, and that the British Dyestuffs Corporation is to be granted a monopoly for the importation and distribution of German dyestuffs and intermediates not produced in this country.

The Directorate of the British Dyestuffs Corporation, though including a number of eminent personalities, is a lay board of which no member has achieved distinction in connexion with dyestuffs manufacture, whilst the directorates of the corresponding German organisations consist of men who have all made brilliant careers in the industry. It would seem to follow that under the arrangement outlined the technical part of the British organisation will ultimately fall under German control. The handicap to the future development of British technical chemical talent thus introduced will be obvious. The state of affairs which prevailed before the war will thus practically become re-established, and the British dyestuff market will be again under German domination.

The granting of a monopoly for importation to the British Dyestuffs Corporation can only result in the extinction of the firms outside the British Dyestuffs Corporation which also manufacture dyestuffs. In this connexion it must be remembered that certain of these firms have been very successful as manufacturers of high-class and other dyestuffs and have thus proved their ability to succeed in the absence of such a handicap as would be imposed by the suggested monopoly of importation.

The dyestuff factories in Germany have proved to be creative centres which have initiated and carried into practice, both profitable and utilitarian discoveries in organic chemistry which have had far-reaching beneficial effects in many important industries and professions. They have introduced large numbers of new substances which have proved valuable in photography and almost every other technological industry which uses organic chemicals; they have also produced great numbers of organic compounds which are of marked value in the treatment of disease. Only a year or so ago the firm of Bayer introduced the organic substance No. 205, which is claimed, and apparently with justice, to be an absolute specific in cases of sleeping sickness; the British Government sent a Commission of German scientific men to Africa to test the efficacy of this material, and at a meeting of the German Association for the Study of Tropical Diseases it was stated that the secret of Bayer 205 must be preserved and used for the recovery of the German Colonies.

The German dyestuff industry may be regarded as a kind of network which carries with it and supports many important technological developments in other branches of organic chemistry; in fact, the staple products separated from coal-tar not only serve in the manufacture of dyes but also constitute the starting materials for the preparation of great numbers of important organic compounds which are not colouring matters. The fact that the German dyestuff industry is under the control of scientific and technical chemists, fully alive to all the important possibilities of their ostensible industry, facilitates the developments of those ramifications which have made the dyestuff industry necessary to a number of industries with which, at first sight, it appears to have no connexion.

It is clear that if the scientific and technical sides of the colour industry again lapse into German hands, and the British organisation merely retains certain merchanting rights, as seems to be indicated by the suggested form of co-operation, all the technical and professional interests which use organic chemical substances will remain dependant on Germany for every detail of progress.

Scientific and technical chemists, of course, recognise that further great advances will occur in connexion with the manufacture and applications of synthetic organic compounds. Immediately after the war, and encouraged by official declarations to the effect that the dyestuff industry of Great Britain would never again be allowed to fall under German domination large numbers of young people took up the profession of chemistry; during the last few years the number of entries for chemical subjects in our Universities and colleges has greatly diminished. The student public is becoming disillusioned; it discerns a tendency towards once more surrendering supremacy in the development of technical chemistry to Germany. This view of the situation has found confirmation in the wholesale dismissals of research chemists from the employ of the British Dyestuffs Corporation; these dismissals are, of course, regretted by all, but they were doubtless necessitated by financial considerations. Large numbers of highly trained chemists are at present out of employment; this cannot but have a seriously depressing effect upon higher scientific studies in this country.

We fully realise that criticism without constructive suggestion is of little value, and we desire to put several propositions before you. These are as follows:—

(1) That any working arrangements which are made should respect the original object of the Government-supported dyestuff scheme, namely, to free the organic chemical industries of this country from foreign domination.

(2) That no one manufacturing concern which has received Government support should be granted monopolies which would enable it to crush other enterprises which have achieved a large measure of success on non-official initiative.

(3) That it should be realised that the coal-tar colour industry is not only an essential part of a widely extended organic chemical industry, but that it is a part of, and is largely dependent on, the whole chemical industry of the country; and that this realisation should be reflected in the composition of the directorate of the British Dyestuffs Corporation and its policy.

(4) That, quite apart from immediate questions of financial return, means should be adopted for developing technical research in organic chemistry in the laboratories of the British Dyestuffs Corporation, for the purpose of utilising the undoubtedly great potentialities as research workers of our chemical students. It may indeed be desirable to finance this educational object by some method independent of the British Dyestuffs Corporation. Our national well-being demands that every effort shall be made for promoting research in chemistry and that no step shall be taken which will tend to throw any part of this duty on any foreign country.

The Federal Council desires to call your attention to the great contributions which this country has made in the past to chemical science and to the manifold activities of our chemical schools at the present time. It expresses its conviction that, given encouragement, the magnificent results of British chemistry during the war are capable of translation into a flourishing organic chemical industry in the near future.

In conclusion we invite your earnest attention to the great progress which has been made in the organic chemical industry of this country under recent legislation; large numbers of organic compounds not previously made in this country on an industrial scale are now being produced as regular articles of commerce.

That this result has been achieved under the difficult conditions of recent years is a happy augury for the future of chemical industry in Great Britain. —I am, Sir, Your obedient servant,

(Signed) W. J. POPE.

President of the Federal Council for Pure and Applied Chemistry

April 8, 1924

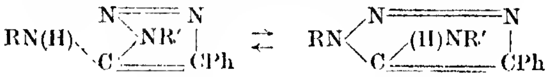
The Right Hon. SIDNEY WEBB, M.P.,

President of the Board of Trade

CORRESPONDENCE

THE AMINOTRIAZOLES

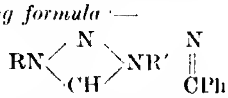
Dear Sir,—In the report (this week's *Chemistry and Industry*) of my remarks relating to Mr. Dutt and Miss Carnelly's aminotriazoles, the printers have garbled some of the formulæ, inserting a 4-membered ring in them in such a way as to suggest the negation of my actual meaning, or, at least, render it unintelligible. Formulæ (i) and (ii), p. 486, should read :—



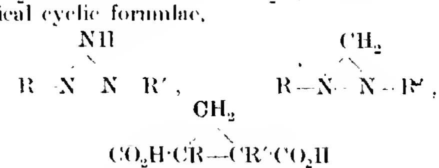
(i) (ii)

(R = phenyl ; R[1] = *p*-tolyl)

And my point, obscured by the misprints, was that this direct interchange is of known type, and that a proof of the effective equivalence in the molecule of R and R′ *does not necessitate a symmetrical 4-membered ring formula* :—

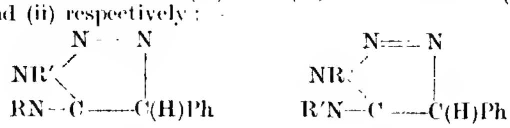


any more than a similar equivalence in such compounds as R—NH · N : N—R′, R—NH · CH : N—R′, or $CO_2H \cdot CHR \cdot CH : CR' \cdot CO_2H$, necessitates symmetrical cyclic formulæ,



for diazoamino-compounds, amidines and glutaconic acids respectively.

The two isomerides actually isolated, which were tertiary bases and were stated to have the properties of anils, are in my view actually anils—namely, the imino-tautomerides (iii) and (iv) of the enames (i) and (ii) respectively :—



(iii) (iv)

They are the more stable forms, but are reversibly convertible into the enames (i) and (ii), these secondary bases being favoured by strong mineral acids :

(iii) → (i) ⇄ (ii) ← (iv)
stable *unstable* *unstable* *stable*

(*excepting as salts in strong acid solution*).

These changes are all of thoroughly well-recognised types, and thus the complex system of polycyclic tautomerides imagined by Mr. Dutt and Miss Carnelly appears to have small foundation.

The question of the intervention of a cycloid in tautomeric change is of such importance that I think it is desirable to correct the confused report which has appeared.—I am, Sir, yours faithfully,

CHRISTOPHER INGOLD

QUALIFIED AND UNQUALIFIED CHEMISTS

Sir,—In your issue of the 9th inst. "Fuel Technologist" asserts that the Institute of Chemistry is right in insisting on chemistry as the essential in dyeing. It would be interesting to have the reasons for this assertion. As a pass B.Sc. with 25 years in the dyeing industry I beg entirely to disagree with him. If "Fuel Technologist" knew of the dyeing problems still awaiting solution, *e.g.*,

(1) The Theory of Dyeing ;

(2) The Action of Light on Dyed Fabrics ;

and had read recent literature thereon, he would at once realise that physics and mathematics are of equal importance in dyeing as in fuel technology, whilst in the industry a knowledge of engineering is also very useful.

In the industrial application of chemistry it is not only scientific qualifications which are required, but of far more importance is the requisite horse sense to adapt oneself to industrial conditions. A qualified chemist plus horse sense is a pearl without price, but failing him an unqualified chemist plus horse-sense is a very good substitute.

Whatever steps are finally taken regarding the necessary legal qualifications of a chemist, it will still be found that the qualified or unqualified chemist who graduates most quickly in the University of Horse-Sense who will secure the highest positions open to chemists. When this problem of qualifications is finally settled, I suppose the qualification test will to be applied to those gentlemen who are subsequently nominated to the presidential chair of the Society of Chemical Industry.—I am, Sir, yours, etc.,

Cheadle Hulme, C. M. WHITTAKER
May 11, 1924

Sir,—I was very interested to read "Fuel Technologist's" letter *re* "Qualified and Unqualified Chemists," and I heartily agree that the A.I.C. should, in most cases, be conferred only upon those who possess "practical" experience. To be a qualified chemist, it is not sufficient merely to possess a certain amount of knowledge ; one should also be able to apply it, either in industry or in imparting that knowledge to others. With this end in view I suggest the following amendment to qualification (2) proposed by "Fuel Technologist."

A.I.C. should be conferred upon those possessing (*a*) B.Sc. (Honours, 1st or 2nd class) ; (*b*) M.Sc. (*c*) D.Sc.—provided the applicant has been engaged in the application of chemistry for, say (*a*) 3 years ; (*b*) 1 year ; (*c*) ——.—I am, Sir, etc.,

AN A.I.C.-TO-BE

PALMA ROSA OIL

Sir,—In your issue of May 9, page 500, we notice you quote Palma Rosa Oil at 19s. per lb., very short supply.

As large importers of this Oil, we should like to point out that we have a good supply now in London, and the price is 17s per lb.—Yours, etc.,

D. WALDIE & COMPANY (LONDON) LTD.,
P. H. CRUICKSHANK,
Secretary

PERSONAL AND OTHER ITEMS

Notes from Canada

Sir William Ellis, G.B.E., D.Eng., has been elected President of the Iron and Steel Institute. The Bessemer medal of the Iron and Steel Institute has been awarded to Prof. Albert Sauveur; the presentation was made during the Annual Meeting on May 8.

The Daly-Alaska Company purposes erecting a mill at early date, at its mine on Portland Canal, B.C.

C. L. St. Clair, of Camden, New Jersey, representing Eastern American and Canadian capitalists, has announced the erection of a smelter, on a deep water site, in Vancouver, B.C. The plant is to cost five million dollars. Erection will commence at once, and will have a capacity of 1000 tons a day.

British Columbia's leading mine, the Premier, on Salmon River, Portland Canal, has declared its first quarterly dividend for 1924. The share capital of the company is $5,000,000, and the first dividend was declared three years ago. The total payments on dividends have been $5,400,000, thus exceeding the capital by $400,000. Stewart, B.C., is the shipping port.

A rich strike has been made at the Dunwell property on Bear Creek, Portland Canal district, B.C. The general run of the mine is equal to the Premier, the ore body having a width of 50 feet and valued at from $20 to $30 per ton, with some rich ore running into hundreds of dollar per ton.

The Dominion Tar and Chemical Co., Sydney, N.S., has an order for creosote, from the Canada Creosoting Co., Trenton, Ont., amounting to one million gallons, which is being forwarded, by tank cars at the rate of 10,000 gals. daily. There is a shipment being made of 4000 t. of pitch to France. The tar from the British Empire Steel Co. amounts to 20,000 gals. a day.

The maple sugar output of the province of Quebec, this spring, has not been as large as anticipated. The sap was not as high as usual in sugar content. The total yield will be about 22,000,000 pounds, valued at about $5,500,000. The sugar campaign extended over seven weeks.

C. E. Wallin, for some years superintendent of the coke ovens department of the British Empire Steel Co. has resigned his position, and will leave shortly for England, where he has accepted another position. He will be succeeded by D. W. Nicholl, formerly Assistant Superintendent.

Hon. Chas. McCrea, Minister of Mines, Ontario, is in England upon official business connected with the mining interests of the province.

Balmer Neilly, B.A., Sc., M.E., Secretary of the Mining Association of Ontario, has resigned and joined the management of the McIntyre-Porcupine gold mine.

The British Columbia Electric Railway is erecting an addition to the gas plant at Vancouver, B.C., costing $400,000, with a capacity of 1,750,000 cubic feet a day, which will be finished and operating before the close of the year. The contract has been awarded to the West Gas Improvement Co., of Manchester, England. The additional plant, of forty vertical retorts, will be placed by the side of the present twenty-four vertical, but of a new type. A bench of Spencer-Bonecourt water-heating steam boilers will be installed. A coke-briquetting plant of 25 tons capacity per diem will also be erected. A large number of subsidiary improvements will be installed to bring the plant up-to-date. A complete ammonia-recovery plant will be one of the features. The company will erect a new gasometer at its Victoria, B.C., works with a capacity of 500,000 cubic feet. The construction is in the hands of R. Dempster and Sons, of Elland, Yorkshire.

The Thunder Bay Paper Co., in which American interests at Appleton, Wis., are interested, is increasing the capacity of its mill from 65 tons a day to 160 tons. The enlargement is to be completed by August 1.

The Fourth International Conference on Soil Science

The International Conference on Soil Science, which is being held in Rome at the International Institute of Agriculture, from May 12 to 19, will be the fourth of a series. The first was held in 1909 in Budapest, the second in 1911 in Stockholm, and the third in 1922 in Prague. The number of communications and reports to be presented amounts to over 200, fundamental questions of soil science being treated in a way that shows the intimate relationship between soil science and agricultural industry.

The proceedings of the Conference will be published in the form of a volume of about 1000 pages, containing all communications, conferences, reports, memoirs, discussions, etc., illustrated with diagrams, graphs, figures and maps. The price to members for copies of the Proceedings is 15s., and to others 30s. Further particulars can be obtained from the Organising Committee of the IVth International Conference on Soil Science, International Institute of Agriculture, Villa Umberto I, Rome, 10.

Reported Spanish Metallurgical Syndicate

It is reported that nearly all the foreign companies that work metal mines in Spain are considering the formation of a mining and metallurgical syndicate, jointly with important foreign metallurgical interests.

Mining and Metallurgy in Canada

The extensive coal areas of Inverness County, Cape Breton, have been secured by the recently incorporated Eastern Collieries Ltd. The chief shipping port will be Port Hastings, and the general management of the mines will be conducted by Alfred J. Tonge, M.E., assisted by T. J. Brown, M.E., at present Deputy Commissioner of Mines for the Nova Scotia government. Both engineers were formerly employed with the predecessors of the British Empire Steel Co. The Canadian National Railway is operating the Inverness and Richmond Railway. Coal depots will be established in various cities in Eastern Canada. British financial men are interested in this undertaking and they will be associated with Canadians on the directorate.

The Coal Industry in France

Production has increased from 31,940,000 metric tons in 1922 to 38,540,000 t. in 1923, thus approaching the normal production of 1913 when 40,840,000 t. was produced. The daily output has risen from 136,147 t. in January, 1923, to 141,680 t. in January, 1924, the latter figure corresponding with an annual production of over 43,000,000 t. Similar improvements in the production of coke suggest that soon an output of 245,000 t. per month can be expected. The consumption of coal has also increased, rising from 59,321,000 t. in 1922 to 66,676,000 t. in 1923, compared with 63,978,000 t. in 1913. Of the consumption in 1923, 58 per cent. was produced in France, but imports of coal have increased from 22,421,000 t. in 1921 to 26,268,000 t. in 1923, whereas imports of coke have decreased from 5,142,000 t. in 1922 to 3,628,000 t. in 1923, and briquettes also show a decrease. The increased imports have come mainly from England, whilst imports from Germany have decreased and those from Belgium remain approximately stationary. Exports have increased from 267,900 t. in 1922 to 3,011,000 t. in 1923.

French Ceramic Industries Congress

The technical congress of the ceramic industry organised by the Syndicat des Fabricants de Produits Céramiques de France, will be held in Paris on June 2 and 3, 1924. The questions to be discussed will include the results obtained from continuous ovens, experimental methods for determining temperatures in ceramic ovens, theoretical and practical study of ventilation in ovens, pulverised fuel and heavy oil as heating agents, use of artificial drying, the plasticity of ceramic products, and many other subjects

Industry in Tonkin (Indo-China)

Anthracite is found abundantly near Hong-hai, and can be mixed with " fat " coals of Thai N'Guyen, the region where, owing to the presence of iron ores, a works is being erected to produce 150 tons of steel per day. Tungsten is also abundant, and although the presence of petroleum is known, actual working has not yet begun. The Société des Ciments Portland de l'Indo Chine manufactures 150,000 tons of cement yearly. Soda and chlorine are manufactured by the Société des Prodoits Chimiques d'Extrême Orient, at Hanoi, and there is a fairly large production of alcohol and bamboo paper.

Canadian Textile Industries

The woollen textile industry of Canada in 1922 was generally considered to have had an unprofitable and unsatisfactory business year. This is not confirmed in the bulletin of Dominion Bureau of Statistics just issued, covering the above period. The total value of products is given as $29,062,751, while the cost of production, including materials was $25,330,812, leaving a favourable balance of $3,731,939 or over 10 per cent. on a total investment of $37,102,382. The value added to their products by manufacture is placed at $15,202,772. Wages and salaries amounted to $7,190,544, of which $1,286,068 were paid in salaries. Cost of fuel $671,154, materials $13,859,979, and miscellaneous expenses $3,609,135.

Canadian Hydro-Power Development

The Hydro-Electric Power Commission of Ontario, is faced with a demand for 53,000 h.p. before the end of 1924, from the Nipigon power plant, near Port Arthur, Ont. It is now calling for tenders for the installation of units five and six which, when completed, will bring the total capacity of the Cameron Falls plant up to 72,000 h.p. The commission is considering raising the level of Lake Nipigon in order that the power requirements of Fort William and Port Arthur may be taken care of.

Natural Gas and Oil in Canada

The Rogers-Imperial Co., while boring for oil five miles north of the International boundary, in the Sweet Grass district about thirty miles of Coutts in South Alberta, struck gas at 2500 feet, and the flow is now estimated at 20,000,000 cubic feet daily. The gas will be tested for gasoline content. This gas well is situated about twelve miles north of the large oil producing district of Northern Montana.

Upper Silesia Zinc and Lead Works

As for some months, the blende roasting and zinc smelting works are producing crude zinc, zinc oxide, zinc sulphate, and cadmium sufficiently to supply the demand while stocks are being added to. The sheet-zinc works have barely been able to maintain their output, while the lead and silver works have been producing less lead, litharge, and silver lately than a few months ago.

LEGAL INTELLIGENCE

THE AFFIX A.M.Inst.C.E.

The Institution of Civil Engineers v. Dey and Roy.

Mr. Justice Tomlin heard a motion by the Institution of Civil Engineers against Birendra Nath Dey and Promod Nath Roy, for an injunction restraining them and each of them from using, or allowing to be used, after or in connexion with the name of B. N. Dey, or in connexion with any profession or business carried on by them, and from printing or writing on any document issued and published by them or either of them the words " Associate Member of the Institution of Civil Engineers," or any letters or words or designation to the same effect. The subject of the plaintiff Society's complaint was that the defendants had employed after the name of the defendant, Dey, the description A.M.Inst.C.E. in the printed headings of letter paper. That was not justified, and it was understood that the defendants were willing to treat the hearing of the motion as the trial of the action, and to submit to a perpetual injunction in terms of the notice of motion and pay the costs. This was

greed to for the defendants, and Mr. Justice Tomlin aid there would be an order accordingly.

For the defendants it was stated that the description had been inserted in the headings of a few letters by inadvertence.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

British Dyes

On the 13th inst., Mr. Sidney Webb (President of the Board of Trade), in reply to Mr. Black, said the values of German reparation dyestuffs received by this country for the years ending March, 1923 and 1924, were respectively £301,400 and, approximately, £94,000. The terms of agreement with the British Dyestuffs Corporation would be circulated in the official report.

Mr. Waddington asked whether any statement had been presented on behalf of the British Dyestuffs Corporation which embodied the heads of the proposed agreement with the German combine, and whether before the agreement could be further advanced the approval of the Government would be given to such statement.

Mr. Webb replied that negotiations between the parties to the proposed agreement were being continued. The Government had been made aware in outline of the terms now being further considered, but until the examination of them was completed he was not in a position to make any statement on the subject.

Mr Sandeman: Can we have an idea when full information will be given on this question, because it is causing a great deal of unrest in the industry?

Mr Webb: The Government is not a party to the negotiations and has no power to intervene except with regard to the exercise of the power given to it under the charter, and that can only be done when agreement has been reached.

Mr Sandeman: Will the House be consulted before agreement is made?

Mr Webb: I cannot say that because we are not parties to the agreement, but I can say that no action will be taken to put in force the powers of the Government without the House receiving notice.

British Exports to Poland

Sir J Brunner asked the President of the Board of Trade whether he was aware that British goods imported into Poland were subjected to higher import duties than French and Belgian goods and whether the Government were taking steps to rectify this discrimination.

Mr Webb replied that a commercial treaty securing the removal of this discrimination was signed at Warsaw in November last and would come into force fifteen days after ratification. He understood that it still awaited confirmation by the Polish President. When this was given immediate steps would be taken by his Majesty's Government to ratify it.

REVIEWS

Pharmaceutical Analysis. By Azor Thurston. Pp. 409. London: Chapman and Hall, Ltd. Price 21s. net.

The title of this excellently printed book is not a happy one. Whatever may be the precise significance of the words "pharmaceutical analysis," the contents of the work have little to do with medicinal drugs, and the range of foods dealt with is limited. Possibly the quite independent volume contemplated in the preface may be intended to fill up the gaps.

The first 78 pages are devoted to instruments, determinations of physical constants and general analytical methods, after which follow 95 pages on oils, fats and waxes, in which, logically perhaps but quite unexpectedly appear cocoa, chocolate, mercury ointment and "animal flour." After this are 89 pages on dairy products and six on eggs and egg products, including an awkward page on the use of egg albumin in baking powder, although that substance itself is not dealt with in the book. The remainder of the volume (109 pages) treats of the essential oils.

The book is primarily intended for the American worker, the official analytical processes, definitions, standards and limits being those of the U.S.P. and of the United States Department of Agriculture, and all the legal decisions are those of the "Federal notices of judgment."

The definition and standardisation of foods and drugs has been developed in America to an extent far beyond anything here, and the experience gained is certainly of value in this country, although hitherto the adoption of legally binding limits does not meet with universal approval. Amongst the substances dealt with in these pages, some are rarely, if ever, mentioned in our British text-books. Some because they do not reach our markets, and some perhaps because owing to our cumbrous laws or our outworn administration they are not readily amenable to legal control. Among these are "Crisco" and "Vegetole" (hydrogenated cottonseed oil products); "Natto" (a vegetable cheese): buttermilk tablets (a lactose inverting ferment): "Hamburgh steak" and homogenised dairy products. The oyster and its sophistications and the domestic egg and its substitutes have received special attention over there, even extending to what sounds like a work of supererogation—an "installation and equipment of an egg-breaking plant."

The general arrangement of the subject matter is unusual. Cocoa is dealt with under cacao butter, and dairy and egg products and flesh foods are sandwiched between the fatty and the essential oils.

The first four chapters on apparatus and methods are, as a whole, full and clear, but the treatment is somewhat unequal; the section on specific gravity, though interesting, contains too many references to semi-obsolete methods for a practical work, and yet is quite inadequate for a historical treatise.

The chapter on the polarimeter is on conventional lines, and along with most of our well-known text-books suffers by giving empirical directions which will be more easily followed than understood. Three pages devoted to figures for the optical rotation or

essential and fixed oils, alkaloids, etc., in this chapter are out of position, and in most cases are repeated over again under the appropriate headings in the main part of the book.

In spite of these slight defects in the arrangement of the subject matter, the actual utility of the book does not seriously suffer, as there is a very complete table of contents and the articles on individual substances are in alphabetical order.

An excellent feature is the bibliographical notes which include references to every modern original paper, from the chief English and American periodicals up to the end of 1921. They are most conveniently placed immediately after each article.

The writing is clear, terse and interesting, contains no serious misprints and, within the limits of the 400 odd pages, gives an excellent account of the various substances dealt with, and is liberally supplied with tables of physical constants and analytical data.

The type and general get-up are all that could be desired. CECIL H. CRIBB

MONOGRAPH ON CORROSION TESTS AND MATERIALS OF CONSTRUCTION FOR CHEMICAL ENGINEERING APPARATUS. *By* W. S. CALCOTT, J. C. WHETZEL, and H. F. WHITTAKER. *Published by the* AMERICAN INSTITUTE OF CHEMICAL ENGINEERS. *Pp.* vi + 182. *New York*: *D. Van Nostrand Co.*, 1923. *Price* \$3.

This monograph contains two papers, namely, (1) "Laboratory Corrosion Tests," by W. S. Calcott and J. C. Whetzel; (2) "Materials of Construction for Chemical Apparatus," by Harold F. Whittaker, together with discussions on the same. Both the authors and the American Institute of Chemical Engineers express their indebtedness to the du Pont Company for permission to publish the information, some of which has been gained through practical experience in the works, the remainder having been collected from general scientific literature. The hope is expressed that the example of this firm will stimulate others to release like information.

The first paper deals exclusively with laboratory tests, on various commercial metals, both ferrous and non-ferrous. As the object has been to determine which metals are most suitable for construction of plants to withstand the attack of chemicals the problem of atmospheric corrosion is not dealt with. The authors define, for the purpose of their report, the corrosion of a metal as "the reaction between the metal and another chemical compound by which a metallic product is formed which, possessing no mechanical strength, decreases the usefulness of the metal."

After discussing theoretically a number of factors which affect the rate of corrosion, accounts are given of different methods that have been tried in the laboratories with a view to determining the resistance offered by various substances towards such corrosive agents as mineral and organic acids, alkalis, aldehydes, complex dyes, etc. The paper contains a large amount of useful information not generally obtainable elsewhere, and the bibliography, which occupies some 18 pages, is a particularly valuable compilation.

The second paper deals with the subject from the point of view of practical experience. An engineer who wishes to construct a plant must not only consider the initial cost of the material, but the rate of corrosion as well, because replacement and repair costs may be so heavy with unsuitable materials as to render less corrodible, but more expensive, metals by far the cheapest in the long run. Amongst other things it is stated that aluminium is gradually replacing copper for the concentration of pure acetic acid, although copper still remains the most suitable material in the distillation of the crude acid, owing to the presence of formic acid which has a very destructive action on the aluminium. Numerous other facts of practical experience are given. The book makes most delightful reading and the Institute is to be congratulated upon its production.

J. NEWTON FRIEND

COMPTES RENDUS DU TROISIÈME CONGRÈS DE CHIMIE INDUSTRIELLE (PARIS, October 21-27, 1923) Pp. 1000. Paris: Société de Chimie Industrielle, 49, Rue des Mathurins. Subscription price, 50 francs.

The "Comptes-rendus" of the third Congress of Industrial Chemistry, held in Paris in 1923, have been edited by Monsieur Maurice Deschiens, and are being published by the Société de Chimie Industrielle. The volume opens with introductory chapters describing the organisation of the Congress, its division into groups and sections, the receptions and formal meetings, other work of the Congress, and visits to works and excursions. Then follow in extenso the important addresses given before the whole society by Prof. Menozzi, Prince Ginori Conti, and Sir John Russell, F.R.S.; the address of Prof. L. Lindet, having already been published, is not included. The complete texts of 130 communications, together with full discussions dealing with the most varied questions of chemical science and industry, and with economic organisation, occupy the remaining 800 pages of the volume.

DIE KERAMIK IM DIENSTE VON INDUSTRIE UND VOLKSWIRTSCHAFT. *By* FELIX SINGER, D.Eng., Ph.D. *Brunswick*: *Fr. Vieweg & Sohn, A.-G.*, 1924. *Price* 50*s*.

Dr. Singer has adopted an exceedingly interesting means of celebrating the Jubilee of the very large firm of pottery manufacturers with which he is connected, inasmuch as he has asked all the leading authorities on clay and clay products to contribute to a volume on "Ceramics in Industry and National Economy." The result is a volume of well over a thousand pages, containing contributions from more than ninety contributors. Each section is written by an expert and can, therefore, be relied upon as authoritative.

The whole field of ceramics is well covered in an interesting as well as accurate manner and with that meticulous attention to detail which is characteristic of the best technical literature in Germany.

There is no book of the same character in the English language, the nearest being Bourry's "Treatise on Ceramic Industries," which is both older and much smaller. This is not due to any lack of knowledge on the part of English ceramists, but to the preference in this country for more highly specialised monographs dealing with a single part of the industry instead of with ceramics as a whole. At the same time, there ought to be a demand for a good book of this type in the English language to which students can refer.

The scientific part of this volume is well written, but there is a regrettable lack of reference to English ceramists, though American ones are more frequently mentioned by name. The English names are frequently quoted with reference to relatively unimportant matters, so that no reader of the book would have any idea of the extremely valuable work done in this country.

It is stated that the chemical constitution of clays is undeterminable and that no accurate method for determining plasticity has yet been discovered. In this and in other ways, it is clear that German ceramists are in no way more advanced than our own, though by greater attention to detail and by having greater facilities of scientific control in the works, some of them are able to produce some articles of better quality.

A. B. SEARLE

DIE PHYSIKALISCHEN UND CHEMISCHEN GRUNDLAGEN DES EISENHÜTTENWESENS. By WALTHER MATHESIUS. Second revised edition. Pp. xviii + 483. Leipzig: O. Spamer, 1924. Price, bound, 30 goldmarks, paper, 27 gm.

The general scheme of this book is a decidedly attractive one. The object of the author has been to place in the hands of those engaged in the manufacture of iron and steel a work in which the physical and chemical principles upon which their operations must be based are clearly set forth. Having regard to the knowledge to be presumed in his readers, the author has set out to deal mainly with the chemical processes and to avoid any description of the construction of the plant employed in the various operations except where this might be indispensable for a clear understanding of the chemical operations, and he has carried out his scheme with the sole exception that he has described and figured the various types of electrical smelting furnaces; it is not in the least clear why he should have made an exception in their favour.

The first portion comprises physical and chemical laws and data, and contains chapters upon oxidation and reduction, combustion and the development of heat, and the principal fuels used for this purpose. Here is included the chapter upon electric furnaces above referred to, and the other chapters deal with the heat of fusion, of evaporation and solution, and also with the specific heat of the various substances. The chemistry of iron, as far as it enters into the ordinary operations of its metallurgy, is next considered, and the combinations of iron with carbon, silicon, phosphorus, sulphur, and the various alloys of iron complete the chapter. The next part consists of a review of the fuels in general use, namely, coal, wood, coke, liquid and gaseous fuels and the various methods of applying these. The third section deals with the production of pig iron and includes chapters upon the available ores and materials, upon slags, the calculation of the furnace charge, the theory of the blast furnace and thermal balance of the blast furnace, in which the author considers separately thermal balances in the shaft and in the boshes. A few notes on special modifications conclude this section. The fourth section covers the manufacture of ingot iron and deals with the Bessemer process, the basic process and the open-hearth process, together with modifications of the last named. The various chemical processes involved are considered in some detail. The fifth section is devoted to iron and steel foundry practice, and certain detailed calculations are given in the Appendix.

It will be seen that the general idea underlying the work is an exceedingly good one. In order, however, that such a book may be really useful, it is necessary that it should be up to date and accurate, and in both respects it must be admitted that the present work fails hopelessly. As regards the former, the first edition of the work was published in 1915, and the author appears to have commenced a revision of the second edition in 1922. In order to show how utterly imperfect that revision has been, it may be sufficient to quote one sentence which refers to "the most important iron ore deposit of Germany, the Minette of Luxemburg-Lorraine"; surely in 1924 Prof. Mathesius must have known that the iron ore deposits of Lorraine had returned to their rightful owners! Throughout the author evinces a most lamentable ignorance of British literature; it may sound incredible, but it is a fact that there is hardly one reference to the Journal of the Iron and Steel Institute and not a single modern one. It can hardly be supposed that the author is ignorant of the existence of this journal or that he could not have known that he would find therein modern information in which he is painfully behind the times. It is impossible to cite all the passages in which this deficiency is made manifest, but some of them are sufficiently startling. For instance, we find such a sentence as the following: "Approximately from the year 1900 onwards the description of coaldust firing has disappeared from technical literature, and to-day the application of this method of firing is almost exclusively confined to the heating of rotating cylindrical furnaces, the great majority of which are used in the manufacture of cement." No one who has any acquaintance with the modern technology or the modern literature of fuel can fail to be aware that coal dust firing has received most important developments within the last few years. Again, the author devotes a few lines to the allotropism of iron and states baldly that pure iron possesses three different modifications, known as α iron, β iron and γ iron, and thus absolutely ignores the important work of Prof. C. Benedicks and his theory that the so-called β modi-

fication of iron is really α iron containing a certain amount of γ iron in solution. This theory is a dozen years old and has found numerous adherents among the leading authorities, so that it is hardly one to be passed over absolutely without reference in a textbook with any pretension to accuracy or completeness.

The author gives an elaborate graphic method for calculating the heat balance of the blast furnace and insists upon treating the shafts and the boshes as separate entities: he applied this method to the discussion of the working of a furnace of the Wisconsin Steel Company in 1915, as described by Mr. H. P. Howland (Trans. Amer. Inst. Min. Eng., vol. LVI., 1916, page 339); Prof. J. W. Richards in the subsequent discussion characterised it as "rather involved and strained reasoning," which not inaptly describes the method in question. If Prof. Mathesius had taken the trouble to consult a paper by Mr. F. Clements on "British Blast Furnace Practice" in the Journal of the Iron and Steel Institute for 1920, vol CI., page 325, he would have found a far more satisfactory method of calculating thermal balances. Again, he could with much advantage consult a subsequent paper (1922) by the same author on "British Siemens Furnace Practice," a study of which would greatly improve his chapter upon the open-hearth process. It is, by the way, somewhat incomprehensible why the author should insist upon looking upon the ore process as a mere modification of the Martin pig and scrap process, seeing that it was evolved quite independently and that although the modern open-hearth process is a combination of both, it is really based far more upon the work of Dr. Siemens than of Messrs. Martin.

It is perhaps unnecessary to discuss the book in any further detail; it might have been a good book twenty years ago; it is hopelessly out of date to-day. It is also regrettable that the work is disfigured by very numerous misprints. Altogether a thoroughly disappointing book. H. Louis

Solubility. By Joel H. Hildebrand. American Chemical Society Monograph Series. Pp. 206. New York: The Chemical Catalogue Co., 1924. Price $3.

Since Rothmund's book many years ago little of a systematic nature has been published on the subject of solubility as a phenomenon possessing a physico-chemical mechanism.

The spirit of Hildebrand's book is shown by the Preface, which manifests a liberal and philosophic mind. The author, as becomes one who resides at Berkeley, Calif., is evidently permeated by the concept of fugacity and its allied functions. An important aspect of the work, in fact, is the exposition of the rôle which such thermo-dynamic quantities play in solution and solubility problems. "Our fundamental problem, therefore, is to determine so far as possible how the escaping tendencies of the various components of a solution may be expected to vary, first with the composition of the solution, and second with the nature of the components. It is evident that this is a problem of great importance, both from the theoretical and the practical standpoints, and that much of modern physical chemistry is concerned with it." For the sake of brevity the author assumes considerable familiarity with the well-known book of G. N. Lewis and Randall; and as most physical chemists are, or ought to be, familiar at least generally with this work, the method adopted by Hildebrand is commendable.

The general nature and scope of the book will be gathered from the following, which is an abbreviated list of chapter headings: The ideal solution—Raoult's law; deviations from Raoult's law and their causes; polarity, internal pressure, and solvation; vapour pressure of liquid mixtures; solubility of gases, of liquids, of solid non-electrolytes, and of electrolytes; partition of solutes between immiscible liquids; metallic solutions; solubility and various related phenomena.

A perusal of this work impresses one very much with the advances which have been made within recent years in our understanding of the factors which govern solubility and the nature of the resulting systems. From a record of empirical fact there is gradually emerging a coherent body of concepts and generalisations. Naturally, the development has been very unequal along various directions, certain aspects being represented by little more than qualitative speculation. That the problem as a whole is still far from being understood is evident from the following quotation (p. 117): "The prediction of chemical combination is (however) the main goal of chemistry, and until it is reached the problem of solubility will likewise remain more or less unsolved."

The editors of the American Chemical Society Monograph Series have been particularly fortunate in certain of their contributors, and in none more so than in the present instance. W. C. M. Lewis

Pflanzenuntersuchungen, Handbuch der biologischen Arbeitsmethoden. Abt. XI. Part 2. No. 4. Edited by Prof. E. Abderhalden. Pp. 656-764. Berlin: Urban & Schwarzenberg, 1924. Price 5.25. s.f.

The part under review forms the 121st of the well-known Handbook published under the general editorship of Prof. E. Abderhalden and contains two essays—one entitled "Methoden der Viskositätsbestimmungen des lebenden Protoplasmas" and the other "Methoden zur Feststellung der Keimfähigkeit von Pflanzensamen" contributed respectively by Friedl Weber and Karl Müller. In the former the methods of determining the viscosity of living protoplasm are described under two headings—those designed for more or less accurate measurement and those intended to give approximate estimates only of the viscosity. Under the first are described methods based upon an adaptation of the falling sphere viscosimeter, in which the rate of movement of particles in protoplasm is determined under either centrifugal or gravitational force, or else the movement of small particles of iron introduced into the cell from without is measured when in a magnetic field. For the approximate estimation of viscosity the author describes in detail

the methods and apparatus of Kite and Chambers for micro-dissection; employing these methods the protoplasm can be pricked, kneaded, teased and drawn out into threads, etc., and the results are compared with those obtained under similar conditions from gelatin solutions of various known concentrations; other methods include those based upon observations of kataphoresis, Brownian movement, and plasmolysis. A perusal of this essay will convince the reader of the difficulty inherent in the determinations and the ingenuity of the methods employed.

In the second essay, dealing with the germinating power of seeds, the author begins by describing in detail the effect of various factors, such as oxygen, heat, cold, water and light upon germination and then proceeds to an account of the methods, media, and apparatus employed in experiments on germination, together with suggestions for the design of a germinating chamber. The article concludes with an alphabetical list of a number of common seeds in which are given, in tabular form, particulars of media, temperature and other details to be observed in determining germinating power in accordance with the technical instructions laid down by the German Verband landwirtschaftlicher Versuchsstationen. Those interested in the important subject of seed germination will find here a useful summary of the more important methods employed in the investigation of the subject.

P. Haas

Die Technische Chloralkali-Elektrolyse. By Dr. J. Billiter. Pp. viii+79. Dresden and Leipzig: Theodor Steinkopff, 1924. Price, 2·50 gold marks.

This little volume is the second in a series of monographs which is being published by Th. Steinkopff on recent advances in technical processes. Within the scope of about 80 pages the manufacture by electrolysis, of caustic soda, sodium carbonate and chlorine, hypochlorite, chlorate and perchlorate are described. About half of this is devoted to the description of alkali processes which employ solid (non-mercury) cathodes, another 14 pages being reserved for the advances that have been made in this branch during the last ten years. The book is well arranged. It gives a good survey of the whole field covered, and is clearly written and illustrated where necessary. Statistics are given, in most cases showing the extent to which the several processes are employed, as revealed by the horsepower used. Obsolete methods are not described. The very great extension which the solid-cathode processes for caustic soda have experienced in recent years will perhaps come as a surprise to many. The book will be useful, not only to students, but also to those engaged in the chemical industry who wish to obtain a clear idea of the advantages and difficulties inherent in the several methods of manufacture. Coming as it does from the pen of one who has himself contributed so conspicuously to the advancement of the subject described it should find a wide circle of readers.

Henry J. S. Sand

COMPANY NEWS

THE SALAR DEL CARMEN NITRATE SYNDICATE, LTD.

In presenting the Report and Accounts of the Salar del Carmen Nitrate Syndicate, Ltd., the chairman said that their net profit during the year ended December 31 last amounted to £78,053, and adding this to £16,218 brought forward from the previous year, there was a total credit on profit and loss account of £94,271. The directors proposed to set aside £20,000 to reserve account and to apply £7039 to reduction of plant and machinery account. It was recommended to pay a final dividend of 25 per cent. less tax, making the total distribution for the year 30 per cent., compared with 25 per cent. in respect of the year 1922. The amount carried forward was £16,949.

Considering the unsettled economic conditions which existed throughout the greater part of the world, the chairman thought that the position of nitrate was encouraging, the total consumption of nitrate during the year ended June 30, 1924, being estimated at about 2,180,000 tons, an increase of 30,000 t. on the previous year.

In Norway, owing to strikes, the manufacturers of nitrate of lime who had sold ahead, had been unable to deliver about 25,000 t. in time for the season's use, and an increase in Chilean nitrate business had consequently taken place in Scandinavia. In France the Government had voted a substantial sum of money for the exploitation of the Haber process, the rights for which were purchased from Germany some time ago, but the plant was not expected to be ready for two or three years. In the United Kingdom, at Billingham, the Brunner Mond plant had almost reached the production stage. The chairman finally referred to the Nitrate Producers' Association, formed in 1919, and due to terminate at June 30 next. Negotiations were, however, proceeding with a view to the renewing of the Association for a further period of six years, on the understanding that at the end of the first three years members of the Association may, if they wish, revert to free selling of nitrate. Already producers, representing 92½ per cent. of the total productive capacity, had voted in favour of renewing on these terms.

The meeting closed with the re-election of the Rt. Hon. Lord Forres and Mr. A. Naylor as directors of the company.

BRITISH COTTON AND WOOL DYERS' ASSOCIATION

The report of the above company for the year to March 31, 1924, shows a net profit of £150,233, as compared with £176,547 for the previous year. The amount brought forward was £37,132, making available £187,365. A dividend of 10 per cent. on the ordinary shares is proposed, as against 15 per cent. last year. The amount to be transferred to reserve is £50,000 (making that fund £81,459); £5,000 is to be placed to investment contingency fund (bringing that fund to £35,000); £10,000 to employees' benefit fund (£20,000 last year), and the sum of £44,949 has been carried forward.

SOCIETY OF CHEMICAL INDUSTRY IN BASLE

The directors of the above company state in their report that facilities for the export of their products have not improved, especially as regards England and the United States. The high restrictions and tariffs in force in these countries, although they do not prevent the sale of the company's goods, make business very difficult, and they were of the opinion that these highly protective measures would have to be modified. An improvement was shown during the year as regards sales in general, especially in the Far East, and this improvement is also continuing in the present year

EASTMAN KODAK CO.

This American company announces a regular dividend of $1\frac{1}{2}$ per cent on Preferred stock; a regular dividend of $1 25 per share on common stock; and an extra dividend of $0.75 per share (the same) on the common stock, all payable on July 1.

NITRATE PRODUCERS' ASSOCIATION

The Chilean Nitrate Committee announces that the above Association has been renewed from July 1 for a period of 6 years Prices of nitrate per metric quintal have been fixed at figures ranging from 19s. 3d. for delivery in July, to 20s. 9d. for delivery between January 1, 1925, to May 31, 1925. It is expected that the average price will show a reduction of about 7d. per metric quintal.

BRANDRAM-HENDERSON, LTD.

The annual financial statement of Brandram-Henderson, Ltd., for the financial year 1923 has been submitted. It shows an increase in sales of over 10 per cent. with net profits at $144 121, which is somewhat lower than last year with $163,703. The reason for this falling off in profits is attributable to the fact that the Alberta Linseed Oil Co., Ltd., a subsidiary, did not pay a dividend during the period, as the company had been called upon to pay a large amount of Federal Government income taxes retroactive for some years. The profit and loss account shows a balance of $854,585 brought forward from 1922, from which was deducted the preferred dividend of $35,000 and the common dividend of $47,196, leaving $772,389. To this amount was added the profits, after deducting usual charges, making a total of $916,511. Against this amount are debits for bond interest paid and accrued $63,460; reserve for depreciation $7,500; income tax 1922, $9,621; leaving a surplus to carry forward of $836,929.33. The balance sheet shows several changes, fixed asset are up $2,713,131.45 to $2,735,723.54, being in the plant account, the depreciation reserve is now increased to $95,000. Fixed liabilities and bonded statement shows bonds outstanding at $898,000. Working capital account shows considerable improvement over the past three years, increasing from $981,175 in 1921 steadily to $1,156,985 in 1923. A dividend of 7 per cent. has been declared on the preferred stock, and 4 per cent. on the common.

REPORT

Report on the Trade, Industries and Economic Conditions in Portugal, January, 1924. By S. G. Irving, H.M. Consul and Commercial Secretary, Lisbon. Department of Overseas Trade. Pp. 44. H.M. Stationery Office, 1924, Price 1s. 6d.

The financial situation in Portugal is still unsettled, but the low value of the escudo is not an indication of impoverishment of the country, which is at present in a prosperous condition, with little unemployment. The fluctuating rate of exchange has complicated commerce abroad, but purchases have been made from Great Britain under the credit scheme initiated in 1922, and Portugal takes a good position among the smaller European countries as an importer from this country. Great Britain is the largest buyer of Portuguese goods.

The war had the same effect on trade in Portugal as in other belligerent countries; 1919 and 1920 saw a boom period which gave way to a slump which has lasted till now. The bulk of imports into the country consists of foodstuffs, coal, oil, and manufactured goods. Imports in 1923 of petroleum products, which formed the most valuable item of imports were fuel oil, 63,665 t.; benzine, 28,920 t.; kerosene 26,400 t.; mineral oil, 7720 t.; paraffin, 1595 t. Coal imports in 1923 were 766,000 t.; valued at £1,004,600; this is supplied almost entirely by Great Britain, which is also the chief supplier of textiles. The iron and steel goods chiefly in demand from Britain are black and galvanised plates, tinplate, bars, tubes and wire; manufactured copper is obtained chiefly in Great Britain. Among heavy chemicals copper sulphate, ammonium sulphate caustic soda, and sodium silicate are largely imported from Great Britain; Germany and Belgium compete in these lines. Sulphur is obtained chiefly from Italy and the United States.

The principal exports from the country are wines, sardines, pit props, cork, textiles, fruit, copper, salt, and wolfram. About 180,000 t. of copper was exported last year, mostly from the British mine at S. Domingo.

In spite of recent troubles over payment British traders are advised not to abandon the market, business is there for those who seek it, and importers are advised to make a first-hand study of the market, taking care to appoint suitable agents and to accept only reliable clients.

The principal manufacturing industries of the country are textile, but other factories are established items of importance being cement, tiles, pottery and glass. But little mining is done in the country There is believed to be an abundance of good coal and anthracite is found in Central Portugal. From the vast deposits of iron ore only 30,000 t. is drawn annually. Water power is available in sufficient quantity to enable the imports of fuels to be considerably reduced, but insufficient capital is available to make any progress in the development of schemes which have been drawn up.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	43s. 6d. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	5s. 1d. per lb. Much dearer, following rise in quicksilver.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s.—5s. 3d. per gall. 60% O.P. market stiffer.
Solvent	5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£49 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7d. per lb. Better inquiry at reduced price.
Crude 60's	1s. 10d.—2s. per gall. Market rather flat.
Acid Cresylic, 97/99	2s. 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Pure	1s. 10d.—1s. 11d. per gall.

Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9½d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	7½d.—9d. per gall. according to grade and district. Market a shade firmer. Fair business.
Naphtha—	
Crude	8d.—9d. per gall. } Good demand. Prices firm.
Solvent 90/160	1s. 5d.—1s. 7d. } Good demand. Prices firm.
Solvent 90/190	1s. 2d.—1s. 3d. } Good demand. Prices firm.
Naphthalene Crude—	
Drained Creosote Salts	£7—£7 10s. Steady business.
Whizzed or hot pressed	£9—£12 per ton. Not much inquiry.
Naphthalene—	
Crystals and Flaked	£17—£18 per ton.
Pitch, medium soft	52s. 6d.—57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt
Pyridine 90/140	22s.—24s. per gall. Demand well maintained.
Heavy	11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 3d. per lb. Steady demand.
Acid Sulphanilic	10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethyaniline	2s. 5d per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene —48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 1d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£49 per ton.
Acid, Acetyl Salicylic	3s. 4d.—3s. 5d. per lb. Good demand.
Acid, Benzoic B.P.	3s. 3d.—4s. per lb. Larger supplies available.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst.	7s. per lb. for 1 cwt. lots. Market firm: increasing demand.
Acid, Salicylic	Prices quoted from 2s. 2d. per lb. down to 1s. 9d. for ton lots. Market rather quiet.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Easier market.
Amidopyrin	13s. 6d. per lb. Neglected.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market easier.
Potassium	9d.—10½d. per lb.
Sodium	9d.—10½d. „
Ammonium	10½d.—1s. „
Calcium Lactate	Demand not very active. Good English make can be had from 1s. 7d. to 2s. per lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots. Market more active. Makers busy.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	12s. per lb. for cwt. lots. Supplies not plentiful.
Hexamine	3s. 9d. per lb. for foreign make. Fairly steady.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 9d. per lb. Foreign make.
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate— Light Commercial	£36 per ton net.

Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 70s. per lb.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials ..	.. Market rather flat, but prices unchanged.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. ,,
White precip. ..	.. 4s. 7d.—4s. 8d. ,,
Calomel ..	.. 3s. 11d.—4s. ,,
Methyl Salicylate	.. 2s. 3d.—2s. 9d. per lb. for carboys. A slightly better market.
Methyl Sulphonal	.. 25s. per lb.
Paraformaldehyde	.. 3s. 6d. per lb.. Better inquiry.
Paraldehyde ..	.. 1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin ..	.. 6s. per lb. Somewhat cheaper.
Phenazone ..	.. 7s. 9d. per lb. for cwt. lots. Quiet.
Phenolphthalein ..	.. 6s. 9d.—7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate—	
99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 8d.—2s. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal ..	.. 8¾d.—9d. per lb. carriage paid.
Commercial ..	.. 8d.—8½d. per lb. carriage paid.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 6d. per lb.
Salol	.. 4s. per lb. Very quiet.
Silver proteinate	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 3s. per lb. In steady demand for good qualities.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—	
Photographic ..	.. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet
Sod. Salicylate ..	.. Market easier. Powder 2s. 4d.—2s. 6d. per lb. Crystal at 2s. 6d.—2s. 8d. per lb. Flake 2s. 9d.—3s. 4d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	.. 16s.—18s. per lb.
Tartar Emetic	.. 1s. 4d. per lb.
Thymol	.. 13s. 6d.—15s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.	
Aubepine	.. 14s. 6d. per lb.	Advanced.
Amyl Acetate ..	.. 2s. 9d. ,,	
Amyl Butyrate ..	.. 7s. 3d. ,,	
Amyl Salicylate ..	.. 3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d. ,,	
Benzaldehyde free from Chlorine ..	.. 3s. 6d. ,,	
Benzyl Benzoate	.. 3s. 6d ,,	
Cinnamic Aldehyde Natural	.. 15s. 6d. ,,	
Coumarin ..	.. 20s. ,,	
Citronellol ..	.. 16s. ,,	
Citral	.. 10s. ,,	
Ethyl Cinnamate	.. 15s. ,,	
Ethyl Phthalate ..	.. 3s. 9d. ,,	
Eugenol	.. 11s. ,,	
Geraniol (Palmarosa)	.. 35s. ,,	
Geraniol	.. 11s.—18s. 6d. per lb.	
Heliotropine ..	.. 7s. 9d. per lb.	
Iso Eugenol ..	.. 15s. 9d. ,,	
Linalol ex Bois de Rose ..	32s. 6d. ,,	
Linalyl Acetate ..	.. 32s. 6d. ,,	
Methyl Anthranilate	.. 9s. 6d. ,,	
Methyl Benzoate	.. 6s. ,,	
Musk Ambrette ..	.. 52s. 6d. ,,	
Musk Xylol ..	.. 18s. ,,	
Nerolin	.. 4s. ,,	
Phenyl Ethyl Acetate	.. 12s. 6d. ,,	
Phenyl Ethyl Alcohol	.. 16s. ,,	
Rhodinol	.. 57s. 6d. ,,	
Safrol	.. 1s 10d. ,,	
Terpineol	.. 2s. 9d. ,,	
Vanillin	.. 25s. 3d.—26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 15s. 6d. per lb.	
Anise Oil	.. 3s. per lb.	
Bergamot Oil ..	.. 18s. 6d. per lb.	
Bourbon Geranium Oil	.. 35s. ,,	
Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil, Java	.. 10s. 6d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Cassia Oil, 80/85%	.. 9s. 3d. per lb.	
Citronella Oil—		
Java 85/90% ..	.. 5s. 6d. per lb.	Dearer.
Ceylon	.. 3s. 9d. ,,	
Clove Oil	.. 8s. 3d. ,,	
Eucalyptus Oil 70/75% ..	2s. 2d. ,,	
Lavender Oil—		
French 38/40% Esters	26s. per lb.	
Lemon Oil ..	.. 3s. 2d. per lb.	Cheaper.
Lemongrass Oil ..	.. 3d. per oz.	
Orange Oil, Sweet	.. 13s. 9d. per lb.	
Otto of Rose Oil—		
Bulgarian ..	.. 27s. 6d. per oz.	
Anatolian ..	.. 23s. 6d. per oz.	
Palma Rosa Oil ..	.. 19s. per lb.	Very short supply.
Peppermint Oil—		
Wayne County	.. 21s. 9d. per lb.	
Japanese ..	.. 18s. 3d. per lb.	
Petitgrain Oil ..	.. 10s. per lb.	
Sandal Wood Oil—		
Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 7th. they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on May 22nd.

I.—Applications

Baglin. Centrifugal dryers. 10,815. May 2.

Bell. Disintegrating and mixing. 10,651. Apr. 30.

Borrmann. Distillation. 10,883, 10,884. May 2.

Brandwood and Price. Grinding or granulating machines. 10,729. May 1.

Ges. für Linde's Eismaschinen Akt.-Ges. Method of cooling and condensing gaseous mixtures. 10,664. Apr. 30. (Ger., 31.5.23.)

Grimm. Process for stabilising various materials. 10,890. May 2.

Kent and Sykes. Furnaces. 10,962. May 3.

Patentaktiebolaget Grondal-Ramén. Rotary etc. furnaces. 10,972. May 3. (Sweden, 12.5.23.)

Portes. Mixing liquids of different temperatures etc. 10,878. May 2. (Fr., 29.5.23.)

Sonsthagen. Mixing, compacting, and degassing viscid materials. 10,659. Apr. 30.

Velut. Filtering devices 10,847. May 2. (Fr., 12.5.23.)

I.—Complete Specifications Accepted

3388 (1923). Appareils et Evaporateurs Kestner. Apparatus for distilling water (208,503.)

8514 (1923) Volcker. Furnaces. (214,808.)

11,475 (1923). Senior and Atkinson Drying-machine. (214,830.)

II.—Applications

British and Foreign Lime and Power Corporation, Ltd., and Reid. Manufacture of gaseous fuel from lime-kiln gases. 10,989. May 3.

Donald. Peats etc. 10,955. May 3.

Fairbairn. Apparatus for sweating or crystallising paraffin etc. wax. 10,467. Apr. 28.

Farbwerke vorm. Meister, Lucius, und Brüning. Process of making methane. 10,794. May 1. (Ger., 1.5.23.)

Jolly. Carbonisation of bituminous caking coals 10,746. May 1.

Mureosche. Manufacture of agglomerated combustibles. 10,742. May 1.

II.—Complete Specifications Accepted

29,384 (1922). Neilsen, Laing, and Boocock. Manufacture of fuel briquettes. (214,668.)

34,052 (1922). Hellmann. Dry-distillation, de-gasification, or gasification. (214,675.)

1222 (1923). Algem. Norit Maatsch. Producing activated carbon. (198,328.)

2543 (1923). Anglo-Saxon Petroleum Co. (Hillman). Purifying mineral oils from sulphur. (214,733.)

14,368 (1923). Rutgerswerke Akt.-Ges. Production of arc-light electrodes. (199,018.)

16,162 (1923) V. L. Oil Processes, Ltd., and Lucas. Treatment of oils and spirits. (214,871.)

28,620 (1923) Algem Norit Maatsch. Producing activated carbon. (206,862.)

IV.—Applications

Durand and Huguenin Akt.-Ges Manufacture of disazo-dyestuffs. 10,882. May 2 (Ger., 2.5.23.)

Farbwerke vorm Meister, Lucius, und Brüning. Manufacture of halogenated oxythionaphthenes 10,479. Apr. 28. (Ger., 28.4.23.)

Scottish Dyes, Ltd., Smith, and Thomas. Dyestuffs and dyeing. 10,886. May 2.

IV.—Complete Specifications Accepted

3584 (1923). British Dyestuffs Corporation, Ltd., Perkin, and Clemo. Manufacture of bodies related to the acridines. (214,756.)

3828 (1923). Drescher, Thomas, and Scottish Dyes, Ltd Production of anthraquinone bodies. (214,765.)

15,071 (1923). Imray. (Soc. of Chem. Industry in Basle) Manufacture of indigoid dyestuffs. (214,864.)

V.—Applications

Dreaper. Manufacture of artificial silk. 10,849. May 2

Klugmann. 10,951. *See* X.

V.—Complete Specification Accepted

17,790 (1923). Wuensch and Köppel. Extracting from vegetable substances products for use in making paper etc. (214,882.)

VI.—Applications

Farbenfabriken vorm. F. Bayer und Co. Dyeing acetate silk. 10,791. May 1. (Ger., 1.5.23.)

Scottish Dyes, Ltd., Smith, and Thomas. 10,886. *See* IV.

VII.—Applications

British and Foreign Lime and Power Corporation, Ltd., and Reid. 10,989. *See* II.

Friedenthal, and Industrie-Verwaltung A.-G. Bromine solutions. 10,444. Apr. 28. (Ger., 27.4.23.)

Hooper. Applying deposits etc. of silicon etc. to surfaces. 10,958. May 3.

VII.—Complete Specifications Accepted

1775 (1923). Bhopal Produce Trust, Ltd., and Fraymouth. Obtaining oxalic acid or its salts. (207,489.)

2052 (1923). Bhopal Produce Trust, Ltd., and Fraymouth. Obtaining calcium oxalate from vegetable matter. (208,684.)

VIII.—Complete Specification Accepted

1697 (1923). Holden. Removal of the brown coloration in china clays. (211,699.)

IX.—Applications

British and Foreign Lime and Power Corporation, Ltd., and Reid. 10,989. *See* II.

Pioda. Manufacture of Portland cement. 10,556. Apr. 29. (U.S., 4.5.23.)

Tomlins. Building materials. 10,573. Apr. 29.

Zuttere. Impregnating woods. 10,793. May 1

IX.—Complete Specification Accepted

5423 (1923). Babcock and Wilcox, Ltd. (Babcock and Wilcox Co.). Cement-kiln systems. (214,779.)

X.—Applications

Beasley, Middleton, and Metals Production, Ltd. Reduction of ores. 10,805 May 1.

Garnett and Smith. Magnetic alloys etc. 10,977. May 3.

Hooper. 10,958. *See* VII.

Klugmann. Manufacture of cotton corduroy cloth for extraction of gold. 10,951. May 3.

Simon. Concentration of tin ores. 10,635, 10,636 Apr. 30.

Soellner Nachf. Reisszeugfabrik Akt.-Ges. Production of a weatherproof oxide layer on electron metal. 10,600 Apr. 29. (Ger., 1.7.23.)

Vanderstein. Cupola furnaces. 10,779. May 1.

Wittig. Method of making iron alloys. 10,567. Apr. 29. (Ger., 12.7.23.)

Wittig. Method of extracting vanadium. 10,699. Apr 30. (Ger., 7.5.23.)

X.—Complete Specification Accepted

13,755 (1923). Titanium Pigment Co. Treatment of titaniferous material. (206,809.)

XI.—Applications

Soc. Talco e Grafite val Chisone, and Ridoni. Manufacture of electrodes from natural graphites. 10,450 Apr. 28.

Stuart. Electrolytic cells. 10,551. Apr. 29. (U.S., 30.4.23.)

XI.—Complete Specifications Accepted

7762 (1923). Monnot. Electric storage batteries. (214,799.)

10,359 (1923). Helfenstein. Forming continuous electrodes for electric furnaces. (214,823.)

14,368 (1923). Rütgerswerke Akt.-Ges. *See* II.

26,140 (1923). Soc. Anon. le Carbone. Rendering porous electrodes impermeable to liquids. (211,832.)

XII.—Complete Specifications Accepted

34,885 (192). Petroff. Production of soap. (214,679.)

2591 (1923). Aische. Manufacture of solvent soaps from sulphonated oils. (214,735.)

XIII.—Application

Potter (Soc. Anon. L'Oyonaxienne). Manufacture of plastic material. 10,413. Apr. 28.

XIII.—Complete Specification Accepted

13,755 (1923). Titanium Pigment Co. *See* X.

XV.—Application

Long. Treatment of vegetable ivory. 10,705. Apr. 30.

XVI.—Application

Telfer. Fertiliser. 10,974. May 3.

XIX.—Application

Chapman. Treatment of frozen meat. 10,587. Apr. 29

XIX.—Complete Specifications Accepted

3388 (1923). Appareils et Evaporateurs Kestner. *See* I.

10,342 (1923). Bull. Insecticides, vermifuges, sheep-dips, and the like. (214,822.)

XX.—Application

Johnson (Badische Anilin und Soda-Fabrik). Process for transforming oxides of carbon into organic compounds. 10,435. Apl. 28.

XX.—Complete Specifications Accepted

11,971 (1923). Rausford (Cassella u. Co.). Manufacture of *p*-dialkylaminoarylphosphinous acids. (214,836.)

15,324 (1923). Howards and Sons, Ltd., and Blagden. Manufacture of benzene derivatives containing carbon side-chains, particularly thymol. (214,866.)

17,256 (1923). N. V. Vereen. Fabr van Chemische Producten. Obtaining organic super-oxides in a finely divided condition. (200,508.)

27,340 (1923) Merck, Wolfes, and Maeder. Manufacture of synthetic *l*-cocaine (214,917.)

XXI.—Complete Specification Accepted

9530 (1923). Pathé Cinema. Obtaining direct photographic positives by reversal. (211,431.)

XXIII.—Complete Specification Accepted

2104 (1923). Hilger, Ltd., and Ord. Polarimetric apparatus (214,712.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1.) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number: *Argentina*: Scientific and optical instruments, glassware, (21722/F.W./C.C./2); *Australia*: Artificial silk yarns, (497); Electrical machinery, (499); *British West Indies*: Mining supplies, (501); *Canada*: Builders' hardware, cutlery, crockery, (502); *Cochin-China*: Iron and steel hollow-ware, (853/9/F.G./E.C./2); *Esthonia*: Sugar, (508); *France*: Sulphate of copper, (509); Italy: Silk, (511); *Netherlands*: China, earthenware, glassware, (514); Silk, (516); Paint, chemicals, pharmaceutical specialities, surgical rubber goods, (517); Hardware, crockery, paper, (519); Cement and bitumen roofing, (22816/F.W./M.C./2); *Poland*: Photographic materials, (521); *Smyrna*: Skins, hides, tinplate, iron (525); Agricultural machinery, (12883/F.E./E.C./2); *South Africa*: Cutlery, (505); Linseed oil, (13613/E.D./C.C./2): Varnish and enamel (529); *Switzerland*: Galvanised and black sheets and tubes, (524); *United States*: Perfume, (529).

Trade Information

The H.R. Gear is a most interesting device the object of which is to provide, in a compact space, means for increasing or decreasing the speed between a prime mover and a working object. Although involving no new engineering principle, the gear constitutes undoubtedly a new application of the worm gear, of which it retains both the efficiency and the strength but in enhanced form, the efficiency having been found to be 75 per cent. in one case, compared with 50 per cent. for an ordinary worm gear. Any gear ratio from 1 to 1 upwards to 10,000 to 1 or very much more can be obtained in a small space, as the system allows of an almost infinite variety of speed ratios with little change of the actual gear. In addition it presents various interesting advantages, such as the possibility of obtaining from one gear more than one source of drive, each source furnishing power simultaneously at different speeds and at different angles from the prime mover, as for instance two separate conveyor belts at right angles. In addition the gear can furnish one source of drive, the speed of which can be varied in steps as required, *e.g.*, in a mechanical stoker. As a further instance of its adaptability the gear can be mounted for use in a lifting drum. Ordinary gears are rarely free from "chatter," but the H.R. gear is noiseless and, as it works in an oil bath, it should have a long life. The largest gear yet made is that for the Bleachers' Association, being designed to deal with 150 h.p. at the very slow speed of 9·6 revolutions per minute. The smallest gear is for one-fiftieth of a horse-power. A number of H.R. gears can be seen at the British Empire Exhibition at Wembley.

Metallisation is the name given to a process by means of which any solid can be coated with an impervious layer of any of the useful metals or alloys. Zinc, tin, lead, aluminium, copper, iron, nickel, brass, bronze and other metals or alloys can be deposited by the process in layers of any thickness from 0·001 in upwards. In a general manner, metallisation can be said to be useful for the prevention of corrosion, for the production of an artistic effect, or for improving the appearance of manufactured articles. No vehicle is used in depositing the metal, which never cracks or chips off, and it is deposited in such a cool state that fabrics are uninjured and thin metallic articles are not warped in any way. The metal coating can be left in a matt state, and can then be painted or lacquered, or it can be coloured and polished. Applications of metallisation that are of particular interest to

the chemical industry, are the coating, externally and internally, of iron and steel structures, tanks, vats, pipes, and mixers with metals such as lead, aluminium, tin, copper, etc., to prevent corrosion by specific acids, vapours and gases. For instance, containers for foodstuffs can be coated with a non-poisonous metal such as aluminium without the use of a poisonous flux. Metallisation, Ltd., undertakes to advise on coatings for use in any industry and invites those who are interested to see the practical demonstrations of metallisation given daily at the company's stand in the Palace of Engineering in the British Empire Exhibition.

PUBLICATIONS RECEIVED

TEXT-BOOKS OF PHYSICAL CHEMISTRY. Edited by Sir W. Ramsay, K.C.B., D.Sc., F.R.S., and F. G. Donnan, C.B.E., M.A., Ph.D., F.R.S. Vol I. Spectroscopy, by Prof. E. C. C. Baly, C.B.E., F.R.S. Pp. xi+298. London: Longmans, Green and Co., 1924. Price 18s.

MANUFACTURE OF ACIDS AND ALKALIS. By Lunge and Cumming. Vol II. Manufacture of Sulphuric Acid (Chamber Process), by W. Wyld. Pp. xii+424, and Vol. III. The Concentration of Sulphuric Acid, by J. W. Parkes. Pp. xii+394. London: Gurney and Jackson, 1924. Price 31s. 6d. each.

EDITORIAL NOTICES

The Society as a body is not responsible for statements and opinions appearing in the JOURNAL.

Members of the Society, and others, are invited to submit original articles, news, notes and other relevant information to the Editor of *Chemistry & Industry*. Such contributions should be clearly written (preferably typewritten with double spacing), and be accompanied by a stamped and addressed envelope. They will be paid for if inserted. Sources of information should always be given, not necessarily for publication.

Hon. Secretaries of Local Sections and of other Societies are asked to forward notices and reports of meetings as early as possible, and publishers to send books for review, direct to:—THE EDITOR, *Chemistry & Industry*, SOCIETY OF CHEMICAL INDUSTRY, CENTRAL HOUSE, FINSBURY SQUARE, E.C. 2. [Telephone: Clerkenwell No. 2429.]

Hon. Secretaries of Local Sections and of other Societies are asked to note that announcements of forthcoming events cannot be inserted in the next issue of the JOURNAL *unless they are received not later than Tuesday in any week.*

Matters relating to the Transactions and Abstracts, including Papers intended for insertion as Communications, should be addressed to THE EDITOR OF TRANSACTIONS, at the same address.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Vol. 43 NEW SERIES — LONDON, MAY 23, 1924 — No. 21

EDITORIAL

An interesting contribution from Prof. Vegard, of the University of Christiania, appears in *Nature* for the 17th inst. Prof. Vegard has for several years been engaged in the study of the aurora borealis and its spectrum: observations have been made at Tromso, at Bossekop, in Christiania and lately at Leyden. Those who have visited the North of Norway in the autumn know how magnificent a spectacle the aurora may be. Those exhibitions of the phenomenon which we occasionally see in the northern parts of the British Isles, interesting as they are, have not the brilliancy of the sights to be seen north of the Arctic Circle. The auroral spectrum contains lines in the blue and violet identical with prominent lines in the negative band spectrum of nitrogen and a line in the green of wave-length 5577A, which has been a puzzle to chemists and astronomers for a score of years. Vegard concluded several years ago that this line also should be attributed to nitrogen, and he suspected that the nitrogen at the very low temperature of the upper atmosphere was condensed into clusters of small crystals. At Leyden, in the Kamerlingh Onnes laboratory, Vegard investigated the light produced when solid nitrogen is bombarded by cathode rays. He found two green lines, one of them a broad and strong one of wave length about 5577A, and another of wave length 5230A, and other lines proving that the typical auroral spectrum is emitted by solid nitrogen in these circumstances. Liquid nitrogen has been investigated by Dewar, by Baly, Donnan and other chemists. Solid nitrogen melts at $-210°$ C., and the detection of solid nitrogen in the upper reaches of the atmosphere is an interesting contribution to our knowledge of temperatures in regions perhaps a hundred miles above the earth's surface.

The letter from a Californian correspondent on the English language appeals to us in our editorial sanctum. The written language is a tool which may be made remarkably efficient; the use of this tool is an art comparable with that of the engraver or the sculptor. A weekly journal dealing with chemistry is not suited to the practice of this art in its highest form. In too many cases the writing and the proof correcting must be done hurriedly and of our thousands of readers many are content to learn the new facts and value but little the form in which they are presented. Besides, the training of our chemical writers and our chemical editors does not tend to elegance in expression. We wish it were otherwise; to write a simple style, setting down in a suitable manner the story one has to tell, is not a difficult art; it is like skating on the outside edge, perfectly easy to do tolerably with a little practice; it is nothing like so difficult as making losing hazards on a billiard table, which involves great nicety of touch, unusual accuracy and considerable practice. We often wonder that scientific people are not more fastidious in the art of writing: our correspondent gives an instance: he says, the use of etc., although common and accepted as "good English"—common enough it is, but not, we trust, accepted as good English except in very rare instances. Scientific articles and books are not to be taken as standards; every time we read a paper in a chemical or physical journal, we ought so soon as possible to read as an antidote a chapter of the Bible, one of Lamb's essays or a poem by Calverley or Milton. It is now several weeks since we praised the book of an American author, Mr. T. A. Rickard, on "Technical Writing." We offer no excuse for doing this; if an Englishman, a Scotsman, an American or a Welshman, yes, indeed, can show us how to make the tool more efficient or to use it more neatly we are very glad and we are grateful to him. That there is much good sense in Mr. Rickard's book we are satisfied; we have read it through from beginning to end. Whether it is difficult to write well, in a really good style, we do not know; we have never attempted it: we do not write *au grand sérieux*. On the other hand we are satisfied that to write chemical articles, on a variety of topics, in simple language that may be easily understood, is very easy. Many men and women and some children can achieve this. The only trouble is getting the necessary information into one's head; we understand there are some gifted people who can write articles without having their memories charged with the facts. We envy them; for us, learning is,

or rather was, one process, writing another, not to be confused with the first. Mr. Allen's letter, like Mr Rickard's book, comforts us with this reflection great as are the differences between the American and the British journalese, unintelligible as are to us the accounts in the New York papers of baseball matches, there is yet that common language which is used by all those who on either side of the Atlantic make any attempt to write standard English The language of Mr. Abbott, Sir Clifford Allbutt, and Mr. Rickard is the same. If the Americans choose to spell color without the letter "u," they may be forgiven Every English lawyer does the same in his legal documents: we must admit that it is more meritorious to spell it in this way because that is the tradition in your profession, than because you make an innovation of greater simplicity. The one reason is a due regard to precedent, the other a total disregard to the feelings of your fellow creatures It is the difference between orthodoxy and heterodoxy, the one is our doxy, the other is yours

* * *

We see in the columns of the *Manchester Guardian*, which is usually well-informed in such matters, that a decision on the agreement between the British Dyestuffs Corporation and the Interessen Gemeinschaft may be expected within a few days This decision will be eagerly and even anxiously awaited: it is easy to conceive an agreement which would be acceptable to the shareholders of the British company and yet be fatal to the progress of British chemistry and all the industries which depend on it. The views of chemists in this country and of manufacturers here, other than the Dyestuffs Corporation, have been laid before the Government by numerous deputations, of which one from the Federal Council is perhaps both the latest and the last The nature of this particular deputation seems to have been misunderstood by a correspondent who has written to the *Chemical Age*. As the point is of interest, we may remark that the deputation tried to set forth the views of the Federal Council only, not the views of any particular individual, nor those of any society or club in which such individual might be supposed to be specially interested. The Federal Council has no political views and its spokesmen scrupulously and obviously avoided any discussion of the political aspect of the problem It seems to us absurd that anyone should comment on the inclusion in the deputation of someone who has other interests in life besides the Federal Council There is no single member of the Federal Council who has not other important interests, and no just cause of complaint exists that a man, who is able and willing to spare the time, should assist the Federal Council to put forward opinions which represent the collective views of that Council. Suppose the Society of Chemical Industry decided to advocate a particular policy with regard to Chemistry House, has a shareholder in a company any reason to complain that one of the directors who happens to be on the Society's Council has meddled in a controversial and difficult question? In the chemical world an ounce of encouragement is worth a ton of criticism

THE OIL SHALES OF SOMERSET*

By Dr. W. FORBES-LESLIE

The vital need of all industry is cheap fuel. Indeed it is the basic element in human progress and civilisation for upon the form of fuel largely depends the evolution of the human species. Wood was the first fuel used by human beings and has descended to us from primitive man—the splendid civilizations of the ancient world of Persia, Egypt, Greece, Rome and Mediæval Europe belong to this age. Coal followed, bringing into being and subserving the need of the mechanical age. Less splendid and perhaps less durable but more practical and more productive of those essentials for human comfort than the latter. Already the coal age is passing and a new and more potent fuel has seized the imagination of the world and is superseding it in all the realms of industry and commerce. Coal brought the steam engine, the railroad, the steamship. Hitherto the world of the wood age relied for swiftness on the horse, for transport on the wind driven ship. But petroleum, or mineral oil, the new fuel, has increased the utility of the steam engine and the steamship and added speed and ocean range to the latter undreamt of hitherto. Petroleum has also given us the internal combustion engine, the motor car, and, above all, has endowed man with another power over Nature the power of flight, so that he is now bird and man. The characters of fuels vary—wood is solid and flexible, coal is solid and friable, but petroleum is liquid. But petroleum was coal, or in a sense so, and it was wood. Petroleum is only a step further in the complicated process of organic decomposition.

The origin of petroleum oil is to be sought in vegetable and animal remains of past geological periods, which have been entombed in muds and silts with exclusion of oxygen. The same process is seen in action to-day in the deltas of great rivers and in estuaries. These will ultimately become the oil fields of future geological ages. These areas usually occupy subsiding basins and as the load of sediment descends the isotherms, or earth heat units, increase till the organic matter resulting from decomposition is distilled, and escapes as oil, gas and water into adjacent porous rocks, called reservoir rocks, especially if they are flexed or folded, as happens through dynamic action. The oil may remain caught in these tectonic structures for ages and only escape when the drill penetrates them, or through post orogenic changes it may be dissipated in the ensuing convulsions.

Coal also has its origin in vegetable remains of past geological periods, entombed in silts and muds with partial occlusion of oxygen. By artificial means tar oils and benzols can be extracted from it.

But another fuel exists in Nature which is more nearly related to petroleum than coal, both physically and chemically, and that is "oil shale."

Oil shale was known before Colonel Drake discovered the first petroleum well in 1859. Oil shale was known in England in 1694 when a patent was

* Read at a special meeting of the Bristol Section, on May 6

granted for its treatment. It was obtained for medical purposes in 1761 and the first plant was established in England in 1815 at Sunderland. In 1834 oil shales were worked at Autun in France. In 1864 thirty-eight plants were working in Scotland, and as early as 1860 there were fifty to sixty plants working in America. The discovery of well petroleum caused the shutting down of the American plants and ultimately of the French plant at Autun, but Scotland has continued to work throughout the early days of competition and later has been producing about 3,000,000 tons annually with a value of from £750,000 to £2,081,000.

The origin of shale oil is the same as that of petroleum. It arises from vegetable and animal remains entombed in the silts and muds of past geological ages. It may be said that all petroleums were at first in their decompositional evolution oil shale and that dynamical and thermic causes were responsible for their ultimate difference.

Since 1859 petroleum products have gradually usurped the position of coal, and that in a world where industrial development, through increase of population, and more perfect methods of production, has exceeded all previous estimates. Progress in the last 50 years has rushed forward and upward with ever increasing velocity and range of curve till the future appals us by the immensity of its possibilities. How much do we owe this to petroleum and its allied fuels? Much, for the form of fuel underlies the evolution of human progress and creates environment.

The discovery of petroleum in 1859 destroyed the beginning of the oil-shale industry in America and in France, and checked any development of this fuel in other countries, Scotland excepted. To-day the position is reversed. Hear what a leading exponent of the petroleum industry has to say in an article as late as Monday, March 31, 1924, in the *New York Commercial Journal*:—

> "The manufacture of oil and its byproducts from shale rock can now be established profitably in the United States and it is likewise necessary that it be started."

In 1923 the United States of America produced 72·7 per cent. of the total world production of petroleum, or roughly 122,500,000 tons. In 1914 she produced only 44,333,333 tons. In less than ten years the production has increased by nearly 180 per cent. Motor vehicles have increased by nearly 3900 per cent. during the last twelve years and the production of gasoline has only increased by 900 per cent. David White, Geologist of the United States Geological Survey, testified recently before the Senate Public Lands Committee that within five years the United States Navy would have to depend upon foreign oil fields or on oil shale for its supply of oil. Other eminent authorities estimate that the known reserves of petroleum left in the ground in the United States amounts to no more than 9,150,000,000 barrels, approximately 1,525,000,000 tons, and that in ten years or less America will be purchasing oil for her Navy. The United States has 15,000,000 motor cars or 80 per cent. of the world's total, and she uses two-thirds of the world's oil production—a production only kept to its present level by the fortunate discovery of the big Southern Californian Pools in 1921 and 1922. A leading Industrialist of Great Britain reviews the situation as follows:—

> "If their present curve of consumption, especially of high-grade products, is maintained, the Americans, in ten years time, will be importing 500,000,000 barrels of oil a year."

It may also be recalled that while America is consuming two-thirds of the world's oil production she has only 12 per cent. of the known oil reserves remaining in the ground.

The above statements are of serious import and are made by many of the greatest geologists, chemists and statisticians of the United States. The position of the petroleum industry to-day indicates that unless stabilising factors are found demand will exceed supply with the introduction of all the delimiting and degenerating elements which are inherent to such slip backs in industrial progress.

Can these factors be found? The eminent American expert quoted at the beginning of this paper frankly states that the oil shales of America can be profitably worked even on a standard of comparison of prices as finely cut as the oil prices of 1922, which cannot possibly, for lowness of price, ever again recur, the flush production being due to over-drilling and the discovery of the great pools of Southern California. It is stated on good authority that oil shales can be treated in Colorado, Utah and Kentucky for about \$1·50 or about 6s. 6d. per ton, and refined for another \$1·25 or 5s. 3d.—a total of \$2·75 a ton of shale. This will give about a barrel of oil or 42 American gallons, which sells at \$6 per barrel, leaving a profit of \$3·25 net, or about 14s. This is in competition with oil-well production in the same country. Colorado and Utah alone have an estimated oil content in their shales of 12,000,000,000 tons, or 12 times the known oil reserves of the United States.

Here then is the stabilising factor to supplement and to succeed the uncertain oil-well supplies of the present day. If it is possible to work the American shales in competition with idigenous petroleum how much more profitable is it to work oil shales in countries where there is little or no indigenous petroleum like Canada, France, England, Esthonia, Sweden, Germany, Spain, Brazil and Australia.

Although new oil fields have been discovered in other parts of the world, many of those already producing being only in their infancy, still the ratio of demand over supply is such an increasing one that exhaustion even here is foreshadowed.

From these remarks it will be obvious that oil shale and petroleum are not rivals but relatives, seeking to meet conjointly the needs of the industrial world.

This review of petroleum and its position to-day, is also necessary in treating a basic object for any description of the new oil shale discoveries in Somerset. How these appeal to the American mind is best expressed in the words of a well-known oil authority, writing in the American press:—

> "In England, large deposits of oil shale have been known for many years in Norfolk and Dorsetshire, but owing to the large sulphur content about

7 per cent.—they have been unavailable up to this time. A few weeks ago a discovery was reported which undoubtedly will have a most important influence on the industry and commerce of Great Britain."

In such a sense do these Somerset oil-shale discoveries appeal to the American mind.

Now, what are they? They consist of an immense deposit of liassic sediments, concentrated by dynamical causes and chemical interactions into alternate beds of black, blue and brown laminated shales and argillaceous limestones. A great and massive formation. For centuries it has been worked for limestone for making hydraulic limes, but the shales (called locally "scale") were thrown away as waste product.

This massive assemblage of beds extends from Blue Anchor on the West to Combwich on the River Parrett a distance of about 14 miles. It is divided into two dynamical basins by the Devonian ridge of the Quantocks and the Marginal Triassic rocks, viz., the Watchet basin and the Lilstock basin. The latter has a breadth of from 1 to 3 miles, being roughly triangular, and a surface area of about 17 square miles. The former has approximately an area of 3 to 4 square miles, making a total of about 20 square miles. Two main ridges run East and West—one forming the coastal cliffs, the other the inland outcrops. The coastal section dips landwards 25–35 degrees to the south. The inland outcrop dips seawards about 25 30 degrees to the north. The valleys between these being synclinal. The faults are principally in type apical fractures belonging to an anticlinal and synclinal system. Viewed obliquely from N.W and N.E. they appear as a series of step faults with throw downs to the east. The stratigraphy varies in the different series, but a general type is met with throughout. The lithology likewise differs, and these differences are sharply confined to the life zones. The shales are blue, black and brown They have a thickness of from 1 foot to 25 feet and over, are finely laminated or massive, but on weathering even the massive varieties exhibit fine laminations. The fracture is conchoidal, and the note woodeny, the streak brown, the jointing square or triangular A type of flagstones is common in the lower beds. The effect of thermic action is most remarkable Resistance is great and temperatures of even 1000 C., and more, do not flux the rock or cause it to run. It can be burnt under a steam boiler like coal, providing the air currents are kept free Under marine weathering, the oil shales retain their texture, hardness, colour and oil contents for considerable periods. Long atmospheric weathering causes severe oxidation changing the colour to yellow and the rock becomes friable and loses its oil contents.

The formation is divided into seven main series of life zones. This is the most accurate method of division, stratigraphical sequence with lithological equivalents being now relegated to formations where the remains of life are absent. The formation containing the oil shales belongs to the Rhaetic division of the Trias and the Lower Lias division of the Jurassic. An oil shale seam, 10 feet thick, exists in the black shale series of the Rhaetic. It belongs to the life zone of the *Pteria Contorta*, and is the first oil shale discovered in the English Trias.

The basement beds of the lower lias, distinguished by *Ostrea Liassica*, contain several thick oil-shale seams- also called the Contorted beds from the wavy character of its folio planes.

The next is the flagstone oil shales of the *Planorbis* zone. Rich and valuable seams.

The fourth series, called the Lilstock beds, is represented by the *Am. Johnstonii* and consists of black oil shales.

The fifth is formed by thick black and more argillaceous beds of oil shale represented by *Schlotheimia Angulata*, and called the Benholm beds—where best studied.

The sixth, called the Kilve Fill beds, is a thick series containing many seams of rich brown oil-shale, distinguished by the fossil indicator *Am. Arinoceras Walcotti*, and containing at its head a subordinate interlude called Berry's series.

The seventh and superior series is called the Priory beds and consists of about 300 feet of oil shales and limestones representing the zone of *Coroniceras Bucklandi*, and including several subordinate zonal interludes. Superimposed upon this superior oil shale series there are 325 feet of *Gryphaea arcuata* marls with small *Coroniceras Bucklandi* to within 47 feet from the surface, representing the head of the *Bucklandi* zone.

Both the oil shale seams and the divisional planes of the main palaeontological platforms are composed of, and separated by, limestones, the limestones of the divisional planes being constituted of several small paviors with alernating thin mudstones. The whole forming a divisional stage which is usually distinguished by a type of *Am.* resembling *Agoceras megastoma* Wagen whereas the oil-shale seams are separated from each other by thicker beds of pure lias limestones.

The origin of the sedimentation resulting in the deposits above described is now obscure. There is no lithological proof that it was derived from the waste of coal fields occupying the South Wales areas or from the eroded coal measures of Devon. The sediments do not seem to contain mica, fragments of felspars or the partial or unchanged elements of the igneous or plutonic rocks. The texture is so fine that the shales resemble the retrituration of sedimentary rocks They are, moreover, strongly calcareous and weakly argillaceous, whilst their siliceous content is low for this class of rock. There is some difference lithologically between the series The Rhaetic shale is very fine grained, with weaker calcareous content and more argillaceous than the basement lias beds which are weakly argillaceous but strongly calcareous and silicious. The fineness of grain, although great, is not equal to the Rhaetic The *Planorbis* beds are coarser in grain and more strongly calcareous with about equal silicious content The *Johnstonii* beds are of finer grain than the latter and slightly more argillaceous. The *Angulata* beds are of fine grain and are still more argillaceous with considerable calcareous content. The *Arinoceras Walcotti* beds are fine in grain and have about equal

percentages of calcareous and siliceous matter with weak and varying argillaceous content. The Priory beds are less calcareous and more siliceous with stronger argillaceous content.

These differences in lithological texture among the series indicate variation in the quality of the derived sediments and also variation in distance from the source, or changes in the sea floor.

Examination of outcrops West to East give little indication of the derivation of origin. If anything there is growing fineness of grain met with as one goes further East, but so slight that one is led to infer that the outcrops indicate a lateral section of the sedimentation and the cone of it lies either North or South.

The *Ostrea Liassica* beds show some lithological change southwards. Shales thin out and mudstones and thin limestones take their place and fossil indicators and indeed fossil forms of all kinds are rare or absent. Owing to post Liassic or inter Liassic denudation of the southern edges, the upper shale series beyond the Lilstock basin is not available for examination.

Jukes Brown in a redrawing of land and water areas in the Rhaetic and Lower Lias age shows that all Western England was sea and that Cornwall and Dartmoor extended eastwards as a Promontory from an Atlantic or Western Continent. Two wide bays existed extending westwards, one north and one south of the Promontory. These bays are shown to be the debouchment areas of two great rivers draining the border lands of the great Western Liassic Continent. The sedimentation of the Lower Lias was possibly derived from the waste of this continent now lying buried beneath the Atlantic, for the physical character of the deposits and their lithology appear to infer a western system of sedimentation rather than any other.

Chemical Composition of the Somerset Shale

It is, like all oil shales, composed of :— (a) an organic content and (b) an inorganic content.

On treatment by destructive distillation in a retort the shale yields oil, gas and ammonia water and a residue called shale ash. Providing the ultimate temperature is high enough, namely, 800 to 1000° C to volatilise the fixed carbon and drive off the balance of the nitrogen, the ash represents the inorganic content.

The physical characters of the Somerset oil shales *in situ* have already been described. Examination of the shale in the laboratory corroborates these characters and in addition demonstrates that the specific gravity is remarkably high. The ordinary oil shale standard of weight was originally 1·2 from Scotch torbanite and 0·9 to 1·0 from Australian paraffin shales. Owing to poor qualities of shales being now worked in Scotland the sp. gr. has risen above 1·2 to about 1·6 to 1·7. Spanish shales have 1·7 sp. gr. and Kimmeridge shales from 1·2 to 1·7. The Somerset shales have an average sp. gr. of 2·4: the lowest sp. gr. is 1·88, the highest about 3·0. It has been usual to determine the value of an oil shale by percentage of vol.: hydrocarbons to the weight ton. In shales of 1·2 sp. gr. and under, this method is accurate enough, but in higher sp. gr. shales it is obviously misleading. It might be presumed that if the mineral complex was largely composed of lead, the percentage of vol. hydrocarbons would be infinitesimal to the weight ton. It appears that the only accurate standard of percentage ratios is the amount of hydrocarbon in the cube ton. Let the standard be oil shale at 1·0 sp. gr. or the weight of water. A ton of shale of this gravity will weigh 2240 lbs. and measure 1·0 cubic yards. But an oil shale of 2·0 to 2·4 sp. gr. will weigh double, or more than double, of this or 4480 lbs. and still only measure 1·0 cubic yards. Therefore the standard applicable to both is the cubic standard not the weight. Oil is lighter than water and has nothing to do with the atomic weights of the mineral complex. In commercial treatment oil shale is mined or open cast by the cubic yard, retorting is by cubical capacity and Royalties are paid by cubic measurement.

Moisture in oil shales varies. The highest moisture content is met with in the Kimmeridge shales of Norfolk, as high as 25 per cent., also in Esthonian shales and some American shales. Moisture in Scotch shales is low, about 5·7 per cent. and in Somerset shales 4 to 5 per cent.

Unlike most oil shales, Somerset oil shales when freshly broken out give off a strong odour of paraffin. The action of solvents on Somerset oil shales resembles that on American shales, a small percentage of the hydrocarbon being soluble.

The sulphur content of the Somerset oil shales is about the same as that of the Scotch oil shales. Little or no pyrites is met with in the middle series of shales—pyritised fossils being commoner in the Rhaetic beds and in the Upper Liassic or *Coronicras Bucklandi* beds. Retorted oil from the Rhaetic oil shales contains about 2·0 to 3·0 per cent. of sulphur, whilst the Liassic middle shales contain from 0·8 to 2·2 per cent. The sulphur contained in the oil is principally in the form of thiophanes and quite easily washed out, unlike the large percentage of sulphur (7 per cent.) in the Kimmeridge shale oils which is in the form of a thioether, a substance most difficult to eliminate.

The residue, or ash, of the shale after retorting, unless the temperature has been raised sufficiently to volatilise them, contains in the mineral complex 50 per cent. of the nitrogen and all the fixed carbon. The nitrogen content, which has been worked out principally in the middle shale series, is about 0·8 per cent., or a theoretical yield of 80 lb. per weight ton of sulphate of ammonia. On a commercial basis this will give about 50 lb. per ton. On the cube ton a theoretical yield of 160 lb. will be obtained, or a commercial yield of 100 lb. A return of 60 lb. may very well therefore be looked for in commercial production. The amount of fixed carbon in the ash is about 20 to 25 per cent. or equivalent, in a fuel value to one ton of coal in every five tons of oil shale ash. The percentage of fixed carbon depends, up to a point, on the suitability of the retorting apparatus. The more oil obtained the less fixed carbon there will be, the less oil, the more fixed carbon. The object of an operator is to increase the oil yield at the expense of the fixed carbon. Free carbon does, however, exist

in every oil shale in the form of carbonised filaments of plants, algæ, ferns, etc., which have not, and have never been, in combination with hydrogen to form hydrocarbon.

The mineral complex composing the residual ash remains to be examined. Oil shale ash comprehends differing percentages of silica, alumina, iron, lime, magnesia.

The Norfolk Kimmeridge Shale Ash contains :—

	Per cent.	
SiO_2 ..	46·10	
Al_2O_3 ..	19·90	
FeO_2 ..	2·88	8·08%
Fe_2O_3 ..	5·20	
CaO ..	19·60	
MgO ..	1·55	
Sulphuric anhydride ..	3·60	
Alkalis and loss ..	1·17	
	100·00	

Analysis of Scotch Oil Shale Ash yields the following percentages :—

	Per cent
SiO_2 ..	49·70
Fe_2O_3 ..	16·80
Al_2O_3 ..	18·80
CaO ..	2·40
MgO ..	2·20
Alkalis, sulphur and loss ..	10·10
	100·00

Analysis of American Shale (Indiana), including carbon :—

	Per cent
Carbon ..	11·00
SiO_2 ..	59·20
FeS ..	12·20
Al_2O_3 ..	17·50
CaO ..	0·10
MgO ..	0·14
	100·14

Analysis of Somerset Oil Shale exhibits the following compositions :—

	Per cent
SiO_2 ..	26·56
Al_2O_3 ..	13·22
Fe_2O_3 ..	10·26
CaO ..	36·83
MgO ..	1·10
SO_3 ..	10·52
Alkalis CO_2 and Loss ..	1·51
	100·00

Total organic volatile matter averages 33%.

A study of these ultimate analyses of various shale ashes show that the Somerset oil shales differ from Scotch, American and Norfolk Kimmeridge in the silico-calcareous ratio, whilst closely approximating to Scotch, American and Norfolk Kimmeridge ash in the Al_2O_3, Fe_2O_3, and MgO contents; the difference in SiO_2 and CaO is most marked. SiO_2 forms invariably the highest percentage in oil shale ash residue and Al_2O_3 is generally the next highest—CaO commonly forms one of the subordinate percentages. But in the Somerset oil shale CaO is the major percentage, SiO_2 being subordinate by one-third. Only one oil shale of the Green River Formation, Wyoming, approaches the Somerset in the silico-calcareous ratio, viz., as follows :—

	Per cent
SiO_2 ..	38·9
Al_2O_3 and Fe_2O_3 ..	12·4
CaO ..	38·3
MgO ..	4·9
	94·5

But even here the silico-calcareous ratio is reversed, SiO_2 being still a plus quantity. This silico-calcareous ratio therefore is remarkable, and marks Somerset shale as an uncommon oil rock. The peculiar character of the mineral complex may have an influence in determining the high quality of the Somerset oil. The best petroleum oils are usually found in calcareous rocks, as in the Pennsylvanian and Persian fields.

When an oil shale is destructively distilled oil, gas and ammonia water are obtained. The water is largely the result of steam used in the distillation. But water of combination is also a product. The ammonia is a product of the decomposition of nitrogen, and about 50 per cent. of the nitrogen content of an oil shale is recovered from the ammonia water—the other 50 per cent. being recovered from the residue.

The gas is composed of permanent gases such as CO and CO_2, but also contains a percentage of the more volatile hydrocarbons of the methane series with hydrogen and nitrogen. The gas is scrubbed being driven through scrubbing towers, and the light hydrocarbons or scrubber spirit is absorbed by heavier oils, which, on being distilled, yield up the spirit—about 2 gallons of scrubber spirit may thus be recovered to the ton of oil shale.

The amount of permanent gas does not vary much in oil shales of equal or comparative richness in oil content—being about 2500 to 3500 cb. ft per weight ton of shale.

Origin, Composition and Properties of the Oil

Oil shales, with the known exception of the Montery shales of California, do not contain oil as such. Oil is obtained as a product of pyrolysis in the destructive distillation of the shale. The mother substance of oil in shale has been described by Prof. Crum Brown, who called it "Kerogen." Little information is available on the chemical composition of kerogen, but in Scotch shales it has been found to consist of 73·05 per cent. carbon, 10·62 per cent. hydrogen, and 16·33 per cent. oxygen. This composition corresponds to the formula $C_6H_{10}O$, which is believed to be the empirical formula of kerogen. Although the empirical formula of kerogen has been determined as $C_6H_{10}O$, it is nevertheless probable that kerogen is composed of different types and sizes of molecules, and this may serve to explain the difference in the shale oils. Besides oxygen, hydrogen and carbon, kerogen contains small percentages of nitrogen and sulphur. Kerogen is only slightly soluble in carbon disulphide, and for this reason is classed as a pyrobitumen. Certain of the pyrobitumens, on being treated, change into bitumen, becoming soluble in organic solvents.

The oil-producing substances of shale are therefore considered to be asphaltic pyrobitumens, and on

being treated they change into a bitumen which is largely soluble in organic solvents and after extraction from the shale becomes a semi-fluid or asphalt-like substance. The decomposition or conversion of the pyrobitumen into a bitumen is not clearly understood. Perhaps it may be due to complete or partial polymerisation. It proceeds at a temperature of 400° C. and over, and produces gas, oil, vapour and fixed carbon, but the change of kerogen into bitumen will take place at much lower temperatures if sufficient time be allowed. There are therefore two stages in the distillation of oil shales :—

(*a*) The conversion of kerogen into bitumen.
(*b*) The decomposition of bitumen into gas, oil, vapour and fixed carbon.

Both of these stages probably occur at the same time or relatively so.

Destructive distillation of oil shale is effected in closed chambers called retorts. There are two types of these—vertical, of which the Scotch retorts are an example, and horizontal, of which the Neilson and Fusion are present examples. The vertical are oval-shaped iron and fire-brick lined towers about 65 feet high. The Neilson is a revolving horizontal fire brick lined tube about 100 feet long. The Kimmeridge shales, and most of the American and Australian, are unsuited to present types of vertical retorts owing to their sensitiveness to thermic changes, but a lead jacketed retort, the New York retort, that was invented in America is claimed to preserve a regular retorting temperature. If so, it will revolutionise American oil-shale practice. Those classes of oil shales which are resistent to irregular and high temperatures are eminently suited for treatment by the Scotch vertical type of retort. Among such the Somerset oil shales are prominent, an oil being obtained 80 per cent. saturated by vertical retorts. On refining, such oil resists cracking even at temperatures of 410° to 450° C. This quality confers an enhanced value on an oil because this quality is passed on to the various fractions into which a crude oil is split and increases their market value and range of utility correspondingly.

Properties of Crude Shale Oil.

A shale oil should be fluid or semi-fluid at ordinary temperatures. Scotch crude is semi-solid at ordinary temperatures, and so are most American shale oils. Crude shale oil is usually of a dark rich brown or greenish brown colour. It rotates the pole of reflected light to the right. The index of refraction is increased in shale oils of large unsaturated percentage, it is also increased by an increase in viscosity, whilst the presence of wax in lubricating oil lowers it. Somerset oil is fluid at ordinary temperatures, but its viscosity quickly increases in winter temperatures. The sp. gr. of Canadian shale oil varies from 0·891 to 0·977, on an average about 0·900. American shale oils vary from 0·877 to 0·975 and the average about 0·898. French crude oil has a sp. gr. of 0·912. Kimmeridge Norfolk 0·990. Scotch crude shale oil varies from 0·8750 to 0·9032, average about 0·8917. The sp. gr. of Somerset shale oil varies from 0·933 to 0·940.

The chemical composition of a crude shale oil varies in different fields. The variation largely depends on the relative percentages of saturated and unsaturated hydrocarbons. The saturated series are the paraffin (C_nH_{2n+2}) and naphthenes (C_nH_{2n}): the unsaturated are the olefines (C_nH_{2n}), diolefines (C_nH_{2n-2}), acetylenes (C_nH_{2n-2}) and aromatic benzenes (C_nH_{2n-6}). Crude shale oils usually contain fairly large amounts of pyrrol (C_4H_5N), pyridine (C_5H_5N) and quinoline (C_9H_7N). Sulphur compounds are also present such as hydrogen sulphide, carbon disulphide, alkyl sulphide or thioethers such as $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!S$, thiophenes, thiophanes ($C_nH_{2n}S$) and mercaptans.

American shale oils are from 41 to 65 per cent. unsaturated; Kimmeridge (Norfolk) from 85 to 90 per cent. unsaturated; Esthonian shale oils from 90 to 95 per cent. unsaturated. Scotch shale oils contain from 30 to 40 per cent. unsaturated hydrocarbons. Somerset shale oil, on the contrary, is only 20 per cent. unsaturated. The unsaturated hydrocarbons in the Kimmeridge shales belong largely to the olefine and acetylene series; Somerset largely to the olefine series; American to the olefine, diolefine and acetylene series. Among these percentages of saturated and unsaturated hydrocarbons are contained the organic sulphur compounds. Thiophanes occur as the sulphur compound in Somerset shale oil and thioethers in the Kimmeridge shale oils. The thiophanes are easily washed out; the thioethers are obstinate to eliminate. Nitrogen occurs as pyridine in the American shale oils, as pyridine and quinoline in the Kimmeridge (Norfolk) shale oil, and probably as pyridine in the Somerset.

On refining, a crude oil, whether petroleum or shale oil, is broken up into fractions by a series of thermic cuts. The lighter gaseous hydrocarbons are driven off first and condense as a spirit, followed in series by the liquid and solid hydrocarbons.

Description of the Fractions

The petrol in American shale oil is usually in large quantity, up to and over 35 per cent. This is very high, even for the best Californian or Pennsylvanian petroleums, but it is "cracked": that is, it contains large percentages of unsaturates, and in the refining treatment which requires desulphurisation and subsequent washing in caustic soda a large part of the unsaturates are lost. The same applies to Esthonian shale oils and Kimmeridge: as much as 70 to 75 per cent. may be lost in a shale oil of high unsaturation. A shale spirit will change in sunlight to a straw-coloured liquid, and even to a red ruby liquid, due to decomposition of unsaturated hydrocarbons. Gums and resins may be thus precipitated, and will cause mechanical trouble in the motor car. Consequently it is necessary to free the spirit from all decomposible unsaturates. Sulphur also is always present, and in its most objectionable form, in cracked oils. Scotch oils contain smaller percentages of petrol than either American, Esthonian or Kimmeridge oils, but the Scotch oil is more largely saturated than most of the American and than the Kimmeridge and Esthonian. The Somerset shale oil contains

9·9 per cent., and with the scrubber spirit the percentage is increased to about 13·9 per cent. This spirit contains no unsaturates, or only a small amount and is "water white" on being refined, keeping its colour equal to the best petroleum petrols.

The kerosene fraction from 180 degrees C. to 240 degrees C., is equally high in crude American petroleums or shale oils, as much as 27 per cent. in Utah shale oil; in Scotch, about 14 to 23 per cent.; in Kimmeridge (Norfolk) it reaches a point even higher than American shale oil, viz., 33 per cent. In Esthonia it is higher still, about 44 per cent. Somerset shale oil contains only 11·9 per cent. of

Fractionation of an American Shale Oil from Utah in this country gave the following:—

		Per cent.
50° C.–180° C.	Petrol	35
180° C.–240° C.	Kerosene	27
240° C.–280° C.	Gas oil	15

kerosene being the smallest percentage of the above quoted examples.

The gas oil fraction is 15 per cent. in Colorado shale oils, 30 per cent. in Scotch, and only 3·5 per cent. in Kimmeridge (Norfolk). In Esthonia 5·7 per cent., and in Somerset, 28·2 per cent. High percentages of gas oil are not considered an advantage in a shale oil or petroleum, owing to the prices being so much less than for petrol, kerosene, or light lubricating oil. The 28·2 per cent. is too high in Somerset shale oil, and by careful refining it has been found possible to reduce this percentage to about 5·7 per cent.—increasing the kerosene and light lubricating fractions correspondingly. Most gas oils are solid at ordinary temperatures, but Somerset gas oil is fluid, and forms a high-grade Diesel oil for naval use.

Of all fractions, however, in ... shale oil the most valuable are the light and heavy lubricating oils. The Scotch shale oil usually contains 14 ... per cent. of light, and 15 per cent. of heavy lubricating oil, but since 1922 it produces only 8 per cent. of light and heavy lubricating oils. Kimmeridge shale oil, 31 per cent. light and heavy, and Esthonia 25 to 27 per cent. but these latter are of poor grades, due probably to the high percentage of unsaturates. A ... (Colorado) shale oil has about 10 per cent. lig... 5 per cent. heavy lubricating oil of sp. gr. ... 0·959, but these likewise appear to be of poor ... The principal value in the Somerset shale o... oil.

... and the large percentage of its lubricating fractions, a... first-grade quality possessed by them. It has 2... 27·5 per cent. light lubricating oil, and 18·7 per cent. heavy lubricating oil. The resistance of the shale to heat has been transmitted to its lubricating oils, so that no cracking of the heavy lubricating oil takes place up to 410 to 450 degrees C. A remarkable and most valuable quality, especially when, in addition, it has the quality of "oiliness" and semi-fluidity at ordinary temperatures. It is certainly one of the purest, if not the purest, high-speed lubricant found in shale oils. In commercial practice it has been applied to "seized" red hot bearings; it has cooled them off, and when collected has been found, and unchanged. It compares favourably with the best Russian lubricating oils, and its discovery in this country may be regarded, in the words of a naval

authority, "as a miracle." The sp. gr. of lubricating oil is 0·960–0·990.

Paraffin wax is found in most of the American shale oils, and in such percentages in some as to make the oil solid at ordinary temperatures. Scotch oils are somewhat similar, but Kimmeridge oils (Norfolk) have low percentages. Utah (American) shale oil contains about 5 per cent. paraffin wax: Scotch shale oil contains about 12 per cent. paraffin wax; Somerset shale oil contains about 3 per cent. paraffin wax.

The "still coke" obtained from the ultimate distillation of the Kimmeridge (Norfolk) and Somerset shale oils is of fine quality, suitable for varnishes. Norfolk shale oil possesses another by-product of great value in its large ichthyol fraction, which is closely connected with its high sulphur content.

A combination of the residual shale ash with the Lias limestone, and subjected to a special process, gives a high quality Portland cement. It sets within seven hours, and it seems as if the age of cheap high-grade cements were at hand. The shales can be used for the manufacture of high-class bricks and tiles, and for, it is believed, the manufacture of excellent fire bricks.

But what we would impress upon our hearers most of all is that there is between Watchet and the Parrett one of the most stupendous sources of cheap fuel, heat and power in Europe. You may forget the oil, the cement, the nitrogen, the by-products, but you cannot forget that there are thousands of millions of tons of high-grade fuel open for blasting down, each ton or every two tons of which is equal in evaporating value to a ton of the best coal.

What a national asset.

What industrial expansion does this discovery indicate?

MINERALS OF THE EMPIRE

The Imperial Mineral Resources Bureau has an inquiry office at the British Empire Exhibition for the purpose of answering queries and of directing inquirers to various Empire exhibits. To assist in this useful work, the Bureau has compiled a special descriptive and statistical account of *The Minerals of the Empire*, a well-printed volume of 314 pages, which is on sale, price 5s., at the Exhibition. The volume is provided with a frontispiece showing the proportion of the world's output of the more important minerals that were produced in the British Empire in 1922, and there are chapters devoted to the various minerals. Each chapter contains a succinct account of the principal occurrences of each mineral within the Empire, information enabling the visitor to locate the exhibitors of the mineral and its chief products, notes on commercial grades and uses, and statistics of production and trade. The volume will be indispensable to all visitors wishing to study the exhibits of minerals and their products at the Exhibition.

THE PHENOMENA OF ROTATION DISPERSION—A REPLY TO PROF. PATTERSON

By HAROLD HUNTER

In an article published in *Chemistry and Industry* of May 2 (p. 454), Prof. Patterson subjects the views of those who regard dynamic isomerism as the cause of anomalous rotatory disperson to somewhat trenchant criticism. It is far from being the writer's object to reply to these criticisms—in fact, in the main he agrees with them—but the views put forward by Prof. Patterson appear to call for comment.

In the first place, it can hardly be said that the empirical period in the development of our knowledge of optical activity has come to an end. There is no theory extant which will explain any of the facts of optical activity, still less is there one to account for rotatory dispersion in anything but a very incomplete manner. Both Prof. Patterson (*loc. cit.*) and Prof. Baly (*ibid.*, 331) appear to regard the Drude dispersion theory with a certain amount of suspicion and distrust. In the writer's opinion, however, no progress whatsoever can be made by chemists in the field of optical activity until a physicist of Drude's genius shall arise and give the matter his attention. It is significant of the difficulty of the subject that since the deaths of Drude and Voigt, no scientist has proved capable of approaching the subject from the theoretical side.

The attitude of the writer and his colleagues of the Battersea Polytechnic towards this problem is mainly experimental. The views of both Professors Lowry and Patterson have been subjected to the acid test of experiment, and have been found wanting. It is not correct, therefore, for Prof. Patterson to say "that Dr. Pickard now also supports the views which were put forward by me in 1916."

The first suggestion put forward by Prof. Patterson, with the object of generalising the subject of optical activity was published in 1913, and may be termed the "sine curve" theory. The suggestion was made that the temperature-rotation curve for any active body is periodic in character, but variable in period, amplitude, and phase. As a first approximation, "mainly as a concrete example and for purposes of illustration," he proposes an equation of the form $a = e^{at} \sin (bt + c)$, where a, b and c are the parameters of amplitude, period and phase, respectively (*J.C.S.*, 1913, **103**, 156). There are three obvious objections to this expression. First, no physical significance can be assigned to the sine of a temperature. Second, the exponential term e^{-at} is, in itself, suspicious. The exponential equation is beloved of the empiricist because it may be made to fit so many experimental results. But the fact that it can be made to fit a given set of figures is no guarantee that it is the correct equation to apply—no theoretical deductions whatever can be drawn from its use. It is a tower of strength to the engineer who frankly admits his ignorance of the function with which he is dealing, and who uses the equation only as a means of interpolation between his experimental results. This is its legitimate sphere (unless, of

course, there is other evidence that the function really is an exponential one), and it is utterly useless as a method of extrapolation. Indeed, unless it is very guardedly employed, it may become a source of positive danger because it tends to assume a spurious appearance of accuracy, and may therefore be accepted as a natural "law" by the unwary. The third objection is more of a practical nature. The temperature-rotation curves of many substances are very nearly linear over a temperature range of nearly 200° C. The period of a sine curve of the above type must be very large in order to accommodate a linear curve for this great temperature range. This objection alone robs Prof. Patterson's suggestion of most of its claim to be regarded as a valuable contribution to our knowledge of the subject.

But he proceeds to develop his hypothesis still further. Having decided on his fundamental temperature-rotation curve, he assumes that the effect of some solvents is to bring hitherto inaccessible portions of the curve into the region of experimental observation. Still bolder, he imagines that a family of chemical compounds has one fundamental temperature-rotation curve—the curve, so to speak, of the parent substance—and that the derivatives of this parent compound have temperature-rotation curves which form part of the fundamental. Further, the greater the difference between the chemical constitutions of the parent compound and the derivative, the farther apart will be their observed temperature-rotation curves on the fundamental one.

So far, light of one wave length only has been considered. Prof. Patterson considers that the temperature-rotation curves for light of other wave lengths are similar ones which, however, differ considerably in amplitude, and sometimes also slightly in period and in phase. He then points out that anomalous rotatory dispersion occurs when the temperature-rotation curves for light of different refrangibilities are displaced slightly in phase, so that they do not intersect at one point.

It must be confessed, however, that this "sine curve" theory has very little to recommend it. Not only does it fail to co-ordinate the observed experimental facts, but it also requires a good deal of faith for its acceptance even when limited in its application to very few compounds. The periodicity pointed out by Prof. Patterson is very difficult to observe, even in his own results; no trace of it is to be found in the results obtained by other investigators. The practice of extending, for example, the temperature-rotation curve for a substance in the homogeneous condition by grafting on to it the temperature-rotation curve for the same substance in some solvent is entirely indefensible, more, it is impracticable. There is no guarantee that the scales of temperature and rotation respectively are the same in each case. Furthermore, it can be shown that closely related compounds do not always have similar temperature-rotation curves; *d-sec.* octyl formate (*J.C.S.*, 1923, **123**, 1) and acetate (*J.C.S.*, 1914, **105**, 861) form a case in point. The former compound has not been observed to exhibit anomalous rotatory dispersion in the visible region of the spectrum, but consideration of its temperature-rotation curves for light of different wave lengths shows that it may do so at a temperature in the neighbourhood of -50° C.; *d-sec.* octyl acetate, on the other hand, has been observed to show anomalous rotatory dispersion in the visible spectrum in the homogeneous state at a temperature of about 160° C. That is to say, the change in constitution produced by proceeding from the formate to its next higher homologue has caused the point of intersection of the temperature-rotation curves for light in the visible region of the spectrum to move over a temperature range of about 200° C.

For the purpose of this discussion, however, the chief interest of Prof. Patterson's work lies in two papers published in 1916, which he quotes in his article. In these papers he puts forward some views on the subject of rotatory dispersion, and criticises those supported by other workers. His remarks on the rational zero are interesting.

The Rational Zero

"In the early days of optical activity it was supposed that the specific rotation of a compound would be a genuine constant independent of external conditions, and although this expectation was grievously disappointed, there still exists a hope that dispersive power may prove to be sufficiently independent of external conditions to serve for the definite characterisation of the substance to which it pertains" (*J.C.S.*, 1916, **109**, 1176).

This idea underlies the first of these papers. Prof. Patterson, of course, uses a dispersion ratio as a measure of dispersive power. But he finds, as indeed every worker in this field has found, that dispersion ratios are by no means independent of external conditions in every case. Instead of accepting this fact, however, and endeavouring to determine the conditions under which dispersion ratios *are* constant, he sets out to find a way of calculating dispersion ratios in order to *make* them constant. He says that "the dispersive power, in order really to be useful, must remain constant, or at least approximately so, with varying circumstances, and not have arbitrary normality or anomalousness (*sic*) in accordance with purely accidental circumstances, such as a very slight change of temperature, or solvent, or concentration" (*Ibid.*, 1177). The wisdom of this statement is very much open to question. There is very little merit or use in constancy *qua* constancy; that is, a constant is useful only when we know what it means, for only then can a meaning be assigned to any particular deviation. Now, no meaning can be assigned to a dispersion ratio—it is entirely arbitrary. It is true, of course, that the ratio is constant for substances exhibiting simple rotatory dispersion, but for those with complex, and especially for those with anomalous rotatory dispersion, it can, and does assume many values. However, Prof. Patterson, having decided that dispersion ratios are not sufficiently constant for his purpose, proceeds to calculate them anew with a view to the introduction of the necessary constancy. To do this he introduces the new conception of the "rational zero." From a consideration of various temperature-rotation curves and characteristic diagrams, he comes to the conclusion that the zero of the polarimeter has little or no

physical significance, and proposes to substitute for it the rational zero, which is the rotatory power of the particular substance under consideration at which the lines on the characteristic diagram for these two wave lengths intersect. Then, as Prof. Patterson points out, if this point be regarded as the zero of rotation, dispersion ratios calculated from it are found to be much more constant than if calculated in the usual way from the physical zero of the polarimeter. Of course, they are: provided that the lines on the characteristic diagram are straight, which is very often found to be the case, it follows that this suggestion is merely a piece of geometrical legerdemain, in which the properties of similar triangles are employed to obscure the real scientific issue.

The announcement of the fact that the use of the rational zero imparts constancy to the dispersion ratio is thus the rediscovery in a particular form of facts which have been known to science for at least two thousand years. But the main objection to the proposal is far more serious. Prof. Patterson cannot be unaware of the fact that there are two kinds of characteristic diagram; those in which all the lines intersect at one point, the zero of rotation: and those in which the lines do not intersect in one point. These two types correspond to substances with simple and complex rotatory dispersion respectively. Furthermore, it follows from the Drude equation with two terms that in characteristic diagrams of the second type, no more than two lines can intersect at one point, and no two lines can intersect on the axis of zero rotation. Therefore, for substances of the second class, Prof. Patterson's suggestion leads logically to the postulation of an infinite number of rational zeros, depending on which particular two of the infinite number of wave lengths at his disposal he chooses for the calculation of the dispersion ratio. And all this for one substance only; for any other, the rational zeros will be different. Even if the validity of the Drude equation be not admitted, we cannot get away from the undoubted experimental fact that substances *do* exist, for which the lines on the characteristic diagram do not all intersect at one point, and for which, therefore, a large number of rational zeros would be required. The conception of the rational zero, then, must be dismissed as unworthy of further consideration; it was designed for a purpose which has been shown to be unscientific, and its adoption leads to a labyrinth of arithmetical computation from which there is no escape.

In the second of these papers, Prof. Patterson criticises the Drude equation and the conception of dynamic isomerism as an explanation of the phenomenon of anomalous rotatory dispersion. His objections to the Drude equation are twofold. He says that it "is based on very hypothetical grounds, and is already gravely suspect by reason of the fact that it ignores the influence of temperature on rotation." (*Ibid.*, 1193.)

The first objection is very easily met. The electronic theory of light, like many other theories, is certainly hypothetical, but its success in correlating the very varied phenomena of optics is such that it will require more than mere assertion to shake it. The second objection is ingenuous in the extreme. The Drude equation certainly ignores the effect of temperature on rotation. It is a dispersion equation, pure and simple, and does not pretend to deal with temperature effects. It is tacitly assumed, naturally, that rotations for different wave-lengths are to be compared at one and the same temperature. Would Prof. Patterson seriously assert, for instance, that Boyle's law "is already gravely suspect," because "it ignores the influence of temperature" on pressure or volume? Yet the two cases are exactly similar. Just as Boyle's law was extended to include the influence of temperature by the discovery of the law of Charles, and the combined equation was modified subsequently by Van der Waals to introduce the effects of mutual attractions and the volumes of molecules, so, it is hoped, will the rotation constants and dispersion constants of the Drude equation be modified to express the change of temperature and of solvent. For the present, however, this is merely an aspiration; much work must be done before the effect of experimental conditions on the constants of the Drude equation is even dimly understood; for the time being we must be content with the knowledge that the modifications we seek must surely be found because the search is being conducted in a logical manner.

Prof. Patterson does not approve of the postulation of dynamic isomerism in order to explain anomalous dispersion, and here, perhaps, his attitude is understandable. A dynamic isomeride of a compound is essentially one which cannot be isolated and put into a bottle. Postulation of the existence of such isomerides immediately denies an opponent the right of challenging one to produce the compounds duly labelled and analysed. But to ignore the fact that dynamic isomerism does occur in many cases known to chemists is hardly scientific. It is known, too, that labile isomerism is sometimes accompanied by complex rotatory dispersion, and further, in some cases where complex rotatory dispersion has been observed, the occurrence of dynamic isomerism is certainly not improbable, and in many of the cases it has been shown purely on chemical grounds to be highly probable. The following, which seems to the writer, to be the really important objection to this hypothesis is not, however, mentioned by Prof. Patterson. It is difficult to understand why a very slight change in constitution—often merely the redistribution of the valency forces amongst three or four of the atoms in the molecule—should have in some cases such an enormous effect on the optical properties of the molecule as not only to cause its rotatory power to change sign, but also to alter the value of its rotatory dispersive power.

But the fact remains that the Drude equation forms what is at present the only means of explaining anomalous rotatory dispersion—its nature, and under what conditions it may occur. It is not merely the most accurate formula extant—it is the only one. Its opponents have not yet proposed a substitute. They are at present in the vague stage, and are content with statements such as "the potentialities of the asymmetric carbon atom and of the most simple physical conception of those intermolecular forces to which liquefaction is due are ample to

account for all the observed behaviour" (*J.C.S.*, 1913, **103**, 173), and the like.

It is certainly unfortunate that of all the causes which may give rise to a multi-term Drude equation, and hence to complex and possibly anomalous rotatory dispersion, dynamic isomerism has been singled out almost to the exclusion of the others. It must not be forgotten that for complex rotatory dispersion to occur, all that is necessary in the medium is the presence of two rotatory electrons of different period. We are not compelled even to assume that these electrons exist in different molecules, much less that the different molecules are dynamic isomerides. Association, dissociation, solvate formation, ionisation, and the superposition of the partial rotations produced by different asymmetric complexes within the same molecule may also be causes giving rise to optical heterogeneity, such as determines complexity of rotatory dispersion. The fact remains, too, that by means of these phenomena we are able to explain with remarkable success the varied aspects of rotatory dispersion. It is true, of course, that the hypotheses are incapable of direct proof, or even, at present, of direct experimental test, but it is maintained that they are not inconsistent with facts observed in other branches of chemical science, and that they provide what is at present the only satisfactory explanation of the facts of rotatory dispersion.

London, S.W. 11

MEETING OF THE INTERNATIONAL UNION IN COPENHAGEN

As we have already announced, the meeting of the International Union of Pure and Applied Chemistry will be held this year in Copenhagen from June 26 to July 1. The following is the provisional programme:—

On Thursday, June 26, there will be a reception of the delegates at the Raadhus (Town Hall) by the Municipality of Copenhagen. The Council meeting will be held at 9 a.m. on June 27, followed by the general meeting at 11 a.m., meetings of the various committees at 2 p.m., and a reception at 8.30. On Saturday, June 28, there will be meetings of the committees and addresses will be read at 4 p.m. On Sunday there will be an excursion, followed by a lunch given by the organising committee. The committees will meet again on Monday morning, June 30, and in the afternoon there will be addresses and a visit to the Carlsberg brewery. More meetings follow on July 1, and the final general meeting will be followed by a banquet given by the organising committee. British chemists who wish to attend this meeting should communicate at once with the Hon. Secretary of the Federal Council, at Central House, Finsbury Square, London, E.C. 2.

NOTES FROM HEATHFIELD V.

By the Rector, Rev. B. V. WHITE

Dear Mr. Editor,—A few days ago I was walking to Middlesmoor in pursuit of natural knowledge, when I fell in with a young man who was recently a sergeant in the British Army in the north of France. He was, for a period, under the command of a Captain Wimperis or some such name, in a baking establishment near Boulogne, and when discharged from the army he returned to his native village, Ramsgill, in this dale. I have had more than one talk with him about the scientific methods of baking and have also learned additional facts from an acquaintance of mine at Arncliffe in Litton dale, and think you may be interested in the observations I have been able to collect. In this part of England everyone bakes at home, and though I have been a considerable traveller and have visited nearly every village in the dales, and, in addition, Cambridge, London, Carlisle and Durham, I can truthfully say that no one bakes better bread than we do in Nidderdale, and very few do it as well.

The chemistry of bread-making is not remarkably simple. It is well known that flour is mixed with nearly half its weight of water and a little salt. To this is added some milk and water mixed with yeast and the whole thoroughly kneaded; there is no magic in the kneading—this is merely thorough mixing. After kneading, the bowl of dough is placed in front of the fire and the dough gets gradually warm and rises. Here the chemical actions begin; the flour generally contains some 2 or 3 per cent. of sugar, the milk also contains a small percentage of sugar, and the enzymes present in the flour convert a portion of the starch in the flour into sugar. The yeast ferments the sugar, forming carbon dioxide and alcohol; while the dough is rising the carbon dioxide forms bubbles of gas, separated from each other by thin walls of gluten and more or less gelatinised starch. When the due time has elapsed the bread is put into the oven; this should have a temperature of 450° or 500° F., which ensures that the outer layer of the loaf is made into a dry and nearly impervious crust of a brown colour due to the heating of the sugar in the dough. The inside of the loaf, when properly baked, seems never to have attained quite the temperature of boiling water, which has always seemed strange to me. The baking dries off water from the outside of the loaf but not the inside; it causes the carbon dioxide to expand and make larger bubbles, it drives off the alcohol caused by the fermentation and some of the carbon dioxide and it assists the water to gelatinise some but not all of the starch in the flour, making an elastic colloidal substance—using the word colloid to mean glue-like, as it did when I was a boy. The effect of the salt is to increase the elasticity of the gluten and the gelatinised starch; no doubt soda or alum or green vitriol would have a similar effect, though bread made by such means would not be very palatable. The loaf when it comes out of the oven contains very nearly as much water as when it was put in, that is, about 40 per cent.; the les

of weight in baking is about 10 per cent., and this is almost entirely due to the conversion of starch and sugar into carbon dioxide and alcohol.

The loaves are now allowed to cool slowly in front of the kitchen fire. Sudden cooling weakens the partitions between the bubbles of gas and so spoils the loaf. I am not aware that any chemical change of importance goes on during the cooling, but if the cooling is too quick some of the water vapour which should disappear into the air is apt to condense on the loaf as a sort of dew and the bread may turn mouldy.

If the bread is kept too long before it is eaten, it goes stale; the bread tastes dry in the mouth and is not so pleasant to the taste. Now stale bread is not really drier than fresh bread; it only seems so. Analysis shows that it still contains about 40 per cent. of moisture, just about the same as when first drawn from the oven. The change which occurs when bread goes stale is not loss of moisture but rather some kind of redistribution of moisture within the loaf. Flour is mainly composed of starch, a carbohydrate of the type $(C_6H_{10}O_5)_n$ where n is a large number, perhaps 200 in the case of ordinary starch. Starch may, by suitable means, be converted into a soluble variety less complex than the ordinary variety. Starch, as found in flour, seems to contain two substances, one of which is probably a polymer of the other; these are known as amylopectin and amylocellulose. It is the more complex amylopectin which assists the elasticity of the dough; it is the amylocellulose which forms soluble and semi-soluble starches of comparatively simpler constitutions. These, in fresh bread, remain in a gelatinous state and contain a notable proportion of soluble starch. When the bread becomes stale the proportion of soluble starch in it becomes much less, the solid part of the loaf becomes dry and insoluble instead of an easily swallowed jelly. I have sometimes observed in a paste-pot which I keep on my writing table a change in the appearance of the paste which I take to mean the conversion of a soluble into an insoluble variety.

I take it that starch and inulin and similar substances, perhaps even sugars, in plants are stores of foodstuffs and raw materials which the plants can make use of in times of need, as animals are said to be able for a short time to live partly by absorbing their own fat. As to the nature of enzymes, I remember, as Shakespeare says in *Othello*, a mass of things but nothing distinctly. I regret that I do not even really know whether enzymes are substances or merely complex phases of a substance. If we could isolate an enzyme, would it have a definite molecular constitution or is it merely a singular complexity which may arise in a variety of large molecules? I feel sure that many of your readers can answer this question. My friend the sergeant was, I gather, too busy with the supply of loaves to the troops to devote his spare time to enzymic niceties. I fear that I draw out the thread of my verbosity finer than the staple of my argument, and remain, with all due deference and regard, etc., etc.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

A preliminary programme appears on this page.

In accordance with the provisions of by-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting: Dr. E. F. Armstrong, F.R.S., *President*; Mr. Julian L. Baker, Mr. C. S. Garland, Sir Max Muspratt, Bart., and Sir Wm. J. Pope, K.B.E., *Vice-Presidents*; Mr. John Allan, Prof. J. W. Hinchley, Dr. J. H. Paterson, and Mr. W. J. U. Woolcock, C.B.E., *Ordinary Members.*

Mr. W. J. U. Woolcock, C.B.E., has been nominated for election to the office of President under by-law 19; Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., have been nominated Vice-Presidents under by-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been re-elected Hon. Foreign Secretary.

Mr. W. A. S. Calder, Mr. W. H. Coleman, Mr. Wm. Cullen, LL.D., Mr. F. W. Gamble, Mr. James MacGregor and Mr. J. Arthur Reavell, have been nominated under By-law 24 to fill four vacancies among the Ordinary Members of Council.

A Ballot List is being posted to every member entitled to vote.

J. P. Longstaff,
General Secretary

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

Wednesday, July 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. The President, E. Frankland Armstrong, Esq., D.Sc., F.R.S., will give a technical address entitled:—"A Neglected Chapter in Organic Chemistry: The Fats." *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

Thursday, July 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*: Annual Dinner of the Society at the Midland Adelphi Hotel.

Friday, July 11. *Morning*: Business Session in the University. Luncheon at the Midland

Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

SATURDAY, JULY 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme is being sent to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

OFFICIAL NOTICE

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

A Member of the Society may purchase a set of Vols. II to VIII inclusive at the reduced price of £2 2s. 6d., and a Non-Member can procure a set at the reduced price of £3 15s., post free in each case.

FORTHCOMING EVENTS

May 26 INSTITUTE OF PHYSICS, Rooms of the Royal Society, Burlington House, Piccadilly, W. 1, at 4.30 p.m. Annual General Meeting. Presidential address by Sir Charles Parsons.

May 26 SOCIETY OF CHEMICAL INDUSTRY, *London Section*. Joint Meeting with the Institution of the Rubber Industry, at the Engineers' Club, 39, Coventry Street, W. 1, at 8 p.m. "Latex: its Chemistry and the Development of its Industrial Applications," by A. Van Rossem. Discussion to be opened by Dr. H. P. Stevens.

May 27 SOCIETY OF GLASS TECHNOLOGY. Joint Conference with the British Society of Master Glass Painters. Annual dinner in the Hotel Cecil.

May 27 ROYAL SOCIETY OF ARTS, at 4.30 p.m. "The Geology and Mineral Resources of Cyprus," by C. G. Cullis, D.Sc.

May 28 ROYAL MICROSCOPICAL SOCIETY, 20, Hanover Square, W. 1, at 7.30 p.m. "Use of the Microscope in the Examination of Paper," by E. Sheldon Leicester. "The Microscopy of Soaps," by K. MacLennan. "Technical Microscopy," by J. E. Barnard.

June 3 ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, 35, Russell Square, W.C. 1, at 7 p.m. "The Analysis of Motion by Kinematography."

June 3 to 6 EMPIRE MINING AND METALLURGICAL CONGRESS, to be held at the British Empire Exhibition. Among other items papers will be read on the following subjects:—Mining, Petroleum, Metallurgy of Iron and Steel, as well as Non-Ferrous Metallurgy.

THE BIOCHEMICAL SOCIETY

A meeting was held in the Department of Physiology, University of Manchester, on May 10, Prof. H. S. Raper in the chair, and the following papers were read:—

"Note on the Constitution of Evodiamine," by Prof. R. Robinson. In spite of observations which were apparently irreconcilable with the view expressed by Kermack, Perkin and Robinson that evodiamine contains the norharman nucleus, it has now been shown by Asahina (*J. Pharm. Soc. Japan*, 1924, No. 503, 1) that this is actually so. Norharman has been obtained from the base and all the difficulties removed by corrections. A considerable number of complex alkaloids may now be recognised as related to tryptophane and this circumstance is regarded as suggestive in connexion with the theory of phytochemical synthesis.

"The Methylation of the Cerebrosides of Ox Brain," by J. Pryde and R. W. Humphreys. The cerebrosides kerasin and phrenosin, isolated from ox brain by Rosenheim's method, may be methylated by means of silver oxide and methyl iodide in a suitable solvent medium. Kerasin yields pentamethyl kerasin, whilst with phrenosin the process is arrested at a stage slightly below that corresponding to a hexamethyl derivative. After hydrolysis of pentamethyl kerasin with dry hydrogen chloride or sulphuric acid in methyl alcohol, the methylated sugar (galactose) residue may be separated by distillation in a high vacuum from the methyl sphingosine and methyl lignocerate. The investigation is being pursued with the view of characterising the constitution of these derivatives, and more particularly that of the sugar residue as it exists *in situ*.

"Chemical Studies of the Vitamin A in Cod-Liver Oil," by Prof. J. C. Drummond and K. H. Coward. Most of the cholesterol may be removed from the unsaponifiable fraction of cod-liver oil by dissolving in methyl alcohol and cooling to −10° C. The remainder is removed by precipitation with digitonin. The cholesterol-free residue is a deep red, heavy oil which contains all the vitamin of the original cod-liver oil. Distillation of this material in superheated steam carries over the vitamin between the temperatures of 115–125° C., together with the bulk of the other constituents, but is useful in separating them from the non-volatile resins formed during saponification. The volatile fraction may be fractionally distilled in high vacuum (1–4 mm.) and yields four main fractions (1) b.p. 100–120° C.; (2) 210–230°; (3) 250–260°; (4) 270–300°. All these fractions contain only carbon, hydrogen and oxygen. Suffering some loss, the main part of the vitamin A comes over with fraction 3. After refractionation the constituents of all four fractions appear to consist mainly of unsaturated alcohols, probably aliphatic in nature, and generally containing two double bonds. There is some indication of the presence of aldehydes also. The vitamin fraction (3) consists mainly of an alcohol with one OH group, two double bonds, and which has a molecular weight about 350, and is optically inactive. There is evidence that this compound is not the

vitamin itself. The latter withstands acetylation, benzoylation and mild hydrogenation of the accompanying alcohol, which may be obtained in the crystalline condition by cooling the methyl alcohol solution to —20° C. These crystals sometimes show physiological activity owing to associated vitamin, and are probably identical with the substance described by Takahashi as the semi-crystalline vitamin. No reliable evidence is yet available to show that the vitamin is an aldehyde, as Takahashi claims, but this view fits in with the scanty data already obtained.

"Supposed Anærobiosis of Lumbricus," by A. D. Ritchie. Earthworms (*Lumbricus sp.*) kept in an atmosphere of hydrogen do not survive more than six or seven hours if kept in movement. At rest about half survive for six hours but none for twenty-four hours. From the bodies of worms exposed to hydrogen for some hours volatile organic acids can be extracted. As the worms' intestines have been found to contain bacteria capable of digesting cellulose, it appears most probable that the accumulation of acid is due to bacterial activity continuing during asphyxia of the worm while it is incapable of oxidising the substances so produced. These experiments dispose of Lesser's contention (*Zeit. Biol.*, 1909, **52**, 282) that earthworms are capable of anærobiosis.

"Supposed Anærobiosis of Ascaris Lumbricoides," by W. K. Slater. As the result of a quantitative investigation of the body content and metabolism products of these parasitic round-worms, Weinland (*Zeit. f. Biol.*, 1901, **43**, 55) suggested that the necessary energy for the various body functions was supplied by the breakdown of carbohydrates under the influence of an enzyme. The products of this reaction are said to be valeric acid, carbon dioxide and hydrogen. The hydrogen was, however, not identified. No oxygen whatever is required by this scheme. The author has found that the "products of metabolism" described by Weinland can be obtained on inoculating glucose solutions with a culture of the bacteria always found associated with the worms, and, further, that when the worms are continuously irritated, those kept under anærobic conditions fatigue more rapidly than those to which the air has access. Worms which have been fatigued in hydrogen recover to some extent if air is subsequently admitted. Experiments have also been tried without definite result in which the air has been replaced by hydrogen acceptors.

"The Oxidation of Stearic Acid with Hydrogen Peroxide," by P. W. Clutterbuck and H. S. Raper. Dakin has shown that oxidation of fatty acids with hydrogen peroxide yields β-keto-acids and ketones corresponding to them. This supports Knoop's theory of β oxidation of fatty acids in the animal body. The authors show that γ oxidation also takes place, γ-ketostearic acid being produced. The relative amounts of the acid undergoing β and γ oxidation are of the order of 7 to 1 respectively; but possibly more γ oxidation takes place than these figures indicate. It seems possible from these results that γ oxidation may also take place in the body. In the course of the investigation, γ hydroxystearic acid, which is supposed to exist only as the lactone (stearolactone), was isolated as a crystalline acid, stable at the ordinary temperature and melting at 88° C. It would seem difficult to account for the occurrence of both β and γ oxidation in terms of electronic structure.

"The Deaminising Action of Tyrosinase," by F. C. Happold and H. S. Raper. The action of potato tyrosinase on various amino acids has been examined, but no evidence has been obtained that ammonia or aldehydes corresponding to the amino acids, are produced. Neither could any change be detected in the amino-nitrogen content of solutions of amino acids subjected to the action of tyrosinase. The amino acids used in the experiments were glycine, alanine, phenylamino-acetic acid, phenylalanine and tyrosine. These results lead the authors to conclude that, contrary to the suggestions of Bach, Chodat and Schweigen, deamination does not play a part in the production of melanin from tyrosine by the enzyme tyrosinase.

"The Excretion of Creatinine and Uric Acid in Man," by H. Zwarenstein. This work was undertaken with the idea that creatinine might arise from some analogous ring compound—from the imidazole nucleus of histidine or the purines—and 4–5 g. of uric acid was given per os to subjects living on purine free diet. In all cases where absorption of uric acid had taken place, an appreciable increase, in one case about 0·5 g., was observed, and it was noted also that in about 90 per cent. of the urines analysed the excretion of uric acid and creatinine varied together. In two experiments ingestion of 1 g. of histidine caused increased excretion of creatinine over a period of three days. These results with uric acid may be due to some action of uric acid on the kidneys, but seem to point to formation of uric acid and to the possibility of creatinine formation from the imidazole nucleus present in some substances.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The general meeting was held in Paris on May 13, under the presidency of Monsieur Paul Kestner. After the President had described the work of the Société during the past year, the financial statement was presented by the Treasurer, and the meeting elected officers for the forthcoming year. As Monsieur Paul Kestner was not elegible for re-election as President, Monsieur Lucien Dior, a manufacturer of fertilisers, was elected to succeed him. The other officers are as follows: Vice-Presidents, MM. Donat Agache, Boyoud, Brangier, Cuvelette, R. Duchemin, R. Etienne, Delage, H. Gall, Léon Levy, R. Masse, C. Matignon and Thesmar; General Secretary, Jean Gerard; Assistant Secretary, Jean Voisin; General Recorder, Maurice Deschiens; Treasurer, Count G. de Germiny; and Librarian, Monsieur A. Job. One-third of the members of the Council were then renewed. Monsieur Maurice Deschiens then proposed that Monsieur Paul Kestner be elected Founder-President of the Société de Chimie Industrielle, a motion adopted with such unanimity and enthusiasm as to show the esteem and affection in which Monsieur Kestner is held.

CHEMICAL SOCIETY

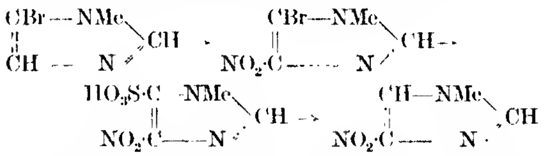
Prof. W. P. Wynne, presiding over an ordinary scientific meeting held on Thursday, May 15, announced that the American Chemical Society had kindly offered to supply copies of their *Chemical Reviews* to Fellows at the reduced price of 4 dollars, plus postage. Commencing with the last issue, no charge was now made to Fellows for binding the Annual Report; money which had been sent for this purpose in error could be reclaimed from the Assistant Secretary before October 31 next, any balance then being placed in the Publications Fund.

Prof. F. L. Pyman contributed a paper (with Mr J. E. Balaban) on:—

The bromo-derivatives of 1-methylglyoxaline and the constitution of "chloroxalmethylin."

4 : 5-*Dibromo-1-methylglyoxaline*, which results from the methylation of 4 : 5-dibromoglyoxaline, is formed in small yield by the bromination of 1-methylglyoxaline, the reduction of 2 : 4 : 5-tribromo-1-methylglyoxaline, or by the interaction of phosphorus pentabromide with dimethyloxamide.

The 4- and 5-bromo-1-methylglyoxalines are obtained simultaneously by the methylation of 4 (or 5)-bromoglyoxaline, the 5 : 1-isomeride predominating. Distillation of the common methiodide of the two bases yields the 4 : 1-isomeride as the main product. The orientation of the bases was effected by converting the 5 : 1-isomeride into the known 4-nitro-1-methylglyoxaline by the operations indicated below:—



By a similar method, Wallach's "chloroxalmethylin" was shown to be 5-chloro-1-methylglyoxaline.

Dr. O. L. Brady, recalling results he had obtained with oximes concerning the influence of the conditions of methylation on the structure of the product, invited further information on this point.

Prof. J. F. Thorpe congratulated the speaker on the advances he had made in the chemistry of glyoxaline; he thought that the present results tended to support his own views, (*a*) that benzene contains no double bond, and (*b*) that glutaconic acid contains a hydrogen atom the position of which is variable.

Prof D R Boyd, referring to the relative ease of hydrolysis of acetyl chloride, methyl chloride, and chlorobenzene, asked whether the phenyl group could be definitely regarded, on the induced polarity theory, as positive.

Prof. Pyman, after remarking that the fundamental work on the constitution of glyoxaline was due to Prof. Japp, said that alkylation was effected with methyl iodide or methyl sulphate in the absence of a solvent; under other conditions, *e.g.*, using diazomethane or alkyl salts and sodium hydroxide, the results would probably be entirely different. His own experience, however, and that of Pinner and Schwarz led him to believe that alkylation by an alkyl salt always took place by addition of the alkyl salt to the doubly linked nitrogen atom. Whilst difficulty was often encountered in determining the polarity of an atom or group, he believed Prof. Lapworth regarded the phenyl group as being positive; support for this view was afforded by comparison of the properties of the derivatives of toluene with those of nitromethane.

Prof. W. N. Haworth gave an account of the

Synthesis of amygdalin. (with R. Campbell)

A SYNTHESIS of amygdalin has been achieved by condensing bromo-hepta-acetylgentiobiose with ethyl d,l-mandelate in presence of silver oxide and conversion of this compound through several stages to the natural glucoside. The product of the above condensation was d,l-hepta-acetylamygdalinic ethyl ester, m.p. 205° and $[\alpha]_D - 62{\cdot}0°$, which was identical in all its properties with a specimen of this substance obtained from amygdalin by esterifying and acetylating amygdalinic acid. Treatment with alcoholic ammonia led to the isolation of a mixture of d- and l-amygdalinic amide, $[\alpha]_D - 77°$, and of its hepta-acetyl derivative, which was resolved, by fractional crystallisation of its additive compound with pyridine, into two stereoisomerides, m.p. 166°—167° and 152°—153°, having $[\alpha]_D - 68{\cdot}6°$ and $- 49{\cdot}7°$ respectively. The former of these gave rise on digesting its solution in xylene with phosphorus pentoxide to needles of hepta-acetylamygdalin m.p. 167° (uncorrected) having $[\alpha]_D - 36{\cdot}2°$. This was identical in all respects with a product obtained by the acetylation of amygdalin and, moreover, the final stage of the removal of the acetyl groups and its conversion into natural amygdalin has already been accomplished by E. Fischer and M. Bergmann (*Ber.*, 1917, **50**, 1066).

Prof. Haworth, who was congratulated by the President and others on the quality of the investigation, added that the *d*-amygdalin had been so called, although it gave rise to *l*-amygdalinic acid on account of its relationship to *d*-malic and *d* tartaric acids.

Mr. R. G. W. Norrish described work (with Dr E. K. Rideal) on:—

Reactivity and radiation. The photochemical union of hydrogen and sulphur.

THE critical increments of eight reactions between hydrogen, sulphur, or oxygen, on the one hand, and sulphur on the other, are all multiples of a constant quantity. This suggests that activation is a quantum phenomenon. It is apparent from the data of previous work that some of the activation of sulphur molecules occurring in these reactions must be kinetic. It is, therefore, of interest to examine them photochemically, with a view to testing how far such activation as is postulated by the "radiation theory" also occurs. The gaseous reaction between hydrogen and sulphur has therefore been investigated, and has been found to be strongly catalysed by the ultra-violet light from the mercury vapour lamp, of the calculated wave length.

The ultraviolet absorption spectrum of sulphur (S_2) vapour has also been reinvestigated and the previous work of Graham confirmed, except that the point of maximum absorption is located very slightly more towards the red end of the spectrum at $\lambda = 2750$ A.U. This wave length corresponds with a critical increment of 51,670 cal. per gram-atom of sulphur, a number in exact agreement with that calculated from the temperature coefficient of the thermal gaseous reaction between hydrogen and sulphur, as required by the radiation theory.

As a result of this work it appears that activation of sulphur molecules may be regarded as synonymous with the dissociation of one or more bonds, and may take place either by collision or by absorption of radiation. The quantity of energy absorbed per atom is independent of the mechanism, and is a function only of the number of valency bonds destroyed.

Dr. Rideal said that a definite example was now available of the stimulation of a chemical action both by thermal collision and by absorption of radiation, the amount of stimulation being in each case the same. Since the nature of the stimulation in each case appeared to be identical, and since photochemical stimulation is usually termed "excitation," it might be advantageous to drop the expression "activation" in this connexion. The similarity between sulphur, chlorine, bromine, and iodine in reaction with hydrogen was likewise evident, the lack of chain reactions in the first case being readily attributable to the difference in the reactions $H_2 + S \rightarrow H_2S$ and $H_2 + Cl \rightarrow HCl + H$. He looked to physicists for information concerning the conditions under which a molecule may be excited, converted into atoms, or ionised by collision with another uncharged molecule. Are the mechanics of collision similar to those of an electron or α-particle bombardment or must such factors as the atomic number or size of the bombarding molecule be considered as well as its *vis viva*?

Mr. W. E. Garner objected to the assumption that the head of an absorption band is the wave length corresponding with the mean energy of activation of hydrogen sulphide. The energy of activation of an individual molecule would depend on its initial vibrational and rotational states: these are quantised and hence there would be a definite number of energies of activation corresponding with the lines in a group of band spectra. Since there might be an unequal distribution of lines on either side of the head of the band, an integration process was necessary for the deduction of the mean activation energy of a gram-molecule from the absorption spectra. The molar activation energy, being the sum of the molecular energies required to raise an electron from an inner to an outer orbit, was necessarily a composite quantity and there was no evidence that it corresponded with the breaking of the chemical bond.

Prof. E. C. C. Baly, did not concur in the view expressed by Mr. W. E. Garner, that the authors' method of calculating the absorption was less trustworthy than the integration of each band. He referred to his own suggestion of the step-activation of molecules and expressed the opinion that the authors had so far discovered "but the germ of a very great truth."

Dr. J. J. Fox said that it was unjustifiable to quote the critical increment to four significant figures; he also felt that to fix on any particular band as the most persistent for any one source of light involved liability to error.

Dr. N. V. Sidgwick said it was remarkable that the energy required to break the double bond in S_2 was exactly twice that required for the single bond in S_8, the behaviour of carbon being very different.

Replying, Mr. Norrish admitted the force of the criticism concerning the critical increment; only the first two figures possessed real significance.

ACADÉMIE DES SCIENCES

On May 12, Prof. Vincent communicated a paper by MM. E. and L. Hedon describing the action of insulin on an animal deprived of its pancreas. Whereas simple ablation of the pancreas brings about death in twenty days, the authors were able to maintain an animal deprived of its pancreas for five months in perfect health, by means of subcutaneous injections of insulin combined with a protein (meat) and carbohydrate diet, to which was added pancreatic ferments.

The influence of the X-rays on the oxydases of leucocytes was described by Prof. D. Berthelot who had found that small doses of X-rays activated, whilst large doses paralysed, the indirect oxydases of the leucocytes.

At the meeting on May 5, Prof. Le Chatelier presented a note by Monsieur Ostwald showing how melted naphthalene can be used to carry out immediate analyses of coal. Gas coal, with 35 per cent. of volatile matter, contains 13 per cent. of materials soluble in naphthalene. The work was carried out in order to obtain a fuel similar to coal which could be coked without leaving an ash. The process was successful, but entailed a large consumption of naphthalene.

Monsieur Coupin observed that green substances growing in the light gave off ozone, suggesting that the greater content of ozone in country air was due to vegetation. Monsieur P. E. Janet communicated the results of work by Monsieur Granier on the conductivity of electrolytes at very high frequencies.

Dr. E. Fox Nichols, director of research in pure science in the Nela Research Laboratory of the General Electric Co., has died suddenly in Washington, D.C. Dr. Nichols was a graduate of Cornell University, and at one time a research student in physics at Cambridge University, and had held professorships of physics at Colgate, Dartmouth, Columbia, and Yale Universities.

CORRESPONDENCE

THE ENGLISH LANGUAGE

SIR,—To Mr. A. E. Johnson, who writes in the March 21 issue, it seems "somewhat of an inversion of the natural order of things that Englishmen should consult the book of an American author in order to learn how to write our common language correctly." Mr. Johnson then administers a gentle rebuke: "The Rev. E. A. Abbott long ago achieved the task attempted by the American writer, by publishing *How to Write Clearly*. From the preface of this Mr. Johnson quotes as follows: "Speeches in Parliament, newspaper narratives and articles, and, above all, resolutions at public meetings, furnish abundant instances of obscurity arising from the monotonous neglect of some dozen rules."

I hold no brief for any particular American book on the subject, but I believe that we on this side of the Atlantic may be credited with contributing to the improvement of good literature; and I feel sure that acquiescence in Mr. Johnson's attitude in regard to overseas effort of this kind is often the cause of lack of sympathy and the development of a peevish antagonism, sentiments that, among educated men, are far more common in England than in the United States.

I feel inclined to disagree with Mr. Johnson's inference that Dr. Abbott's book is sufficient for our needs. The short sentence quoted from the preface is provocative of criticism; "... obscurity arising from ... and ... some dozen ..." Does the author mean a few dozen or several dozen, or about one dozen? Of course, it is easy to assume that the reader possesses a knowledge of the traditional interpretation of localisms in common and accepted use; but scientists and technicians should surely agree (1) that, if possible, words be used in the primary sense, and (2) as to the necessity for simplicity of language, economy of phrasing and unmistakeable clarity in presentation.

The art of technical and scientific composition is not standing still, nor has it been treated adequately by authors of books that purport to tell one how to write clearly or well; we are realising the economic value of condensation and the beauty of simplicity to an extent that was not recognised when Dr. Abbott's book was first published. From the scientific classics of the nineteenth century we still gather much that is inspiring; but from them also we learn much that should be avoided. It is an easy matter for those who profess a disdain of engineering principles and scientific precision, as aids to the building of the edifice of contemporary literature, to turn to the grammar or to the dictionary for a justification of their "style." To-day, however, when competition is keen and production costs are high, additional standards must be recognised. In his *Notes on the Composition of Scientific Papers*, Sir Clifford Allbutt affirms with logic that "Many a bad sentence is grammatically correct"; to which I would add that many a word is listed in the dictionary for use in a specific sense for which it is inappropriate or entirely unsuitable.

In commenting on the preface quoted from *How to Write Clearly*, Mr. Johnson says: "Whether this strong indictment still holds good, I must leave to present-day Members of Parliament, etc., to answer for themselves." The use of etc., although common and accepted as "good English," indicates a lack of precision that mars many scientific and technical articles and books. The reader wonders whether the author was lazy or whether he used the abbreviation to hide a deficiency of information on the subject. I mention this detail to show that finality has not been reached in the art of scientific composition; and I would counter the inevitable charge of being meticulous by the contention that many examples of loose construction are repeated until their use becomes a habit, only because of custom. The plea of justification on the ground of prior and extensive usage in "good" literature is often an illogical one; an obvious disregard of scientific precision and a failure to appreciate the advantages of unmistakeable clarity are sufficient reasons for an "inversion" from what some of us may consider as the "natural order of things."

In the task of improving the technical literature of our day it is to be hoped that the English-speaking nations will act in sympathy with each other. Apart from minor and insignificant differences in spelling and punctuation, the product of the American man of science shows no difference from that of one of his British colleagues. A friendly toleration, if not a generous appreciation, of work overseas is needed to facilitate the acceptance of English as the scientific language of the world; but standards must be based primarily on simplicity, clarity and common sense, rather than on an adherence to habits of phraseology for the continued toleration of which there can be no scientific justification.—I am, Sir, etc.,

Berkeley, California, April 28, 1924. A. W. ALLEN.

ATOMIC STRUCTURE

SIR,—Bearing on my article on "Atomic Structure" (this vol., p. 323), I would like to direct attention to the conclusions inferred by Dauvillier (*Comptes rend.*, 1924, **178**, 476) from his recent determination of the widths of the X-ray spectral absorption bands corresponding to the L_3, L_2, and L_1 energy levels of the gold atom.

The L levels are identified in Bohr's theory with the eight electrons having the total quantum number 2, and are divided into two subgroups of 4 electrons each, having the azimuthal quantum numbers 1 and 2 respectively. I have indicated that the chemical properties of the elements, particularly with regard to valency and co-ordination number, do not lend support to Bohr's scheme, and point definitely to the eight L electrons being in three subgroups containing 2, 2, and 4 electrons, with the azimuthal quantum numbers 1, 1, and 2 respectively, and that in general, the number of electrons in a subgroup is equal to twice the azimuthal quantum number instead of twice the total quantum number.

Dauvillier, accepting that the widths of X-ray spectral absorption bands, are a measure of the relative numbers of the electrons in the groups to which the bands are due, shows that the L level electrons consist of three subgroups closely approximating to the ratio 1 : 1 : 2. There being eight electrons in the level, the numbers in the subgroups are, therefore, 2, 2, and 4, an arrangement identical with that inferred by me from chemical considerations.

In view of the striking agreement between the experimental evidence from both chemistry and physics, there can no longer be any doubt that the L level does not contain two subgroups of 4 electrons each, as postulated by Bohr. It is probable that Bohr inferred his scheme in which the number in a subgroup is equal to twice the total quantum number, from the very imperfect analogy with the 1 quantum group, in which twice the total quantum number gives the correct number of electrons, as in helium, a number accidentally equal to twice the azimuthal quantum number. It may be inferred from Dauvillier's results that Bohr's scheme of equal subgroups is improbable for the electron arrangement in any atom, and, in consequence, that chemical theories based on Bohr's equal subgroup scheme, e.g., the theories based on the invariable co-valent chemical bond, the di-electronic junction necessitating two equal subgroups, are based on an insecure foundation.—I am, Sir, &c.,

CO-OPERATION WITH GERMANY

Sir,—In your journal there have been frequent references to the state of Germany, and the possibility of co-operation. I have been in Germany for some time and have seen many universities here, and to my hand is the third report of the "Notgemeinschaft Deutsche Wissenschaft," a society which organises the relief for universities and educational research institutions. It gives some rather good information on the need of Germany, and whatever may be our opinions on the right and wrong of the war, there can be no doubt that Germany is in great need at present. Happily the Dawes report has dispelled the idea that a large bulk of German capital has been sent abroad. Also it shows how the German capitalists have given relief to their own people, for 5/6ths of the relief is supplied by Germans and 98 per cent. of all the people supported have been supported by German money, and only 2 per cent. by foreign money.

I was in the English Seminar of the Berlin University this morning, and they have a collection of books in English dealing with war matters, in order that they may get to know what the English think about the war. This shows how badly off they are for English and American publications, and scientific and industrial journals, and the number of German scientific and industrial people who see English publications I know to be very small. Travellers in Germany tell of the care with which English books are handled, because of the scarcity of such books.

As a practical method of reaching and bettering industrial matters, may I suggest that more copies of *Chemistry and Industry* be sent to Germany, either to this Society or to private members? I can send addresses of people who would be only too glad to receive them. My own copies of the journal are read with avidity by many students.—I am, Sir, etc.,

THE IMINOTRIAZOLES

Sir,—I have read Dr. Ingold's criticism of our work (Carnelley and Dutt) on Iminotriazoles (this week's *Chemistry and Industry*). I should not like to enter into any discussion in these columns as the paper referred to will soon appear in the Scientific Press. But I may point out that the experimental evidence given in that paper definitely precludes the possibility of Dr. Ingold's interpretation.—I am, Sir, etc.,

P. K. Dutt

IN PRAISE OF LIME

Sir,—I recently visited Wembley, and after a short stay in the Cyprus Pavilion, and experiencing for the first time the famous Cyprus wine, I spent some minutes at the stall of the Buxton Lime Company. The obliging people in charge handed me literature explaining its merits, and as these are not generally known I give them to the best of my recollection:

If your pastures yield Limnaea, in profusion, you may know, vainly you call on Hygeia, soon to death your sheep will go. "Quick my friends and lose no time, oh give them lime."

Regulate acidic ions, soon the pond-snails disappear, liver flukes will then like lions, be rarely found, but here and there. Free from these the sheep will rhyme, "Oh give us lime."

If your lawns are rank with daisies, plantains, yarrow and such weeds, if the clover spreads like blazes, and the grass to language leads, first restore it to its prime by adding lime.

Then the sulphates and the phosphates, nitrates and the potash salts, will act with all the speed of fates, soon the lawn will have no faults. Finest grasses in spring-time, most require lime.

Limestone, thou hast given Gordale, Malham, Haddon Hall and Brough, where from Wales, Nenthead and Yoredale, miners send lead-ore and stuff. Peerless among rocks thou standest, God's boon, Oh Pan and Puck's stone if the purest thou demandest, reputation says Buxton! There the quarries all may climb, admiring lime.

Engineers and concrete makers, iron smelters, road surveyors, tinkers, potters, dukes and bakers, distemper-men and house purveyors, sing in syncopated time, "Oh Buxton lime."—I am, Sir, etc.,

Very Qualified Chemist

Newcastle-on-Tyne
May 17, 1924

[We advise "Very Qualified Chemist" to avoid Cyprus and its products for the future.—Editor.]

PERSONAL AND OTHER ITEMS

Prof Sir Wm H Pope F.R.S., was elected a corresponding member of the Academy of Sciences of the Institut de France at the meeting held on May 12

Dr. A K Macbeth has been appointed Reader in Chemistry in the University of Durham, and Mr. H. J E. Dobson, B.Sc., has been appointed lecturer in chemistry in the same University.

In the University of Manchester, Mr A D. Ritchie, M.A., B.A. has been appointed lecturer in physiological chemistry and the Simon-Carves Industrial Research Scholarship has been awarded to Mr. H. Entwistle B.Sc.

Mr W F. Wyatt has been appointed demonstrator in chemistry in the University of Sheffield

The U.S National Academy of Sciences has awarded its Agassiz medal to O S. Petterson, of Sweden, for his studies on the chemistry and physics of the sea.

Dr. C. M Stine has succeeded Dr C. L. Reese, who has retired from the post of head of the chemical department of E. I. du Pont de Nemours and Co. Dr. Stine has been engaged in research work for the du Pont Co since 1907, and he did valuable work on explosives during the war.

Grants amounting to £175 have been awarded by the Ministry of Agriculture to Sir John Russell, Prof. R C. Punnett, Dr. N. M. Comber, Dr. B. A. Keen, and Mr. G. W. Robinson, to enable them to represent agricultural science in Great Britain at international conferences and congresses

The late Mr. A. F Wenger, the founder of Wengers, chemical manufacturers at Stoke-upon-Trent, left £96,964.

Mr. J W. Leitch, B.Sc., of J. W. Leitch and Co., Milnsbridge, and Lankshear, Wickstead and Co., Ltd., left estate of the gross value of £163,470, with net personalty. £161,383.

The death is announced of Monsieur Bethmont, president of the Société Electro Métallurgie de Dives.

At the recent meeting of the British Empire Steel Corporation the following residents of Great Britain were elected to the directorate:—Sir A. Trevor Dawson, Bart., Rt. Hon. the Viscount Furness, Rt. Hon Lord Invernairn, and Major-Gen. Sir Newton Moore

The death is announced of Mr. T Jamieson, formerly lecturer in agricultural chemistry in the University of Aberdeen, and one of the original fellows of the Institute of Chemistry.

We regret to announce the death, after a short illness, of Mr. Bernard Laporte, chairman and governing director of B. Laporte, Ltd., chemical manufacturers, Luton

Owing to the strong demand for arsenic, for the manufacture of insecticides, the tailing dumps of the Nova Scotia gold mines are being concentrated. Several thousand tons of concentrates, containing about 33 per cent. arsenic and averaging $50 per ton of gold, are ready for transportation from Halifax to Antwerp, Belgium. There are large quantities of tailings available in the vicinity of the old workings of Nova Scotian gold mines.

Sir Archibald Mitchelson, representing the British shareholders of the Porcupine Davidson Co., recently visited the mine whilst in Canada.

Chemists' Meetings in Canada

The annual meeting of the chemists of Canada will take place at Kingston, Ontario, from May 26 to 29 On May 26 the Associate Committee of Chemists of the Advisory Research Council will meet, and several papers will be presented and discussed. The combined sections, in Canada, of the Society of Chemical Industry, will assemble on May 27. Papers will be read and discussed during the day. The annual dinner will take place, in the evening, at the Cataraqui Golf and Country Club, followed by a smoking concert. May 28 will be devoted to the annual meeting of the Canadian Institute of Chemistry At 8 p.m. a public address, upon a chemical topic, will be delivered by Mr. Gilmour, in the Convocation Hall of Queen's University. The last day will consist of visits to the Canadian Locomotive Works, and the Royal Military College with reception by the Commandant, Sir Archibald Macdonell, during the forenoon. The afternoon will be devoted to a tour, by steamer, of the famous Thousand Islands, supper being served at the Isle of Beau Rivage, returning at night to Kingston.

Lawes and Gilbert

In view of the great interest of everything pertaining to the Rothamsted Agricultural Experimental Station, we are glad to reproduce, by permission of the Times Publishing Co., Ltd., the following letter from Sir John Russell, F.R.S., which appeared in *The Times* of May 17.

"It is desired to obtain at Rothamsted as complete as possible a collection of letters of Lawes and Gilbert, the great founders of the Rothamsted Agricultural Experimental Station, and of MSS. relating to Rothamsted itself in the days when they were still in charge here. The purpose is to gather material which can be used for writing a history of their work for the development of agricultural science in general and of British agriculture in particular. My object in writing is to ask if any of your readers having letters by Lawes and Gilbert, or MSS. relating to Rothamsted in its early days, would be good enough to present them to the Rothamsted library, where they will be adequately preserved so that they can be utilised for the purpose indicated above, and, when the task shall be attempted, for the tracing of the history of the development of scientific agriculture."—Sir John Russell, Director of the Rothamsted Experimental Station, Harpenden.

Erratum

In the article on "The Corrosion caused by Products of Combustion of Coal Gas," published in the issue for May 16, on line 9, col. i. of p. 507, for "rust" read "hurt."

REVIEWS

ORGANIC SYNTHESES. Vol. III., edited by H. T. CLARKE and others. Pp. v+104. New York: John Wiley and Sons: London: Chapman and Hall, 1923. Price 7s. 6d.

The third volume of organic preparations, which has now been issued by the indefatigable "editorial board," will, like its predecessors, be warmly welcomed by organic chemists. The object and scope of these volumes is already well known. It is a matter of only too common experience that a large number of preparations, which are copied from original papers into books on practical organic chemistry without being rehearsed in detail, lead to failure, owing in many cases to some small but essential omission. Then, again, the preparation of common organic materials can often be improved by some slight modification of conditions. In these volumes, the contents of which are subject to rigid revision, we have not only methods, but the best available methods for obtaining a given result, and in this way the chemist without ready access to these products may prepare them for himself without waste of time and material or a troublesome search through references.

A collection index of all the preparations so far issued with the number of the volume in which they appear is now being published with each new volume, so that it will be easy to turn to the method required.

The authors again invite co-operation. If this request were generally acceded to, especially on the part of those engaged in industry, a much larger amount of useful material would be forthcoming.

We offer our grateful acknowledgment of the disinterested work so far accomplished and our hope that it will be continued

J. B. COHEN

GRUNDZÜGE DER KOLLOIDLEHRE. By Prof. Dr. HERBERT FREUNDLICH Pp. viii+157. Leipzig Akademische Verlagsgesellschaft, 1924. Price 6 gold marks.

This volume is introduced as an abbreviated version of the author's well-known "Kapillarchemie," designed to appeal to a wider circle of readers than that standard treatise, now in its third edition. It often happens that the author of a large scale volume is so obsessed by the importance of what he has previously written that he is unable to express the essence of the subject in a smaller compass: but there is no trace of that incapacity in the present work. Mathematical deductions, references to literature, and the mass of detail which is calculated to discourage the reader who does not specialise in the subject, have been carefully eliminated, and the result is a charming and useful introduction to the chemistry and physics of colloids.

As in the larger work, the first half of the book, after a stimulating introduction, is devoted to the general properties of surfaces of various kinds, with some emphasis on adsorption and catalytic effects at surfaces. This preliminary matter might make dull reading, if it were not for the illumination of every page by copious examples which indicate the widespread applications of the conclusions summarised. The properties of sols and gels are dealt with in the second half of the book Only a few methods of preparation are given, but the general conditions of stability of sols and the distinctive behaviour of gels are discussed in more detail.

The book is up-to-date in spite of its small size Technical applications are introduced to illustrate the general theme and not relegated to an appendix as is frequently done, and the students of medicine or technology for whom the volume is specially intended will find innumerable points of contact with their own sciences brought out in its pages.

It may be remarked, in conclusion, that the language of the book is remarkably simple throughout, and that the printing and paper, like the price, are of pre-war standard.

P. C. L. THORNE

DAS ERDÖL. By DR. R. KISSLING. Monographien aus dem Gebiete der Fett-Chemie, edited by PROF. K. H. BAUER. Part V. Pp. 146 Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H., 1923.

Unlike its classic namesake by Engler, this volume is of a handy size and deals with the technology of petroleum in four chapters. It is devoid of extraneous matter, padding and elementary treatising so frequently met with in petroleum publications (those in German not excluded). The first chapter deals with the origin and chemical composition of petroleum in 10 pages, its chemical and physical properties in 13, its historical, geographical and geological data in 5, and its winning, storing and transporting in a further five pages Chapter 2, consisting of some 50 pages, deals with all that is important in the refining of crude petroleum in general. Chapter 3, similarly concise, is devoted to the application of petroleum and its products, and Chapter 4 deals with the analysis and testing of petroleum products. In discussing the splitting up of petroleum into its various well-known products, Dr Kissling first gives an outline of the theory underlying the distillation, condensation and chemical treatment of the distillates, and then follows it up with a description of the practical application of the theories, giving details of the apparatus used on works scale. The author finds room also for a short discussion of the methods for treating the oily outflow waters from condensers etc., and spent chemicals from a crude oil refinery. The hints the author gives to refinery superintendents in connexion with refinery processes, plant and general supervision are very practical, and no less valuable are those dealing with fire prevention and fire protection measures, which prove Dr. Kissling to be something more than a writer of technical books. There is a comprehensive name and general index which adds considerably to the value of the book, and altogether this volume should be of practical use to all interested in petroleum, whether professionally or commercially.

J. H. ANFILOGOFF

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Safeguarding of Industries Act (Gas Mantles)

Answering Mr Hogge, Mr Alexander said that he had received a further application from firms in the gas-mantle trade, asking for the appointment of a committee of inquiry under Part II of the Safeguarding of Industries Act, to investigate the new conditions which have arisen as a result of the establishment of German export trade on a gold mark basis; he had now received from the applicants certain supplementary information for which he had asked. The statements made were being carefully considered, and it was hoped that it would be possible to reach a decision at an early date. (May 14.)

COMPANY NEWS

BRUNNER, MOND & CO., LTD.

The net profit for the year ended March 31 amounted to £1,552,574 (against £1,650 295 in the preceding year). With £88,911 brought forward, there is a total of £1,641 485 to be dealt with. The preference dividend takes £300,000, and the dividend for the whole year on the ordinary shares (10½ per cent., less tax, against 11 per cent.) will require £1,016,989. The amount to be placed to the general reserve is £88,015 (against £62,215), while the suspense account receives £150,000 (against £225,000), leaving £86,482 to be carried forward.

ROSARIO NITRATE CO., LTD.

A final dividend is recommended of 6 per cent., less tax, in respect of 1923, making a total distribution for the year of 11 per cent. (against 10 per cent. for the preceding accounting period of 15 months). A sum of £19,671 is to be applied to depreciation, and £29,179 carried forward (against £28,614).

NOBEL INDUSTRIES, LTD.

The directors announce that the results of the constituent and associated companies for 1923 enable them to declare a dividend on the ordinary shares as at July 1, payable on that date, on account of the year 1923 of 8 per cent., less tax. In 1922 the dividend was 7 per cent. It is proposed to increase the special investment reserve account by £160,000 (against £50,000) to £500,000, and to add £140,000 to the balance brought forward, making the total to be carried forward £650,000. The general meeting will be held in September.

CASSEL CYANIDE CO., LTD.

The directors announce that they have resolved to pay an interim dividend of 3d. per share, less income tax at 4s. 6d. in the £. The dividend will be paid on June 2 to all shareholders on the register at May 10, 1924.

LEGAL INTELLIGENCE

NITROLIM AS A FERTILISER

On May 15, in the Commercial Court, King's Bench Division, Mr. Justice Bailhache heard an action by Messrs. Pattullo Higgs and Co., Ltd., of High Street, Orpington, Kent, and Dundee, against the Anglo-Continental Guano Works, Ltd., of Dock House, Billiter Street, E.C., claiming damages for alleged breach of contract and breach of warranty upon the sale of a fertiliser known as granular nitrolim.

For the plaintiff company, it was stated that they purchased some 120 tons of the fertiliser for £1257, believing it contained valuable nitrogen in a form proper and suitable to be mixed with certain other ingredients. They alleged it was not as warranted. The defendant company denied that there was any express warranty or implied warranty and claimed that the fertiliser was in accordance with the contract. They also said they did not know the purposes for which the fertiliser was required, that none of the ingredients in the manure was mentioned, and that there was no implied condition as to its fitness for any particular purpose. Evidence was called on behalf of the plaintiff company in support of their case, and it was also stated that they lost many of their Scottish customers.

At the resumed hearing on May 16 Dr. J. A. Voelcker gave evidence on the results of his analyses of the unmixed granular nitrolim and of the plaintiff company's compound manure mixture. There was nothing, he said, in the constituents which the plaintiffs used to mix with the nitrolim, namely, muriate of potash, precipitated bone, and carbonate of lime, that would produce the chemical body which the plaintiff company said prevented the nitrogen in the nitrolim being readily available for the plants. Mr. L. E. Strong, for the defendant company, expressed the opinion that the mixture in question was unsuited for potato crops. Further evidence was called, and hearing adjourned until May 19, when it was argued for the plaintiff company that the substance contracted to be sold was a nitrogen fertiliser whose nitrogen was readily available, but the stuff supplied was not that. It was contended that the plaintiffs' evidence established that the nitrogen was not available in the material, and that the stuff did not work as a nitrogenous fertiliser should do. The evidence called for the defendants did not displace that.

Mr. Justice Bailhache, in giving judgment, said that the plaintiffs contended that whatever the mixture was the nitrogen should have shown itself in the early stage of plant development. There was no suggestion that anything in the mixture prevented the operation of the granular nitrolim. On the whole, he had come to the conclusion that in the nitrolim delivered to plaintiffs the nitrogen was not in a form which could be readily assimilated by plants. Therefore as plaintiffs did not get what they paid for, they were entitled to a return of the purchase price, less the value of the lime which the nitrolim contained. There would be judgment for plaintiffs for £1155 and costs.

In another case the Anglo-Continental Guano Works, Ltd., sued Nitrogen Fertilisers, Ltd., for damages in respect of sales to them of granular nitrolim in alleged breach of representations or warranties contained in pamphlets or leaflets. The plaintiffs claimed to be entitled to be indemnified for damages for which they had been held liable. Mr. Justice Bailhache said that the plaintiffs' principal witness said he did not rely on the pamphlets and leaflets, and another difficulty was in fact that the 120 tons of nitrolim in this case had been kept from one to two years. It deteriorated by keeping, and having regard to the fact that some thousands of tons of the nitrolim had been sold and no complaint made, he thought there must have been something specially wrong with this 120 tons. In the circumstances he could not pass on to the defendants the damages which the Anglo-Continental Guano Co., Ltd., had been ordered to pay, and judgment must be returned for defendants, with costs

REPORTS

Report on the Commercial, Industrial, and Economic Situation in Italy, December, 1923. By J. H. Henderson and H. C. A. Carpenter, Commercial Secretaries, Rome. Department of Overseas Trade. Pp. 96. H.M. Stationery Office, 1924. Price 2s. 6d. net.

Great strides have been made by the Government in 1923 in establishing a strong economic position for the country. An extended and more strictly enforced system of taxation has been put into force, and economies effected all round in administration costs. The exchange is now stable and the balance of trade (in the widest sense) is believed to be favourable.

Complete figures for 1922 show imports valued at 15,770·38 million lire, and exports at 9,297 mill. lire, the adverse balance being about 2500 mill. lire more than in 1921 (*cf. Chem. and Ind.*, 1923, 662). The figures for the first half of 1923 show imports 9073 mill. lire, and exports 4887 mill. lire; both show an increase over the corresponding figures for 1922, but a larger adverse balance.

The country with the biggest trade with Italy is the United States, Great Britain doing about half as much. In the first six months of 1923 imports from this country amounted to 1147 mill. lire, and exports to 561 mill. lire. The principal items obtained from Great Britain are coal, textiles, machinery, iron and steel, and fish, which together make up 80 per cent. of the total. Demands for coal from this country have been affected in recent years by the supplies from Germany as reparations. The textile trade in 1923 was satisfactory. There is a considerable demand for British heavy chemicals, such as caustic soda, sodium bicarbonate, copper sulphate and ammonium sulphate; other chemicals are supplies by Jugoslavia, Germany, and the United States. British paints and varnishes are in demand, but now have to meet local competition. The market for British earthenware, china and glass is restricted, only the best qualities being able to compete in this market.

Italian industries suffered in 1923 from the universal depression, an improvement being noticeable as the year advanced. The silk industry, the principal manufacturing industry in the country, had a good year, whilst other textiles also showed some improvement; artificial silk manufacture has recently become important. The chemical industry presents a normal aspect. Superphosphates have done well, owing to increased home demand, and the manufacture of dyes and soaps increased during the year.

Report on the Trade and Commerce of East Africa, to September, 1923. By Col. W. H. Franklin, C.B.E., D.S.O., H.M. Trade Commissioner, E. Africa. Department of Overseas Trade. Pp. 46. H.M. Stationery Office, 1924. Price 1s. 6d.

The statistics given in this report cover in detail the year ending December 31, 1922, though a few figures are available for the six months following. Exports are increasing and the political situation has improved since the statement of the Imperial Government's policy regarding the Indian community. Coastal exports in 1922 amounted to £9,736,862, and imports to £9,230,849. Exports of cotton from Uganda in 1922 were 61,641 bales, in the first six months of 1923, 62,700 bales. Tanganyika Territory and Kenya Colony also exported cotton to a relatively small extent. Coffee exports from Kenya and Uganda in 1922 were 129,261 cwt., and from Tanganyika, 85,428 cwt., considerably more than in 1921; there is a general increase in the acreage put under coffee. The period under review has witnessed the clearing of old stocks of skins and hides, though the market has now quietened, owing to cessation of demands from Europe and America. Small parcels of Uganda Para rubber have been disposed of, and planters have been encouraged to resume tapping; for the Ceara of Tanganyika Territory, however, there is but small demand, and production seems likely to cease. Zanzibar is an important collecting station for copra, of which about 12,500 tons are exported annually. A notable increase has occurred in the export of oilseeds; about 8000 t. of cotton seeds was exported from Uganda in the first six months of 1923, against 2440 t. in 1922, and 12,518 t. of ground nuts were exported from Tanganyika in 1922, against 8448 t. the previous year. Exports of Magadi soda practically ceased last April, and are not likely to be recommenced until the reconstruction of the company. Some prospecting for minerals, mentioned in the last report (*cf. Chem. and Ind.*, 1923, 281) is still going on, and a promising gold-bearing seam has been discovered. The exports of mica from Tanganyika are increasing.

Of the imports into the area cotton piece goods form about one-third. About 10,000 t. of cement were imported in 1922, Norwegian competition being strong, whilst in china and glassware Germany is a serious rival to Great Britain. The United Kingdom predominates as supplier of iron and steel goods, but European competition is strong here also.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton
Ammonia Alkali	£6 15s. per ton, spot, delivery.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2 cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1 cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite. 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£5 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	43s. 6d. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	5s. 1d. per lb. Much dearer, following rise in quicksilver.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s.—5s. 3d. per gall. 60% O.P. market stiffer.
Solvent	5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£49 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7d. per lb. Better inquiry at reduced price.
Crude 60's	1s. 10d.—2s. per gall. Market rather flat.
Acid Cresylic, 97/99	2s. 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d. per gall. Very quiet
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall ex works in tank wagons.
Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Pure	1s. 10d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9½d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	7½d.—9d. per gall. according to grade and district. Market easier.

Naphtha—	
Crude	.. 8d.—9d. per gall. } Good demand. Prices firm.
Solvent 90/160	.. 1s. 5d.—1s. 6d.
Solvent 90/190	.. 1s. 2d.—1s. 3d.
Naphthalene Crude—	
Drained Creosote Salts	£6—£7 10s. Demand falling off.
Whizzed or hot pressed	£9 –£12 per ton. More inquiry.
Naphthalene—	
Crystals and Flaked	.. £17– £18 per ton.
Pitch, medium soft	.. 52s. 6d. –57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt.
Pyridine –90/140	.. 22s.—24s. per gall. Demand well maintained.
Heavy	.. 11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

Business in dyestuffs has fallen off considerably in all branches, and the position is not so favourable as it was. Prices are without alteration.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 6d. per lb.
Acid H.	.. 4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 3d. per lb. Steady demand.
Acid Sulphanilic	.. 10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	.. 1s. per lb. d/d.
Aniline Oil ..	.. 7¾d. –8¼d. per lb. naked at works.
Aniline Salts ..	.. 7¾d.– 9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 3d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o Cresol 19/31° C.	.. 4¾d.– –5¼d. per lb. Demand moderate.
m Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb Demand moderate.
p Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £75 per ton.
Diethylaniline ..	.. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline ..	.. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 3s. 1d. per lb. d/d.
Monochlorbenzol..	.. £63 per ton.
β Naphthol ..	.. 1s. 1d. per lb. d/d.
α Naphthylamine	.. 1s. 4½d. per lb. d/d.
β Naphthylamine	.. 4s. per lb. d/d.
m Nitraniline ..	.. 5s. 3d. per lb. d/d.
p Nitraniline ..	.. 2s. 4d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 11¾d. per lb. d/d.
p Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m Phenylene Diamine	.. 4s. 2d. per lb. d/d.
p Phenylene Diamine	.. 10s. 4d. per lb. 100% basis d/d.
R Salt	.. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 6d. per lb. 100% basis d/d.
o Toluidine ..	.. 8½d. per lb.
p-Toluidine ..	.. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £49 per ton.
Acid, Acetyl Salicylic	.. 3s. 4d.– 3s. 5d. per lb. Market rather quiet. Low offers are being made from the Continent.
Acid, Benzoic B.P.	.. 3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P.	.. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst.	.. 7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic ..	.. Prices quoted from 2s. 2d. per lb. down to 1s. 11d. for ton lots. Market rather firmer.
Acid, Tannic B.P.	.. 3s. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 3d. per lb. for quantity. Easier market.
Amidopyrin .	.. 13s. 6d per lb Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. per oz. for English make.
Barbitone..	15s 6d per lb. Quiet market.
Benzonaphthol .	. 5s 6d per lb. Small inquiry.
Bismuth Salts ..	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
,, Citrate ..	.. 11s. 4d.—13s. 4d. ,,
,, Salicylate	.. 10s. 2d.—12s. 2d. ,,
,, Subnitrate	.. 10s. 9d.—12s. 9d. ,,
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides - ..	.. Market easier.
Potassium ..	.. 9½d.—10d. per lb.
Sodium ..	.. 9½d.—10d. ,,
Ammonium	.. 10½d. 11d. ,,
Calcium Lactate	.. Demand not very active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate ..	.. 3s. 9d. per lb.
Chloroform .	.. 2s. per lb. for cwt. lots. Market more active. Makers busy.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde .	.. £57 per ton, ex works. English make.
Guaiacol Carbonate	.. 12s. per lb. for cwt. lots. Supplies not plentiful.
Hexamine .	.. 3s. 6d. per lb. for English make. Imports cannot be made at this figure.
Homatropine Hydrobromide	.. 30s. per oz.
Hydroquinone ..	.. 4s. 9d. per lb. Foreign make.
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.

Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	70s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Market rather flat, but prices unchanged.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	2s. 3d.—2s. 9d. per lb. for carboys. A slightly better market
Methyl Sulphonal	25s. per lb. No demand
Metol	11s. per lb. British make
Paraformaldehyde	3s. 6d. per lb. Better inquiry.
Paraldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand
Phenacetin	6s. per lb. Somewhat cheaper.
Phenazone	7s. 9d. per lb. for cwt. lots. Quiet
Phenolphthalein	6s. 9d.—7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal	8¾d.—9d. per lb. carriage paid.
Commercial	8d.—8¼d. per lb. carriage paid.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Saccharin	63s. per lb., in 50-lb. lots
Salol	4s. per lb. Very quiet.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. In steady demand for good qualities.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—	
Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1 cwt. kegs.
Sod. Metabisulphite cryst	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity
Sod. Potass. Tartrate (Rochelle Salt)	77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet
Sod. Salicylate	Market easier. Powder 2s. 4d.—2s. 6d. per lb. Crystal at 2s. 6d.—2s. 8d. per lb. Flake 2s. 9d.—3s. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity. 1-cwt. kegs included. In large casks £1 per ton less
Sulphonal	17s. per lb.
Tartar Emetic	1s. 4d. per lb. for cwt. lots.
Thymol	14s.—15s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	14s. 6d. per lb.	
Amyl Acetate	2s. 9d. ,,	
Amyl Butyrate	7s. 3d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,	
Benzyl Alcohol free from Chlorine	3s. 3d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde Natural	15s. 6d. ,,	
Coumarin	20s. ,,	
Citronellol	16s. ,,	
Citral	10s. ,,	
Ethyl Cinnamate	15s. ,,	
Ethyl Phthalate	3s. 3d. ,,	Reduced.
Eugenol	11s. ,,	
Geraniol (Palmarosa)	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	
Heliotropine	6s. 6d. per lb.	Reduced.
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose	28s. 6d. ,,	Reduced
Linalyl Acetate	28s. 6d. ,,	Reduced
Methyl Anthranilate	9s. 6d. ,,	
Methyl Benzoate	6s. ,,	
Musk Ambrette	48s. 6d. ,,	Reduced.
Musk Xylol	16s. 6d. ,,	Reduced.
Nerolin	4s. ,,	
Phenyl Ethyl Acetate	12s. 6d. ,,	
Phenyl Ethyl Alcohol	16s. ,,	
Rhodinol	57s. 6d. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 9d. ,,	
Vanillin	25s. 3d.—26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	3s. per lb.	
Bergamot Oil	18s. 6d. per lb.	
Bourbon Geranium Oil	36s. 6d. ,,	Advanced
Camphor Oil	75s. per cwt.	
Cananga Oil, Java	10s. 6d. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Cassia Oil, 80/85%	9s. 3d. per lb.	
Citronella Oil—		
Java 85/90%	5s. 9d. per lb.	Again dearer.
Ceylon	3s. 9d. ,,	
Clove Oil	8s. 3d. ,,	
Eucalyptus Oil 70/75%	2s. 2d. ,,	
Lavender Oil—		
French 38/40% Esters	62s. per lb.	
Lemon Oil	3s. 2d. per lb.	
Lemongrass Oil	3d. per oz.	
Orange Oil, Sweet	13s. 9d. per lb.	
Otto of Rose Oil—		
Bulgarian	27s. 6d. per oz.	
Anatolian	23s. 6d. per oz.	
Palma Rosa Oil	19s. per lb.	
Peppermint Oil—		
Wayne County	21s. 9d. per lb.	
Japanese	18s. 3d. per lb.	
Petitgrain Oil	10s. per lb.	
Sandal Wood Oil—		
Mysore	26s. 6d. per lb.	
Australian	21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents, those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 14th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. on May 29th.

I.—Applications

Barratt and Greaves. 11,135. See VII.

Boormann. Counter-current columns for separating or washing fluids. 11,539. May 9.

Craig, Shawfield, and Lever Bros. Distillation etc. plants. 11,530–31. May 9.

De Laval Chadburn Co., Ltd. (Aktiebolaget Separator). Separators. 11,521. May 9.

Hadlington and Washington. Reverberatory furnaces. 11,162. May 6.

Hanley. Film evaporators. 11,334. May 7.

Herrmann Ges. Filtering liquids. 11,104. May 5. (Ger., 23.5.23.)

Honigmann. Annular furnaces. 11,513. May 9.

O'Donovan. Heat treatment of materials. 11,179. May 6. (Union of S. Africa, 25.1.24.)

Procter. Apparatus for drying granular etc. materials. 11,306. May 8.

Sears. Furnaces. 11,251. May 7.

I.—Complete Specifications Accepted

2816 (1923). Hughes (Schmidt). Distillation installations, solvent recovery plants, etc. (215,073.)

3171 (1923). Iondes, Ransomes and Rapier, Ltd. Mixing machines. (215,093.)

21,851 (1923). Gettings and Bodman. Mixing-apparatus. (215,261.)

II.—Applications

Badische Anilin and Soda Fabrik. Fuel for internal combustion engines. 11,131. May 8. (Ger., 2.7.23.)

Banner. Manufacture of an emulsion of oil and water. 11,589. May 10.

Barratt and Greaves. 11,135. See VII.

Draabl. Drying peats etc. 11,572. May 10.

Koppers Coke Oven Co., Ltd. Vertical retorts for distilling fuel. 11,187. May 6. (Ger., 7.5.23.)

Lo Branchez. Internal distillation of combustibles. 10,995. May 5.

Nagel. Briquettes. 11,072. May 5.

Nagel. Binding fuel materials. 11,073. May 5.

Pase (Brégeat). Process of treating motor spirit etc. 11,471. May 9.

Potts (Algemeene Norit Maatschappij). Production of active carbons. 11,451. May 9.

Sauer. Production and revivification of activated carbon. 11,463. May 9.

Schwarz. Purifying mineral oil products etc. 11,532. May 9.

Shaw. 11,011. See IX.

II.—Complete Specifications Accepted

2411 (1923). Lamplough and Fathers. Manufacture of fuel briquettes. (215,056.)

2782 (1923). Jackson (Western Gas Construction Co.) Apparatus for the manufacture of gas. (215,069.)

3538 (1923). Koppers Co. Treatment of ammonia-charged gas. (209,379.)

3546 (1923). Koppers Co. Removal of hydrogen sulphide etc. from gases. (210,382.)

5819 (1924). Lamplough and Fathers. Manufacture of fuel briquettes. (215,292.)

IV.—Applications

Eckermann, Steinbuch, and Soc. Chem. Ind. in Basle. Condensation products of the anthraquinone series. 11,219. May 6.

British Alizarine Co., Ltd., Anderson, and Dawson. Manufacture of dyestuffs and intermediates. 11,137. May 6.

Evans. Sheet-delivery mechanism of printing machines. 11,418. May 8.

Farbenfabriken vorm. F. Bayer und Co. Manufacture of azo dyestuffs. 11,322. May 7. (Ger., 7.5.23.)

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of dyestuffs. 11,540. May 9. (Ger., 9.5.23.)

Imray (Soc. of Chem. Ind. in Basle). Manufacture of dyestuffs etc. 11,439–40. May 8.

IV.—Complete Specifications Accepted

4287 (1923). Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of azo-dyestuffs. (193,831.)

30,838 (1923). Durand und Huguenin Akt.-Ges. Manufacture of disazo dyestuffs. (208,162.)

V.—Applications

Karplus. Treatment of artificial silk. 11,116. May 5.

Lindsay. Cellulose compositions. 11,107–8. May 5.

Newby. 11,324–5. See XIII.

V.—Complete Specifications Accepted

30,211 (1922). Dreaper. Manufacture of artificial silk etc. from viscose solutions. (215,028.)

14,154 (1923). Soc. Seta Artificiale di Padova. Treating artificial filaments. (198,673.)

VI.—Applications

British Alizarine Co., Ltd., Dawson, and Wilson. Printing fabrics and composition therefor. 11,138. May 6.

Farbenfabriken vorm. F. Bayer und Co. Process for dyeing acetate silk. 11,545. May 9. (Ger., 9.5.23.)

Hall, and Silver Springs Bleaching and Dyeing Co. Dyeing black shades on cellulose-acetate fibres, films, etc. 11,169. May 9.

Hall, and Silver Springs Bleaching and Dyeing Co. Dyeing aniline black on textile materials. 11,170. May 9.

VI.—Complete Specification Accepted

2593 (1923). Brandwood. Apparatus for dyeing, bleaching, scouring, mercerising, etc. (215,064.)

VII.—Applications

Barratt and Greaves. Apparatus for distilling ammonia liquor, washing gases, etc. 11,135. May 6.

Bernard. 11,615. See XVI.

Goldschmidt Akt.-Ges. Production of sulphur. 11,032. May 5. (Ger., 16.8.23.)

Neill. Heat process of manufacturing ferric oxide. 11,036. May 5. (Australia, 12.3.24.)

Planchon. Production of lead acetate. 11,609. May 10. (Ger., 30.10.23.)

Smith. Conversion of lead sulphate into lead carbonate. 11,409. May 5.

VIII.—Application

Soc. Anon. Quartz et Silice. Manufacture of silica glass articles. 11,039, 11,040. May 5. (Fr., 2.11.23.)

VIII.—Complete Specification Accepted

14,173 (1923). Marks (Roth A.-G.). Preparation of clay etc. for moulding. (215,207.)

IX.—Applications

Bloxam (Holzapfel). Preservation of wood. 11,220. May 6.

Dickins. Waterproofing cement. 11,067. May 5.

Girouard. Treatment of calcareous cement etc. 11,019. May 5.

Mulligan. Plaster. 11,399, 11,483. May 8 and 9.

Shaw. Production of coloured bituminous emulsions. 11,011. May 5.

X.—Applications

Durant and Rhodes. Treatment of ores, concentrates, etc. 11,421. May 8.

Kilby and Spalton. Manufacture and refining of steel. 11,209. May 6.

Minerals Separation, Ltd. Concentration of ores. 11,215. May 6. (U.S., 23.10.23.)

X.—Complete Specifications Accepted

29,272 (1922). Reis. Treatment of metals to render them harder and rustproof. (214,872.)

404 and 7870 (1923). Morgan. Manufacture of wrought iron. (215,049.)

2547 (1923). Metallbank u. Metallurgische Ges. Increasing the electric conductivity of alloys. (192,414.)

19,742 (1923). British Thomson Houston Co. (General Electric Co.). Alloys. (215,231.)

21,006 (1923). Morgan. Manufacture of wrought iron by piling. (215,212.)

XI.—Application

Soc. Anon. Le Carbone. Galvanic batteries. 11,227. May 6. (Fr., 10.1.24.)

XI.—Complete Specification Accepted

29,175 (1923). Metropolitan Vickers Electrical Co., Ltd. Electric furnaces. (207,804.)

XII. Applications

Banner. 11,589. See II.

Flockton. Extracting oil from palm fruit. 11,159. May 6.

XII. Complete Specification Accepted

3672 (1923). Marks (Nield). Apparatus for extracting oil, fats, and waxes. (215,113.)

XIII.—Applications

Caughlin. Printing ink. 11,037. May 5.

Newby. Cellulose acetate varnishes. 11,324, 11,325. May 7.

XIII. Complete Specifications Accepted

9522 (1923). Bakelite Ges., and Hessen. Manufacture of condensation products from phenols and formaldehyde. (206,169.)

17,239 (1923). Shimadzu. Paint. (215,222.)

19,175 (1923). Soc. of Chem. Ind. in Basle. Manufacture of resins. (203,340.)

XIV.—Complete Specifications Accepted

3514 (1923). Naugatuck Chemical Co. Vulcanisation of rubber. (200,789.)

19,311 (1923). Chatelain. Vulcanisation of caoutchouc etc. (201,570.)

XV. Application

Luttig and Schmid. Treatment of hides and skins. 11,064. May 5.

XVI. Applications

Bernard. Process for enrichment etc. of phosphated chalk etc. 11,615. May 10.

Hiller. Manufacture of meal for fertilising etc. 11,303. May 7. (U.S., 7.5.23.)

XVII.—Complete Specification Accepted

13,892 (1923). Smer. Purifying and decolorising sugar solutions. (198,374.)

XVIII. Complete Specification Accepted

13,860 (1923). Boby and Griffiths. Production of grist for brewing etc. (215,202.)

XIX. Applications

Hoyberg. Process for making butter. 11,328. May 7.

Mond (Chemische Fabrik Griesheim-Elektron). Utilisation of nutrient-containing shells. 11,415. May 8.

XIX.—Complete Specification Accepted

34,757 (1922). Gates. Production of milk foods. (215,039.)

20,305 (1923). Girard. Apparatus for treating sewage and like liquids. (215,237.)

XX.—Applications

Bonhôte, Montmollin, and Soc. Chem. Ind. in Basle. Manufacture of aryloxynaphthyl-ketones. 11,326. May 7.

Lockemann. Manufacture of 1-phenyl-2.3-dimethyl-4-dimethylamino-5-pyrazolone. 11,614. May 10. (Ger. 11.10.23.)

Mallinckrodt. Rendering ether air-free. 11,033. May 5.

Soc. Lefranc et Cie. Manufacture of ketones. 11,402. May 8. (Fr., 17.5.23.)

XX.—Complete Specification Accepted

25,478 (1923). Hoffmann-La Roche und Co. Akt.-Ges. Manufacture of emulsions of bismuth salts. (206,487.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Argentina*: Rubberred cloth (567); *Australia*: Cutlery (532), hardware (533), leather (Official Secretary, Commercial Bureau, Australia House, Strand, W.C. 2. Ref. Com. 412/7/1/1/239); *Bolivia*: Paints (884/22/F.G./C.C./2); *Brazil*: Leather, paper, iron and steel (569); *British India*: Paint (The Director General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *Canada*: Lead pipe (13,624/E.D./E.C./2); *Cuba*: Hardware (572); *Denmark*: Industrial chemicals, anti-rust paint (541); *Guatemala*: Chinaware, cutlery, leather (574); *Hayti*: Shellac (9789/F.L./C.C./2); *Italy*: Silk (547); *Netherlands*: Cutlery (550), leather (551), silk (552); *New Zealand*: Artificial silk (538); *Poland*: Leather (554); *South Africa*: Hides (12,339/E.D./M.C. 2), copper tubes (12,225/E.D./E.C./A.); *Turkey*: Tin, ammonia, zinc, tinplate (561), petrol and crude petroleum-driven engines (563); *United States*: Steel and bronze (22,834/F.W./E.C./2); *Yugoslavia*: Tin, tinplate (555).

Trade Information

Tully Gas Plants, Ltd., have announced that consequent upon their amalgamation with Gas and Fuel Plants, Ltd., the company has gone into voluntary liquidation. The business will, in future, be carried on by Gas and Fuel Plants, Ltd., who own construction rights for plants for the production of smokeless fuel. The registered office of Gas and Fuel Plants, Ltd., is 40/3, Norfolk Street, Strand, London, W.C. 2; the telegraphic address is "Damper, Estrand, London," and the telephone numbers are City 4047 and 4048.

Italian Company News

The capital of the Società Italiana Prodotti Azotati is to be increased from 9 to 20 million lire, and that of the Società Industria Concimi ed Affini is to be raised from 600,000 to 2 million lire.

PUBLICATIONS RECEIVED

LIME AND MAGNESIA. THE CHEMISTRY, MANUFACTURE AND USES OF THE OXIDES, HYDROXIDES, AND CARBONATES OF CALCIUM AND MAGNESIUM. By N. V. S. Knibbs, B.Sc. Pp. 306. London: Ernest Benn, Ltd., 1924. Price 30s.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES | LONDON, MAY 30, 1924 | No. 22

EDITORIAL

THE letters from Mr. Pickard and Pedant on the English language call attention to a point of which we were ignorant, that Mr Rickard is English in his origin and education We are always glad to be corrected or supplied with additional information on topics which we have dealt with in these columns. It is at least evidence that the editorials are perused; many important and interesting facts have been given to our readers by correspondents to this *Journal* and we are glad to have the opportunity of expressing our gratitude to this numerous body. Those who make corrections to chemical articles, even to such ephemeral matter as editorials in a weekly journal, are helping to maintain a higher standard of accuracy. Editorials are usually written hurriedly and they are not intended to be of interest except for the few moments of perusal. They are hardly more than hors d'oeuvres; like these, they are a habit, a convention, and those who wish to proceed rapidly to the more solid and satisfying parts can easily spend the few minutes involved in a more profitable manner. It is accepted by all connected with journals that the correspondence columns have a quite different character; they are frequently the first to be read; they bring out new points and fresh ideas. It has surprised us that we have received so few letters from chemists about that project which is now receiving attention from a small committee but should be of interest to so many chemists, we mean of course, Chemistry House. Those we meet and talk to on the subject are enthusiastic and determined to make the project a success; we sometimes wonder whether they are representative. What do the majority think about the project? Perhaps it would be more pertinent, though less polite, to enquire whether they do think about it. When chemists have finished their arduous day's work, their tennis and their gardening, do they as the light gradually fades away, sit and think, or do they just sit?

* * *

We thought a fortnight ago that we had, for the time, finished with the War and the difference between the views of the French and Germans. Dr. Fritzsche, who writes us a further letter, has claimed to make public the views of the average German man of science; no other German has dissented from his statement, and we are entitled therefore to accept his claim. We cannot fill our columns with history and politics, and if Dr. Fritzsche had been of any other nationality we should have thought that his letter was not suitable for publication in them. But as we felt sure that to refuse to publish his letter would lay ourselves open to a suspicion of partiality we have inserted it A few days ago we read with care a great deal of the diplomatic correspondence officially published by Great Britain and by France, and also the whole of Prince Lichnowsky's Memoir. We are bound to say that many of the distinguished German statesmen who were most intimately concerned did not, so far as can be judged by the letters and memoranda written by them in June and July, 1914, hold the views which Dr Fritzsche now holds. We have no intention of mentioning in detail those statements of his which appear to us to conflict with the official statements made by the German Chancellor, Ambassadors and other important personages who might be supposed to be well acquainted with the facts. If we thought any useful purpose would be served we should be willing to discuss these matters in detail, giving chapter and verse for our arguments; but not in this

journal. *Chemistry and Industry* deals with chemistry and not history; for this reason and this reason alone we must in future refuse to publish accounts, whether they seem to us to be accurate or inaccurate, of the causes of the War. It is another matter to consider such questions as the policy of the Union Internationale; this is a question in which chemists are primarily concerned, and if our readers choose to write on this topic there is obviously no objection, subject to the qualification we have already mentioned. We are grateful to Dr. Fritzsche for his letters and interested to know what his views are; we should have been more pleased had they not been so different from those current in this country, but we cannot help this difference, nor is this the place to explain it.

* * *

How would Dr. Johnson have defined the word "photography" had this been in use at the time of his Dictionary? Seventy years ago he would have dismissed it possibly as an "occupation for light minds," but one could well imagine his absorption had he been able to read, on his way to Lichfield, not Bishop Watson, but Prof. Bancroft's reprint of his contribution to the discussion held by the Faraday Society on the physical chemistry of the photographic process, the articles on photography by Sir W. J. Pope and Mr. W. Clark in "Chemistry in the Twentieth Century," and that excellent little booklet, "Foresight in Photography" (published by Burroughs Wellcome and Co.), which is noticed elsewhere in this issue. One does not know which to admire most: Prof. Bancroft for his clear exposition of the lacunæ in photographic theory; Sir William Pope and Mr Clark for their insistence on the value of photography as a scientific instrument and the promise of its future; or the booklet "Foresight" for its able advocacy of the use of sound methods as an insurance for success. Prof. Bancroft says "the theory of the photographic emulsion is very much up in the air." Says Mr. Clark, "the 'emulsion' is in reality a 'suspension' of fine crystalline particles of silver halide in a medium of gelatin, or in certain cases, of collodion." Sir William Pope observes that "in a few years' time no one will tolerate the ordinary photographic portrait, with its false rendering in monochrome of colour values." It is to be feared we know little about gelatin or about silver halides, though the British Photographic Research Association is doing excellent work in bringing light into our darkness, and we can expect still more. But Sir William Pope has earned the gratitude of every user of photographic plates by his work on colour sensitisers and desensitisers, so we must not blame the chemist for the faulty tone renderings shown in our counterfeit presentments. And while we are waiting for the perfect plate, Burroughs Wellcome are here to show us how to make the best of what we have.

* * *

The gas industry always seems so young and vigorous that it is almost surprising to learn that the centenary of the lighting of Paris by gas is being celebrated this week. And what an outcry there was against the introduction of such a pernicious invention! It was sure to cause blindness and diseases of the lungs, people would be asphyxiated, and fires would break out everywhere. Every innovation, however useful, seems foredoomed to bitter, if futile, opposition, and the gas industry throughout its triumphant career, has never lacked its critics, even to the days of the therm. The heathen ever find cause furiously to rage, whether at spinning jennies or at steam engines. It is not so long since a steam roller had to be preceded by a varlet bearing a red flag, and there are still people who would like every industry to be neatly tagged with red flags. But it is all very good for industry, especially for British industry, which is apt to reveal unexpected qualities when there is really need, as we learnt so thoroughly during the war. The gas industry is no exception, and although the introduction of electric lighting about 1883 found the industry "trudging along in a more or less lethargic manner," very soon the pace was not lacking in vivacity. Indeed, the opponents were finally reduced to calling the gas industry "effete." It is true that the gas industry still has a very great deal to learn about its raw material, coal, but then one is told that the efficiency of electrical generation by means of coal heating is not all that could be desired. Both industries have their place, and no doubt in time they will become platonic, if not bosom friends. One does not always realise the magnitude of the gas industry, however, and it is of interest to recall that the chairman of the Gas Light and Coke Company recently stated that his company produces annually as much energy in heat, light and power as is produced by the whole of the electrical undertakings in Great Britain, and that the increased consumption (10 per cent.) of the company's gas during the first quarter of 1924 is equivalent, in electrical heat units, to 250 million kilowatt hours, or, roughly, the annual consumption of current in Birmingham and Sheffield.

* * *

The centenary of gas lighting in Paris recalls the controversy about the actual originator of the process. It is usually stated that William Murdoch first used coal gas as an illuminant about 1792, whilst Lord Dundonald used it for lighting Culross Abbey in 1782, Prof. J. P. Minckelers lighted his lecture theatre in Louvain with gas in 1785, and Philippe Lebon, to whose plans the first illumination of Paris with gas was due, took out a patent in 1799. It seems unlikely that gas manufacture arose independently any more than do other discoveries, for it is certain that the production of gas by the dry distillation of coal was known long before its commercial use was thought of. We have seen somewhere a statement that the Dean of Kildare, the Rev Dr John Clayton, wrote to Robert Boyle in 1690 describing how he filled bladders with an inflammable gas obtained by distilling coal, and Stephen Hales in 1726 published the fact that on distilling 158 grains of Newcastle coals 180 cubic inches of "inflammable air" was obtained. And did not Bishop Watson touch on the same subject? Perhaps some of our readers can inform us.

REMINISCENCES OF DR. CARO*

By Dr. E. F. EHRHARDT

"Psycho-analysis seeks to secure a healthy flow of the emotions by eliminating the impurities which by repression have contaminated the well-spring of our inner life. It is an aspect of the moral purification—the catharsis—to which Aristotle attributes the virtues of tragedy."

This is a quotation which expresses, in more beautiful language than I can dispose of on ordinary week-days, one of the reasons for the choice of my subject for a paper to you to-day. In more Victorian language the same idea would be expressed by saying, "Don't nurse a grievance but have it out."

Of all the great chemists and great lawyers that it has been my good fortune to meet, Dr. Caro is the one who seems to me to correspond most satisfactorily to the definition of a genius, and it is perhaps for this reason that he is becoming something of a fetish. It frequently happens that when certain views are to be put forward an endeavour is made to render them more palatable by connecting them in some way with Dr. Caro. Thus when the education of industrial chemists is under discussion someone will advocate what he calls the "German System" and point to Dr. Caro as a product of that system, which should, therefore, be copied. Or, again, when during the war the importance of the dyestuff industry was acutely troubling the Government and numerous dye consumers in this country, a letter was written to *The Times* giving as the solution of the difficulty, "Find a man like Dr Caro and give him a free hand." Suggestions like this that come from people who have not spent as many minutes with Dr. Caro as I have spent days cause a certain amount of irritation and lead to the desire for the catharsis that I have referred to in my opening quotation. I do not propose to give anything like a complete account of Dr Caro's life and work, and will restrict myself to a few but slightly connected reminiscences.

It is unfortunate for those who hold up Dr. Caro as a product of the "German System" for training industrial chemists that he was not trained as a chemist at all. He did attend a German polytechnicum, but he took the course provided not for chemists but for calico printers. This indeed included something of the elements of chemistry and as a consequence of his innate aptitude for chemistry and of the interest he had always taken in that subject, when Caro left the institution the certificate that he received stated that his knowledge of chemistry considerably exceeded the standard required by the institution for the certificate. He repeatedly told this with pride. Dr. Caro opened business life, therefore, as a calico printer with a knowledge of the elements of chemistry, and the production of the first coal-tar colours synchronised with this period and he learnt the chemistry of the industry as it was found out and himself contributed to this knowledge.

Even when I made his acquaintance in 1889 there were properly qualified chemists who looked upon Dr. Caro in much the same way as registered medical practitioners to-day may regard a successful bone-setter whose meritorious services have been recognised by a knighthood. At that time he already had honorary degrees conferred upon him by the Universities of Munich and of Heidelberg, but he had achieved no degree by examination and passed through no regular University course.

On the other matter—that of finding a man like Dr. Caro and giving him a free hand to recreate and develop the dye industry in this country—in the first place, I would ask, where, if you exclude the writer of the letter and present company, would you find the man of genius like Dr. Caro to whom the free hand is to be given? But apart from this difficulty it is one of the attributes of genius that they are frequently difficult to get on with, and in this respect Dr. Caro was not altogether an exception. He served only one term on the Board of Managing Directors of the Badische Co. When his five years' agreement came to be renewed he was promoted to the Supervisory Board. It was shortly before the end of this period that I went to Ludwigshafen and was engaged as a chemist under Caro. When after six months' provisional engagement the definite agreement was to be signed I asked for a salary of M. 3000 per annum as against the regular M. 2400 and gave as the reason for this £30 extra that for me the engagement meant living abroad, so that something ought to be paid by way of consolation for living in exile. Dr. Brunck, who was dealing with me in the matter, snorted at this idea and said in other words, "If you know a better 'ole, go to it," but he added, "we will give you the extra £30, not for living with us here but you have got to work under Caro, no one can get on with him, and we have noticed in the last six months that you have got on with him; we will give you the extra £30 per annum for that." When one managing director speaks like this of a colleague it is not exactly a recommendation that the latter should be given a free hand for running a factory.

Dr. Caro was a man of approximately the same age as my father; his elder children were older than me and his younger children younger. He was kind enough to take a paternal interest in me, and there was no difficulty in a young man like me getting on with him when his coevals might find it very irksome.

It was, and I suppose still is, a social custom over there for the new recruits on the staff to call on the older men, and these calls were paid between the hours of 11 and 1 on Sunday morning. I promptly paid my duty call on Dr. Caro. Instead of letting me go at the end of the regulation 10 minutes he kept me until he was fetched to dinner and insisted on taking me with him. He kept me the whole afternoon, we went for a walk and returned, he kept me for the evening meal, and for the whole of the evening until past midnight filled the time with practically a monologue on the history of the dye industry and his experiences in connexion with it.

* Paper read before the Manchester Section of the Society of Chemical Industry on February 1, 1924.

He made this most interesting to me and he thoroughly enjoyed talking in this way himself and pressed me to come again, and repeatedly my morning calls ended only at midnight. In this way, in addition to the work I did with him daily at the factory in the laboratory, I got to know him very intimately.

The Fast-Red Case

In May, 1889, I was with Caro for about a fortnight in London in connexion with a law suit with reference to Naphthol Yellow S in which Mr. Ivan Levinstein was an ally of the Badische, and Read, Holliday and Sons, Ltd., were in alliance with the defendants Messrs. Dawson. It was then that I met Mr. Ivan Levinstein and naturally the recently ended litigation between Badische and Levinsteins on the Fast Red patent, which had finally resulted in the alliance that I have referred to was frequently discussed. There are one or two points in connexion with that suit that are germane to my subject and which should be published. Everyone who is familiar with patent case law will remember that one of the defences in the suit—Badische *v.* Levinstein—was that the defendants Levinsteins made use of a secret process, not the process of the patent. The evidence on this defence was heard *in camera* with every safeguard against publication, so that to this day details of this secret process have not been given to the world. It would be useful if the text books on patent law when discussing this case would add a foot note giving the nature of the secret process and the reason why the defence based upon it fell. The patent in suit claimed the production of colouring matters by the action of diazo compounds of naphthylamine or naphthylamine sulpho acid upon the naphthols or the sulpho acids of α- and β-naphthol, that is to say, the claim is directed to making the azo dyes from the naphthylamines and from their sulpho acids, diazotised, and combined with the naphthols and their sulpho acids. It is difficult to see how there can be any secret process differing from the normal process which was patented for effecting this combination, and as a matter of fact the secret process did not refer to the patented step, it related to the manufacture of naphthionic acid. After this sulpho acid of alpha naphthylamine had been made by the secret process the treatment was just as claimed in the specification, so that it is clear why this defence failed. The secret process for making naphthionic acid was a baking process using shallow metal trays for the baking operation and breaking up the paste during the process of baking with the aid of stampers.

I learned this from Mr Ivan Levinstein's own lips in the old Gambrinus in Glasshouse Street. Dr. Caro, Mr. Levinstein and I had been at a long consultation with Professor Dewar at the Royal Institution. When we came out Dr. Caro called out that he would like a glass of German beer, which in those days was more difficult to get in London than in more recent times prior to 1914. During my visits to London University for examination purposes I had frequently passed the Gambrinus in Glasshouse Street—it was not then extended to Regent Street as it is now—and I took Caro and Levinstein into this replica of a Bavarian beer cellar as it then was with its bare wooden tables, deeply carved with initials and devices by the customers who patronised the place. Caro was delighted at the Bohemian atmosphere and here the talk drifted to the Fast Red case and I obtained the information that I have given above. Of the chemists that actually took part in the case and who would know of these details I think Professor Armstrong is the only one living.

The battle of the Fast Red case was, of course, fought again and again and from what I learnt of what passed behind the scenes and from the official reports I think it highly probable that it was putting forward the false point of the secret process and one other small false point that turned the scale and gave the final victory to the Badische.

The Method of Sulphonation

The main attack on the patent was on the ground of insufficiency and centred on the directions given for sulphonation. For this purpose fuming sulphuric acid containing 80 per cent. anhydride was recommended, this was to be applied in the sulphonation of the naphthylamines and of the finished colouring matters. Someone on behalf of Levinsteins made the false point that it was very difficult to sulphonate the naphthylamines with such strong fuming acid and *a fortiori* it would be more impossible to treat a complex body like the azo dye from naphthylamine and naphthol with this powerful acid. The underlying idea was: the more complex the body, the less likely it would be able to withstand the action of a strong fuming sulphuric acid. This is absurd, there is no connexion of that sort and in the case in point the exact opposite was the truth, the complex body, the finished dyestuff could readily be sulphonated with the strong acid whilst the naphthylamines without very special precautions could not be treated with that acid without charring taking place.

When the conflict of evidence on the action in this respect had utterly bewildered the Judge he decided to have an independent expert to repeat the reaction but chose as the crucial experiment the treatment of the dyestuff naphthylamine-azo-naphthol with this acid and not the treatment of the naphthylamines, and the sulphonation of the dyestuff was effected with perfect success by Sir Henry Roscoe, which gave the Badische Fabrik their victory.

I asked Dr. Caro how it came that the direction to sulphonate with this strong acid was included in the specification and the history is of interest. I suppose everyone is aware that on the Continent the strongest concentrated sulphuric acid is sold as "66°" acid being 66° of Baumé scale. It appears that at about the time of the Fast Red invention a firm on the Continent put on the market a fuming sulphuric acid which perhaps roughly speaking was as much stronger than 65° acid as 65° acid is stronger than 50 acid, so they called their acid 80° acid, although the degrees bear no relation to its specific gravity at all. One could imagine a chocolate manu-

facturer advertising his cocoa as 100 per cent. pure and a rival manufacturer who offered a stronger cocoa calling his 200 per cent. pure. The action of this sulphuric acid firm was similar. The strongest ordinary acid was 65-66 acid, they sold a stronger acid as 80° acid, it was this 80° that was used by Caro's assistant—a promoted laboratory boy—for the sulphonations in connexion with this work and he had not the education to distinguish between degree sign and the percentage sign, so in his note book called this acid 80 per cent. acid, putting the percentage sign instead of the degree sign. This was copied into the draft specification and so gave occupation to the leaders at the Patent Bar and all the courts up to the House of Lords in this country. Caro told me that it was his intention to go into the box as a witness and explain this to the Court and to rely on the sense of justice of the Judge not to upset the patent for the sake of a mistake like that, but he was prevented from giving evidence by illness. Another of the witnesses has boasted to me that he won that case by making Caro ill with a surfeit of champagne and so prevented his giving evidence.

Superstitions

Dr Caro was superstitious in many ways or, at any rate, pretended to be. Thus, on the occasion of this Naphthol Yellow law suit he wore a peculiar diamond pin, in the centre of which there was a pear-shaped diamond mounted as a pendant. The swinging of this diamond every time he moved attracted my attention, and when he noticed that I was looking at it, he explained to me that it was a talisman and that he always wore it when he had important business on hand but never on ordinary occasions. For many years afterwards I repeatedly noticed that this talisman pin was put on when it might be regarded as desirable to propitiate the fates. The photograph that is published in the *Berichte* with Caro's biography written by Prof. Bernthsen shows this pin, which he wore when that photograph was taken. Another instance of this trait is afforded by his account of his invention of the reduction of nitro "propriolic" acid, which was the first technical production of artificial indigo. All efforts to find a suitable reducing agent for "propriolic" had failed, then Dr. Caro one night in a dream saw in letters of flame before him the words "xanthate of soda," and tried the next day xanthate of soda. It worked perfectly, and the "propriolic" acid was put upon the market for indigo printing. I suggested to him that the supernatural powers who had favoured him in this way might have given him a hint how to prepare indigo in bulk, for after all the manufacture and sale of the "propriolic" acid was more a matter of prestige than of dividends, but he did not take the criticism of his spooks kindly.

Similarly Dr. Caro liked to emphasise the effect of chance on his inventions. One of the most important was his invention, independently of Perkin, of the commercial process for making alizarine. Graebe and Liebermann had brought to the Badische their process for making alizarine by brominating anthraquinone and fusing the dibrom-derivative with caustic alkalis. The first question that was put to them was whether instead of the highly expensive bromine, sulphuric acid could not be used to prepare a sulpho acid of anthraquinone which could be fused with caustic; they reported that they had tried it, but had failed. Every effort was made to make Graebe and Liebermann's process technically possible but without success, and the experiments were flagging or almost abandoned. For the purpose of the experiments a considerable quantity of anthraquinone—a rare product in those days and not readily obtainable—had been got together. Caro wanted to find some use for this anthraquinone, which had been acquired at considerable expense, and just as he had prepared Rosolic acid from phenol he thought he could prepare something similar from anthraquinone by heating it with sulphuric acid and oxalic acid, and this experiment was set going in a porcelain dish. He let the temperature rise gradually, the oxalic acid began to decompose and passed away as CO_2, and he had given up hope that the experiment would prove a success when he was called away from the laboratory and forgot to remove the Bunsen burner from under the porcelain dish in which the sulphuric acid, anthraquinone and oxalic acid mixture was being boiled. Upon his return to the laboratory the place was full of fumes of sulphuric acid, and the contents of the dish had been evaporated to dryness, and round the edge of the crust, which was partly charred, Caro noticed a pink line. He interpreted this as proving that energetic boiling of the anthraquinone with sulphuric acid had led to some sulphonation, and the subsequent dry distillation had got rid of the sulpho group, giving the oxy groups which, with a trace of alumina derived from the porcelain, gave this pink line, showing the presence of alizarine. He at once experimented again, taking the strongest fuming sulphuric acid available and heating energetically, and succeeded in getting sulpho acids of anthraquinone, which on melting with caustic gave alizarine and its isomers as desired. The provisional specification was at once despatched to England, and had the luck of being registered at the Patent Office one day before Perkin's similar application. That was a momentous day for the German dye industry, Caro's patent was No. 1936 of June 25, 1869, and Perkin's patent No. 1948 of June 26, 1869.

Chance and the "Benzene Ring"

Another instance of a chance visit leading to important effects was the experiment which enabled Caro to put the dyestuff factories in a position to break up the "Benzene Ring," that is to say, the commercial ring of producers and dealers in benzene, who were raising the price to the dyestuff manufacturers. This story has a prologue which played in this country. During Caro's partnership in the firm of Roberts, Dale and Company an inventor came to that company with a process for the manufacture of oxalic acid. He prepared oxalic acid by running coal gas from the ordinary gas supply mains into nitric acid, when after a short time crystals of

oxalic acid appeared in the nitric acid solution. Roberts, Dale and Company were manufacturers of oxalic acid, and had recently put down new plant for the purpose. He brought the invention to them to see if it was of any interest, and Caro undertook the work of testing the process. He tried the experiment running the gas through the nitric acid and obtained oxalic acid. If that had been all it would have only been necessary to make a costing to show that the process had no advantage over the old process of making the oxalic acid from sawdust, but to the dismay of Roberts, Dale and Company not merely was oxalic acid obtained, but a noticeable quantity of nitro-benzene was also produced as a by-product. That put the matter in a different light. If nitro-benzene, which was then very expensive, were obtained in this way it was the oxalic acid that might be the by-product and the new oxalic plant of Roberts, Dale and Company would have at once been worthless. The process was condemned, nothing was said about the production of nitro-benzene, and the matter was left like that. Many years later when the " Benzene Ring," to which I have referred, had come into existence, and was seriously worrying dye manufacturers, Caro remembered this old process, and in his writing-room he started an experiment letting coal gas bubble through a beaker containing nitric acid on his window-sill. He had hardly got the experiment started when Prof. Witt called upon him, and he drew the curtain so that Witt should not see what was going on and attended to the business with Witt, during which the experiment was completely forgotten and the gas went bubbling through that nitric acid all night. When Caro saw the beaker next morning he saw a little oxalic acid but, on the surface of the nitric acid, there was quite a considerable layer of oily liquid which turned out to be almost entirely benzene; a little nitro-benzene had been formed, and this had washed the benzene out of the coal gas. This led to experiments on coal gas with other solvents, and it was soon proved that the coal gas, as delivered in those days, contained a quantity of benzene that had not been suspected at all, and that this could readily be extracted from the gas. The dye factories got into touch with the gas manufacturers behind the backs of the tar distillers, and with the aid of this process obtained from the gas factories a supply of benzene at the crucial moment, which forced the members of the ring to come to terms.

Jacketted Pans

Before concluding, I would like to register one claim that Dr. Caro made which I have never heard discussed or seen published in any way. He claimed to have introduced into the chemical industry the use of jacketted pans; these are nowadays so much a matter of course that it is difficult to realise that someone had at some time invented and introduced them. Dr. Caro told me that it came about in this way. In his early laboratory work he used an ordinary English glue pot as a convenient water bath for making small experiments, and found glue pots so useful for this purpose that he took some to Germany when he went over there and used them there for laboratory work. When larger scale plant was required, larger glue pots were made, and in this way the jacketted pan as we know it to-day arose.

Now the rest of the acts of Dr. Caro and the inventions he made, and the honours and decorations that were bestowed upon him by Princes and by Universities and by Scientific Societies, are they not written in the official biography of Dr. Caro by Prof. Bernthsen in the *Berichte* of the Berlin Chemical Society, Vol. 45?

* * *

In the subsequent discussion Prof. Green said he did not know whether the story was apocryphal, but he remembered being told about the way in which it was sought to convince the judge in the Fast Red case that the method of sulphonating α-naphthylamines, as described in the patent, was not practicable. The judge was invited into a small back room, and a pound of α-naphthylamine was placed in a big pot and 4 or 5 lbs. of 80 per cent. fuming sulphuric acid was poured on to it. There was a frightful commotion at once. In one moment, the room was full of SO_3 fumes, and the Judge and everybody else got away as quick as they could. The Judge declined to see any more experiments. Dr. Caro was certainly one of the greatest men the dyestuff industry produced. He had a wonderful genius for discovery, and a marvellous enthusiasm for chemistry which was a science he loved from the bottom of his heart. In many respects, he was a poet. He did not necessarily write in verses, but anyone who had read the Lecture delivered before the Berlin Chemical Society on the Development of the Dyestuff Industry would realise that it was an absolute epic and one of the most beautiful pieces of writing imaginable. He could not say that he had the pleasure of knowing Dr. Caro well. But he did call upon him occasionally at his flat in Mannheim. One of the reasons Dr. Caro left Manchester was ill health. He went straight to Heidelberg, and lived there for two or three years, practising as a general consultant. Very soon all his time was given up to the Badische Co., and eventually he joined their undertaking. After leaving the Badische Co., he still resided in Mannheim. Dr. Caro's daughter was very intimate with his (the speaker's) wife and they occasionally corresponded. In fact, his wife received a letter from Miss Caro only a few weeks ago in which was enclosed an interesting bit of correspondence which was not entirely without some reference to the present conditions in the dyestuff industry. It was a curious thing how history had repeated itself over and over again. In 1904, just after Dr. Caro's jubilee, Prof. Meldola wrote on February 17: " My Dear Caro, . . . I write now to offer you my sincere congratulations, and to express the hope you may be spared for many long years yet to enjoy your well-earned period of leisure and to pursue your scientific work. *The worst thing that ever happened to the coal-tar colour industry of this country was the loss of Heinrich Caro!* Now we have nearly lost the industry altogether,

and serve us right!—Yours very sincerely, R. Meldola." Caro replied to this letter on March 2, 1904:—

"My Dear Professor Meldola,

Allow me heartily and sincerely to thank you for your very kind congratulations on the past jubilee of my 70th birthday. Your good wishes have not come too late. The bright sunlight of friendship and fellow feeling which threw its radiant beams upon that wonderful and never-to-be-forgotten day, has not yet passed away, and as long as it lasts the days may roll on in their ordinary course, but the 13th of February will still remain in existence. I feel very happy that my dear old friend and colleague, Professor Meldola, has on that memorable day shaken hands with me wishing me good luck on my onward way.

In your kindly worded letter I have noted an expression, which, coming from an authority like yours, has assumed the character of a verdict. You are alluding to my former participation in the rise of the English coal-tar industry, and then you go on to say its truly deplorable decline may be partly traced back to my leaving your country in 1866. Now, my dear Professor, with all due respect I beg to be allowed to differ from you in my views on that question. I think that *many* fatal circumstances had been working together to shift the leadership in the development of the Colour Industry from England into Germany. At about the same time, the great and successful manufacturers, Perkin and Nicholson retired from business; Hofmann, then the real head of the scientific "General Staff," left his glorious laboratory in the Royal Institution and recreated a new era of scientific progress in Germany; his English school was scattered to the winds; Adolf Baeyer commenced his splendid career in Berlin; Kekulé's benzol theory remained, comparatively speaking, disregarded and fruitless in England whilst in Germany the laboratories became too narrow."—(*i.e.*, too small for the students)—"The worst thing was that the English manufacturing chemist, in consequence of his innate self-reliance, trusted rather to his own energy and practical experience than to the skill and knowledge of scientifically thoroughly trained assistants: Wishing to save wages he himself spoiled his own trade, and when he bethought himself of his folly, the reins had already slipped from his hands. If I had remained in England I could not have stopped the fatal change. I see now no reason why the lessons of the past should not be rendered fruitful by the present generation of English chemists, who, as your own noble example shows, are in respect of the high qualities of heart and mind certainly not inferior to their German colleagues.—Ever yours, H. Caro."

Although Dr. Caro was an intense patriot, and had an intense belief in the great potentialities of German science, enterprise, and industry, he yet had a very tender spot in his heart for England. It would have been a terrible thing for him if he had lived to see the war, but fortunately he did not. He always used to speak with the greatest pleasure about the period of his life that he lived in Manchester. He always seemed to look back upon it as one of the happiest parts of his life.

Prof. Knecht said he knew Dr. Caro in 1883. At that time he, the speaker, was making the homologue of resorcin, and from it a fluorescein, and from that an eosin. Victor Meyer, whom he was assisting at the time, strongly urged him to see Caro, and an interview was arranged shortly afterwards in Switzerland. He showed Dr. Caro some fluorescein and eosin dyed on silk. Dr. Caro took a considerable interest in the method and said he would try it in the works. There was considerable difficulty in making the homologues, and the experiment proved a failure. Subsequently, he met Dr. Caro frequently in this country, and could bear out Dr. Ehrhardt's statement that if he took a fancy to anyone he invariably gave them rather long lectures. Personally, he remembered being at Dr. Caro's house in Mannheim on a Sunday, and he gave him the lecture he had delivered to the Berlin Chemical Society in great detail. It took six hours to do it. It was very interesting, but he was very tired when it was finished. Dr. Caro gave as one of the reasons why he was so successful that whenever he made a discovery he went on with it until he had got something out of it of a definite character, and then only did he look in the literature to see if anybody else had done anything of the same kind. He also attributed much of his success to his early training in calico printing, which always stood him in good stead in the works; and what Caro said in this respect was borne out also by Bohn's experience and the experience of various other technologists.

THE ALCOHOL INDUSTRY IN CANADA

The alcohol industry has been revivified, but whether this be due to the repeal of prohibitory legislation in the provinces of Alberta and Manitoba, and the possibilities of a similar result of a referendum in Saskatchewan and Ontario, it is difficult to say. The Canadian Industrial Alcohol Co., of Montreal, has been improving its various plants and bringing them up to a higher degree of efficiency. At its Corbyville, Ont., distillery, among the improvements have been the installation of a plant for the recovery of the carbon dioxide from the fermentation tuns and production of compressed gas, and a new method for the manufacture of high grade ethyl acetate and several other ethyl and amyl compounds. A subsidiary known as the Canadian Industrial Alcohol, of Manitoba, has been incorporated with a capital of $2,000,000. The distillery is now being erected at St. Boniface, Man., and the company is also considering the erection of a plant in British Columbia.

The Commercial Alcohols, Ltd., Montreal, has been incorporated and is proceeding with the erection of a distillery to have a daily production of 1500 gals. alcohol. The raw material will be Cuban molasses which will be transported by tank steamers.

THE OUTLOOK IN CHEMISTRY*

By PROF. SIR WM. J. POPE, K.B.E., F.R.S., D.Sc., LL.D.

One of the many useful functions of an ancient Society such as this is undoubtedly that of taking stock, from time to time, of the actual position which has been so laboriously achieved in one or other of the large divisions of pure or applied science. This, I feel sure, is a function which would appeal particularly to the gentleman whose services to science are to be perpetually recalled to fresh generations of students of science by the Trueman Wood lectures. And so, when the Council of the Royal Society of Arts did me the honour of adding my name to the distinguished list of Trueman Wood lecturers, the opportunity seemed appropriate for directing attention more particularly to one specific branch of science in which developments of fundamental importance have quite recently taken place.

I believe, and I think my belief is well founded, that the historian of the future will mark the last twenty-five years as one of the really memorable stages in scientific progress. This brief period has witnessed such a broadening in the scientific outlook on the physical sciences as was never contemplated towards the end of last century: a broadening of the scientific horizon which has forced previously dissonant sections of the scientific community to regard their individual subjects and their main objectives of research from precisely the same standpoint of knowledge and of purpose.

Some obscurity may attach to this problem and a little explanation is desirable. During the nineteenth century the physicist was largely concerned with the determination of essential physical constants and the establishment of the primary relationship between the various forms in which energy manifests itself; it would be difficult to overestimate or overstate the intellectual beauty of the work of Thomas Young on the undulatory theory of light, of Clerk Maxwell on the properties of gases, or of Kelvin on thermodynamics and the theory of electricity. During roughly the same period the chemist dealt in the main with the material changes brought about in ponderable matter by chemical reaction; Lavoisier's recognition of the elements and his law of the conservation of mass, Dalton's establishment of the atomic theory, Frankland's doctrine of valency and his work on organic synthesis, and the development of organic synthesis by Perkin, Baeyer and Emil Fischer, are among the many expressions of genius directed towards purely chemical ends in this particular epoch. But whilst both Physics and Chemistry developed rapidly during the nineteenth century, they developed on what appeared to be quite divergent lines; they had but little community of method, of purpose or of outlook, and the chemist was fairly sharply distinguished from the physicist in his mode of attacking a problem and his conception of the meaning of natural phenomena. To the chemist, and especially the organic chemist, the internal constitution of the molecule was the main object of enquiry, whilst the physicist, in his dealings with matter and energy, concerned himself chiefly with extra-molecular happenings; this statement is, of course, not entirely true, and it became less true as time passed on, but it is sufficiently accurate as indicative of the diversity of outlook.

During the last twenty-five years this state of affairs has entirely changed; the physicist has developed methods for penetrating into the atoms of which molecules are made up and of elucidating the manner in which the primitive atoms themselves are built up; he has provided simple explanations of many remarkable chapters in chemistry which had been worked out in an almost entirely empirical manner with but little theoretical basis. To-day, Physics and Chemistry are but arbitrary subdivisions of the great subject of Natural Philosophy; each of their students is a specialist cultivating some minute field of the whole domain, but all have the same fundamental conception of the nature of the non-living part of our universe.

It is very interesting to attempt a comparison of the outlook of the chemist of thirty years ago with that of to-day; to make such a comparison involves a brief review of the appearance of the chemical universe then and now, indicating the milestones in the path of progress, and remarking on their significance.

Undoubtedly the atomic theory enunciated by Dalton in 1803 remained for a century the corner stone of the chemical edifice; in essence, the atomic theory postulates that any chemical element is composed of inconceivably minute and similar particles called atoms and that the atom of different elements combine in simple numerical proportions to form the ultimate characteristic units, the molecules, of chemically compound substances. It has always seemed to me that Dalton's atomic theory had, at the date of its enunciation, no sure foundation as a logical interpretation of observed facts, though it is naturally impossible to recover precisely the outlook of the chemist of a century ago; but whether the atomic theory represented a logical interpretation of experimental observations, or whether it expressed an inspiration of a great generalising intellect, it is clear that until a few years ago the atomic theory remained a theory and nothing more. Ostwald, indeed, made an earnest attempt to present modern chemistry without the aid of the atomic theory and, notwithstanding the recognised utility of the theory as a piece of chemical scaffolding, few held the opinion until quite recently that the atomic theory depicted an actual state of affairs or supposed it proved that atoms and molecules actually exist. After Dalton came Avogadro, who in 1811 stated the hypothesis that under similar conditions of temperature and pressure equal volumes of different gases contain the same number of molecules; again, no complete logical proof could be given that what was often erroneously described as Avogadro's Law represented an actual state of affairs; nevertheless, Avogadro's hypothesis still

* The Trueman Wood Lecture, delivered before the Society of Arts, on May 21, 1924.

stands as the mechanism for rendering intelligible our methods for determining molecular weights.

Other great chemical monuments were raised from time to time: Prout's hypothesis stated in 1816 that the atomic weights are integral multiples of that of hydrogen and become whole numbers if the atomic weight of hydrogen is taken as unity, and Mendeleef's periodic relationship between the atomic weights and physical and chemical properties of the elements, dating from 1869, had a profound influence on chemical thought. Prout's Law was temporarily discarded, to be resuscitated a century later in a slightly modified form as perhaps the most striking exemplification of the truth of modern views of the nature of matter and energy: Mendeleef's periodic classification of the elements remained for half a century as a purely empirical justification of a rapidly increasing belief that the elementary atoms are complex structures and that all have a common origin.

With the rapid development of organic chemistry came the enunciation by Frankland of the doctrine of valency, with its immediate clarification of our knowledge of the molecular constitution of organic compounds; the introduction of constitutional formulæ by Kekulé gave a directional lead to the work of the organic chemist, and this mode of expressing the position relationships between the atoms composing a molecule, based upon the doctrine of valency, has furnished the theoretical network upon which the whole of the vast expansion of organic chemistry has been spread. Again, however, the doctrine of valency represented an empirical conception in the sense that it seemed impossible to give it any theoretical interpretation; at the same time, constitutional formulæ, although continually acquiring a more concrete character from stereochemical work based upon Van't Hoff and Le Bel's conception of the asymmetric carbon atom, were commonly regarded as not necessarily of greater significance than expressing a geometrical relationship which was to some extent parallel with the actual state of affairs. Possibly, however, it is not sufficiently grasped by chemists that the introduction of constitutional formulæ, with all their modern consequences such as the recognition of the existence of definite groups or radicles as component parts of the molecule, constituted an entire revolution in chemical thought. I have myself discussed modern organic chemistry with veterans of before Frankland's day and have been struck by their distrust of the idea that individual atoms of the component elements and specific groupings of those atoms exist as such in the complex molecule; the early conception seems clearly to have been that when two dissimilar atoms enter into combination each loses its identity and becomes, as it were, fused into the other. To our predecessors with such an understanding of chemical combination, the attribution of concrete signification to constitutional formulæ must have been peculiarly difficult.

A multitude of other steps in the development of the chemist's conception of his universe, many of them of importance, might be noted, but all are of the same category as the foregoing. The gradually extending chemical outlook of the last century resulted from the exercise of great experimental skill in the collection of observational facts and in the logical generalisation from those facts which yielded the theoretical groundwork of modern chemistry; a wonderfully supple theoretical network was thus built up but it was a network which, in the end, was regarded merely as theory and not as necessarily presenting any real picture of what really exists as causative of the experimental results. This mode of conception has become obsolete during the present century; the atom and the molecule are now known to be realities and much has indeed been disclosed concerning the way in which the elementary atoms themselves are built up. It is interesting to review the manner in which the new outlook has been gained before considering how it affects modern chemistry.

The first step towards a proof of the existence of Daltonian atoms and molecules as concrete entities obviously consists in devising methods for determining some constant relating to their absolute sizes, to the number present in a definite weight of a material or to the mass of an individual atom or molecule; such quantities as these are intimately related and it is convenient, in tracing the development of the subject, to confine attention to but one of them. We may choose for this purpose the Avogadro constant, N, which represents the number of molecules contained in the molecular weight in grams of any species of matter. The mathematical development of the kinetic theory of gases by Clerk Maxwell, Clausius and van der Waals led to a method, based in part on measurements of the viscosity coefficients of gases, by which the Avogadro constant could be calculated; from measurements made on argon, the value $N = 6{\cdot}2 \times 10^{23}$ was deduced. Naturally the calculation of this quantity provides no proof of the existence of atoms or molecules because it is based upon the assumption that they do exist; the point which is of importance, however, is that many quite dissimilar methods for arriving at a value for the Avogadro constant are now available and that all lead to values which are identical within the limits of experimental error.

Thus, the botanist Robert Brown noted in 1827 that very finely divided particles suspended in a liquid appear on microscopic examination to be in a state of perpetual agitation, and some sixty years later it became admitted that this incessant movement is due to the bombardment of the tiny solid particles by the swiftly moving molecules of the liquid medium itself. If this is the case, the solid particles suspended in a liquid should distribute themselves vertically according to the same law as governs the pressure of the atmosphere at various altitudes; very careful series of observations were made by Perrin of the concentration of uniform particles of gamboge at different altitudes in a thin layer of liquid and it was shown that, interpreting these data as representing an equilibrium condition between the dispersive tendency of the bombardment and the sedimenting effect of gravity upon the particles, a method for calculating the Avogadro

constant was obtained. Perrin thus calculated the value $N = 6 \cdot 83 \times 10^{23}$, which, considering the difficulties of the experimental work, may be regarded as identical with the value calculated from the viscosity of argon The remarkable nature of this correspondence will be realised when it is noted that a parallel is being drawn between the weight of a gram-molecule of such a gas as hydrogen, namely, two grams, and that of the gram-molecule equivalent of the relatively enormous gamboge particles, which is of the order of 100,000 tons; also that an atmosphere of hydrogen round the earth would have its density diminished to one-half by the action of gravity at an altitude of about 80 kilometres, whilst a similar diminution to one-half density occurs at a height of 0·02 to 0·03 mm. in the suspension of gamboge.

Again, the late Lord Rayleigh pointed out that the diffusion of light by a gas is due to the gaseous molecules acting as diffracting particles; by an argument which need not now be discussed he traced the blue colour of the sky to this effect and gave a method for calculating the Avogadro constant. This method, applied with modern refinements, has yielded the value $N = 6 \cdot 54 \times 10^{23}$, again sensibly identical with those furnished by the previously entirely distinct methods.

By far the widest expansion in modern knowledge of the constitution of matter, and indeed also of energy, is that which has resulted from the study of radioactivity Apart from the pioneer work on radiant matter by Crookes, the discovery of radioactivity in 1896 by Becquerel and its association shortly afterwards with radium by Madame Curie mark the opening of a fresh chapter in the development of science; so striking has been the broadening of the chemical outlook under the influence of the rapid advance in the study of radioactivity that it may be useful to note a few points of special importance. The most fundamental of these is perhaps the identification by Sir J. J. Thomson of the β-particle as the particle or unit of negative electricity and the demonstration that the α-particle, thrown out during the first stage of the atomic degradation of the radium atom, is the atom of helium carrying one unit charge of positive electricity. Following this as clearing up our ideas on fundamental chemical theory is possibly Rutherford's conception of the structure of the chemical atom; in this it is conceived that the atom consists of a nucleus, minute in comparison with the total volume occupied by the atom, which contains all the particles of positive electricity and, in the case of all the elements but hydrogen, a definite number of particles of negative electricity; the nucleus carries a positive charge equal to the difference between the number of positive particles and the smaller number of negative electrons composing the nucleus. The positively charged nucleus is in electrical equilibrium with the much larger external atomic domain by reason of the presence in the latter of negative particles or electrons equal in number to the nuclear charge. Since the property of mass is chiefly associated with the positive particle of electricity, the electron having a mass only about 1/1800 as great, the atomic weight of an element becomes very nearly the number of positive particles contained in the nucleus; the atomic weights should thus be practically whole numbers, multiples of the unit atomic weight of the lightest element, hydrogen, in accordance with Prout's hypothesis of 1816. Further, one of the most important characteristics of an element should be the positive charge on the atomic nucleus, or the number of electrons in the external atomic domain; this is the atomic number which was first defined by Moseley, who showed the simple relation which exists between this constant and the spectrum of the light evolved by an element when bombarded by β-particles. As connecting this strange new development of science with earlier knowledge it may be noted that the most accurate method for determining the Avogadro constant depends upon the measurement of the charge carried by the electron or β-particle; Millikan thus determined the value for N as $6 \cdot 062 \times 10^{23}$, a number approximately identical with those previously quoted.

It would be impossible in the limited time now available to submit any adequate picture of the far-reaching deductions from recent work on radioactivity; one or two points may, however, be emphasised. The Moseley atomic number shows that 92 elements should exist and 87 of these are now known, five being left to be discovered; it indicates that the atomic weights of all the elements should be whole numbers. Rutherford showed that the atomic nucleus, which gives the atomic weight as the number of units of positive electricity included within it, is composed of ponderable positive particles and practically non-ponderable negative particles of electricity, the difference being the atomic number of Moseley; it appears, however, that the atomic nucleus of any particular element can preserve its identity, from the purely chemical point of view, if containing one or more positive and the same number of negative units of electricity less

The positive charge, the Moseley atomic number, would be thus left unaltered and consequently the identity of the element for purposes of chemical change should remain unchanged. In accordance with this Aston has proved in a large number of cases that the chemical elements are mixtures of atoms of different nuclear composition, although identical as regards the number of negative electrons which compose the outer or chemically active atomic domain. Elements which differ to the extent just indicated in nuclear composition, but which are identical in the number of electrons present in the external domain, have been termed isotopes; it is now known that the atomic weights of each variety of any element appear as whole numbers when referred to a particular unit. For a reason which is not yet elucidated, but which is certainly of significance in connexion with our knowledge of the relation between matter and energy, the unit value for the atomic weight of hydrogen has to be selected as 1·008; this unit chosen, the atomic weights of the isotopes of all the elements appear as whole numbers. The empirical deduction of Prout of a century earlier has thus been completely justified. Again, the purely empirical deduction by

Mendeleef of the so-called periodic classification of the elements, which has exercised enormous influence on the development of inorganic chemistry, has found complete theoretical justification in the arrangement of the elements in sets of eight in accordance with the system of atomic numbers introduced by Moseley. The deductions drawn by Lavoisier about 1775 which indicated the existence of chemical elements and stated the law of conservation of matter both find theoretical justification in modern conclusions; each chemical element is characterised by the Moseley atomic number and the law of conservation of matter stands subject to the slight adjustment involved in the attribution of an atomic weight of 1·008 to hydrogen. Lastly, the atomic theory of Dalton has passed from the stage of being merely a useful hypothesis to that of stating an actual condition of affairs; it is safe to assert that never again in the history of science will the existence of atoms of the elements be seriously challenged.

So far we are on undebatable ground, but much more still disputed territory is in sight which will undoubtedly be secured in the very near future. The nature of chemical combination has been long in dispute: the Frankland doctrine of valency has been very fertile as leading to a classification of types of reaction and to a very perfect system of indexing the composition and constitution of chemical compounds. It seems likely that the Rutherford conception of atomic structure, interpreted quantitatively by Bohr and his co-workers, and adapted to chemical mechanisms by men of the Langmuir and Millikan school, will ultimately provide a satisfactory solution of many of the baffling problems now presented by the question of atomic valency.

Yet another remarkable chapter has been recently opened in connexion with the confirmation by contemporary physicists of the singular accuracy of the manner in which chemists long before had interpreted the observed facts relating to molecular constitution. Frankland's doctrine of valency enabled Kekulé about 1858 to develop the theory of the molecular constitution of chemical compounds, and later generations of chemists have brought to a great state of perfection the methods for ascertaining the manner in which the component atoms of an organic molecule are joined together. The precision of the synthetic methods of organic chemistry and the striking facts of stereochemistry made it certain that the so-called structural formulæ run closely parallel to the actual arrangement of atoms in the chemical molecule; at the same time, no independent or more direct confirmation of the substantial correctness of constitutional formulæ was until quite recently forthcoming.

The purely geometrical investigations of Bravais, extended and completed by Sohncke, Schönflies and Barlow, have long since shown that all properties of crystals are consonant with the supposition that crystal structures consist of a regular repetition in space of the molecular units, and consequently also of the atoms which compose the molecule; any particular plane section of a crystal is thus to be regarded as having a definite reticulated pattern formed by the geometrically regular repetition of component atoms in the plane. It has also been long known that light is diffracted in accordance with well-understood laws from gratings ruled with a large number, say 100,000 to the inch, of fine lines. The reticulated pattern of a crystal surface is, of course, far more minute than corresponds to the dimensions just stated and X-rays are of wavelengths of the order of 1/10,000 of those of visible light. It thus occurred to Laue in 1912 that X-rays should be diffracted from a reticulated crystal surface in the same way that visible light is diffracted by a grating; he showed this to be the case and shortly afterwards Bragg founded upon this observation a method for determining the atomic spacings in a crystal by observation of the manner in which X-rays are diffracted from the crystal. Debye and Scherrer showed a little later that massive crystals are unnecessary for the application of the Bragg method, but that finely powdered crystalline material can also be used, and, in fact, the study of X-ray diffraction from particles of colloidal gold in aqueous suspension has proved that the colloidal particles of this element are crystalline.

The Bragg method has been intensively applied during the last few years and has demonstrated that the constitutional formulæ deduced in an entirely different fashion by the chemist are substantially correct representations of the actual manner in which the atoms are arranged in the chemical molecule.

This necessarily very abbreviated summary of the most important directions of recent progress in physics in so far as they influence chemistry will suffice to prove a quite simple thesis. Whilst the chemist at the end of last century had laid certain theoretical foundations to his science, more particularly those connected with the atomic theory, the doctrine of valency, the Mendeleef classification of the elements, and the vast network of organic chemistry which culminates in the determination of molecular constitution, all these achievements remained as theories or even in part as mere hypotheses until the sudden development of physics during the last twenty years or so transformed them into actual statements of fact. The history of science has never before had to record so dramatic and far-reaching a broadening of the horizon as that which has so recently unified chemistry and physics.

It is doubtful whether the importance of the unifying process which has been carried out so rapidly has been sufficiently realised by the majority of those interested in physico-chemical science, and attention may be directed to one aspect of the question which appears to be relevant.

Whilst the present generation of students is acquiring an outlook very different from that prevalent a few decades ago, our general organisation of teaching methods remains unchanged. The student commences his training in natural philosophy by attending separate courses in inorganic and organic chemistry and in general physics, including heat, electricity and magnetism. But the reason for this early differentiation has now entirely vanished, if indeed it ever really existed; all these

subjects have the same basis, namely, the electronic constitution of matter and energy, and it would seem more rational for the student of natural philosophy to commence his training by a general course for the purpose of elucidating the manner in which all these specialised sections of the one large subject fit into the one great scheme. Students have frequently asked me how to reconcile the tenacity with which a complex molecule of an organic compound retains the perfectly definite arrangement of its component atoms with the view that an atom itself is but a minute nucleus surrounded by a large planetary system of particles of negative electricity in rapid gyration: there is indeed a striking contrast between the rigidity of molecular structure evinced by organic compounds and the apparently flimsy nature of the rotating sub-atomic units from which the whole wonderful edifice is built up. Our teaching methods require considerable adjustment to make them fit the exigencies of the modern scientific outlook.

Probably I have said sufficient to make it clear that the outlook in chemistry is far broader than it was twenty-five years ago; we understand now the meaning of much that had been painfully deduced by generations of careful observers of experimental facts. We may now proceed to enquire what we see in front of us as the result of the wider outlook.

All enquiring minds in science are accustomed to peer into the future in an attempt to discern the directions in which progress is possible; hundreds of imaginative writers have tried to foretell the effects upon human life which will accrue from coming advances in science. In this connexion I desire to submit one ruling principle, a principle which is admirably exemplified by the directions of progress during the present century and which appears to be as yet but ill recognised. The principle is that all scientific prophecy which goes outside what will obviously and logically result from the normal and unsensational development of the existing scientific position is necessarily false. No one in 1900 ever conceived anything so sublime and yet so fantastic as the achievements of the past quarter of a century.

Fears are often expressed that humanity is being impoverished, and that posterity will be embarrassed by the rapidity with which our coal and petroleum resources are being consumed; but it is reasonable to presume that long before these potential supplies of energy have disappeared, their applications will have become obsolete. Whilst every motive exists for employing our present sources of energy with the maximum efficiency, we may safely leave posterity to look after itself with the aid of the scientific heritage with which it will be endowed. The desire to leave coal and petroleum for our successors to consume shows benevolence, but appears no more rational than the action of our ancestors in planting England with oaks after the Napoleonic wars, so that we might not lack material for the building of battleships.

But whilst we cannot see far into the scientific future, we can safely foretell certain immediate consequences of the position which chemical and physical science has so lately attained: we are confident that the period, 1925-1950, will be as prolific of discoveries previously unimagined as was the period 1900-1924, and it is futile even to speculate concerning the entirely novel conceptions and discoveries which the next quarter of a century will bring in natural philosophy.

It may be taken for granted that the Bragg method for determining crystal structure, which is still in its infancy and not so far capable of dealing directly with the lighter elements, will provide a means for locating accurately all the atoms present in any molecular complex, either inorganic or organic. This must lead to a great development in our knowledge of chemical structure, and should enable the relations between chemical constitution and physical properties, many of which have merely been studied empirically up to the present, to be discerned and stated with precision. Thus, it may be expected that the exact relation between the molecular configuration of an optically active substance, and its molecular rotatory power will be ascertained.

Our present knowledge of atomic constitution, with its inevitable developments and its applications to the elucidation of valency, and the elaboration of purely physical methods for determining molecular constitution, may be expected to throw light on an almost infinite number of points of detail in organic chemistry which are still obscure. We may expect to learn the cause of the great stability of the benzene ring, the basic principle underlying the tautomerism exhibited by ethyl acetoacetate and its analogues, the origin of colour in the quinones, and why copper of atomic number 29 refuses to form organo-metallic compounds whilst its followers in the series of the elements, namely, zinc, gallium, germanium, arsenic, selenium and bromine, of atomic numbers 30 to 35, all combine with methyl radicles. A quantitative explanation of the energy changes which accompany chemical reactions is to be anticipated. An exposure of the mechanism attending chemical changes in general and of catalytic reactions in particular should be forthcoming; the importance of this latter in connexion with the chemical operations performed by living matter, as bearing upon the utilisation of energy at low potentials for synthetic purposes, can hardly be exaggerated.

A myriad of other obscure questions, which the chemist has already carried nearly as far as his classical experimental methods will permit, but which are obviously open to further elucidation in the light of modern methods, will suggest themselves to the intelligent student of chemistry. A danger, indeed, exists that we may encroach on the domain of the imaginative writer of fiction by speculating on the new chemistry which is foreshadowed by Rutherford's transmutation of the elements by the α-particle bombardment of the atomic nuclei, and on the complications which will ensue when the several isotopes of many of the elements are available in quantity; although it is often stated that the isotopic varieties of an element will never be isolated in such quantities

is are necessary for chemical work, yet it is difficult to believe that this state of affairs will long persist. It may be taken for granted that in due course the isotopic chlorines of atomic weights, 35 and 37, will be available in quantity.

Up to the present, I have only discussed the change in the chemical outlook which has resulted from the superb achievements of modern physics, but another and very dissimilar factor has been simultaneously operative. Although the theoretical basis of modern chemistry is of a comparatively simple character, the mass of exact and detailed experimental material laboriously collected and recorded during the last century has made every chemist a specialist; each has ultimately been forced to settle down as a cultivator of one minute patch of the vast chemical domain. A tendency towards individualism has thus been fostered. If we look around, however, we see that a tendency in a contrary direction has become operative, namely, towards combined action for the purpose of producing a definite mass effect. The coal-tar colour industry furnishes an illuminating example of this effect; for many years past a large community of most competent chemical investigators has devoted its attention to the exploitation of the subject of dye-stuffs in conjunction with similar bodies of industrial and commercial experts. It cannot be denied that this co-operative effort has produced remarkable results; not only has it, in a comparatively brief span of years, succeeded in dominating one of the oldest and most conservative industries in the world, but it has extended its influence in many other directions. The coal-tar colour industry has, in fact, made itself essential in the production of materials necessary to many other industries, such as those of pharmacy and photography; whilst avowedly commercial in its aims, it has contributed much to the purely scientific development of organic chemistry.

Something very similar has taken place in the electrical industries. Certain of the great research laboratories which form part of a number of electrical firms have made most valuable contributions to the science of pure physics; they can afford a huge expenditure of money for scientific equipment, and can attract the assistance of real leaders in contemporary science.

In chemistry itself the advantages of collective effort towards the extension of industrial efficiency is not confined to the coal-tar colour industry; it is seen in the gas industry and in the novel institution, fostered by experience gained during the war, of research establishments each devoted to the development of some specific large branch of manufacturing industry. But if chemical science is to carry its full responsibility in connexion with the amelioration of the conditions of life, far more must be done to ensure sufficient team work in developing the applications of chemistry to human interests.

A few examples will illustrate this. The spirochaete of syphilis is susceptible to treatment by certain organic arsenic compounds; knowing this, Ehrlich conceived the idea of studying the therapeutic action of a long series of such compounds for the purpose of selecting the most suitable for the treatment of this disease. He ultimately decided that one particular substance, the so-called 606, was the most satisfactory curative agent from amongst the many which passed through his hands. Since Ehrlich's day other organic arsenic compounds have been introduced for the treatment of this particular disease, but all present certain disadvantages and possess certain limitations in efficiency. No thinking person can doubt that if 10,000 compounds, all variously toxic to the spirachaete, had been studied, one immeasurably superior to all the others as a curative agent would have been found; this could have been easily done by team work, and such a discovery would have repaid thousands of fold the original outlay on experimental work. A similar tale has to be told concerning sleeping sickness: Bayer 205 seems to be useful, but something much better would certainly have resulted from the examination of some scores of thousands of chemical substances. No such success can be claimed in connexion with the foot-and-mouth disease, which has cost the country many millions of pounds during the last year, because team action has not been enlisted, and consequently absolutely nothing is available for the treatment of this particular malady. A pressing need exists in this country for an organisation with the duty of drawing up schemes for the preparation of long series of related compounds of possible therapeutic value, making the substances and subjecting them to pharmacological investigation

Let us take another instance. The common and the noble metals have been for centuries the materials of staple industries in many parts of the world; no one metal finds industrial applications in a state of purity, but all are used as alloys with other metals. This being the case, and since none of the alloys in general use approaches perfection, it would have been anticipated that by this time we should have been in possession of an elaborate scheme of experimental data which would provide exact information concerning the properties of every possible admixture of one particular metal with one or several other elements: the scheme would, of course, be a very complicated one, but not nearly so complicated nor as difficult and costly to work out as our present system of organic chemistry.

In spite of much pioneer work by Sorby, Heycock and Neville and many others, no such scheme has been evolved; the National Physical Laboratory is now just initiating an experimental investigation for the purpose of studying the alloys of pure iron and chromium, and this, if successful, will be the first occasion on which the systematic study of alloys of pure iron with another pure metal has been undertaken.

Much more might be said on the need for a broader outlook on the applications of chemistry to other sciences, and to the arts, and on the necessity for the detailed working-out of large and comprehensive plans, involving much experimental work of a rather routine or repetitive nature, so as to provide the vast amount of precise data always essential to any

application of chemistry to technical ends. Many cases in which valuable results would be thus achieved will occur to anyone familiar with chemical science and acquainted with its bearings upon other branches of knowledge.

FORTHCOMING EVENTS

June 2. SOCIETY OF CHEMICAL INDUSTRY, *London Section.* There will be no meeting of the Section on this date.

June 3. ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, 35, Russell Square, W.C. 1, at 7 p.m. "The Analysis of Motion by Kinematography."

June 3 to 6. EMPIRE MINING AND METALLURGICAL CONGRESS, to be held at the British Empire Exhibition. Among other items, papers will be read on the following subjects:—Mining, Petroleum, Metallurgy of Iron and Steel, as well as Non-Ferrous Metallurgy.

June 4. INSTITUTE OF METALS, Annual General Meeting, at the Institution of Mechanical Engineers, Storey's Gate, S.W. 1, at 8 p.m. "Atoms and Isotopes," by Dr. F. W. Aston, F.R.S.

June 4. BRITISH EMPIRE EXHIBITION, WEMBLEY. Conferences on "Heredity as the Basis of National and Industrial Efficiency." Also June 11, 18, 25.

June 5. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1., at 8 p.m. Ordinary Scientific Meeting. (1) "The Absorption Spectra of Camphor and of Camphorquinone," by T. M. Lowry and H. S. French. (2) "Studies in Dynamic Isomerism. Part. XVI. Mutarotation of Beryllium Benzoylcamphor. Formation of an Addition-compound with Chloroform. The Optical Activity of Beryllium," by H. Burgess and T. M. Lowry.

June 6. BRITISH EMPIRE EXHIBITION. Conferences of Engineering Societies to be held in Conference Hall No. 1 at Wembley, at 10.30 a.m. Short Papers on various Engineering Subjects will be read and discussed. Further information as to tickets may be obtained from The Secretary, Society of Engineers, 17, Victoria Street, Westminster, S.W. 1.

June 6. ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 9 p.m. "The Glow of Phosphorus," by Lord Rayleigh.

June 11 to 13. SOCIETY OF DYERS AND COLOURISTS. Annual dinner on June 11 at the Hotel Victoria, Northumberland Avenue, London, S.W. 1. Conference on June 11 and 12 at the British Empire Exhibition, Wembley; on June 11 (3 p.m.) J. R. Hannay will give "An Historical Survey of Dyeing and Calico Printing," and on June 12 (11 a.m.) Prof. A. G. Green, F.R.S., will speak on "Modern Methods of Dyeing." River outing (cost 15s. per person) to Windsor on June 13. Application for tickets should be made to the Society of Dyers and Colourists, 30, Pearl Assurance Buildings, Bradford.

June 12. CHEMICAL SOCIETY. Meeting to be held in the Theatre of the Royal Institution, 21, Albemarle Street, W. 1, at 5.30 p.m., when the Faraday Lecture, entitled "Atomism in Modern Physics," will be delivered by Prof. R. A. Millikan.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

A detailed programme has been sent to every member of the Society.

A ballot list for the election of Members of Council has also been despatched to each member entitled to vote.

J. P. LONGSTAFF,
General Secretary

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

A Member of the Society may purchase a set of Vols. II to VIII inclusive at the reduced price of £2 2s. 6d., and a Non-Member can procure a set at the reduced price of £3 15s., post free in each case.

DEATH

Bailey, Harold J. (elected 1903), of Ingleside, Heath Park Avenue, Cardiff, Alkali Inspector. On April 16, 1924.

MONTREAL SECTION

The annual meeting was held on April 14, preceded by the usual dinner, Mr. F. W. Horner being in the chair. After dinner entertainment was given by "our trio," Messrs. Hovey, Toole and Grigg, followed by a very humorous address by Prof. LeCointe on the Radio and the "Radio Bug." The reports of the Treasurer and of the Chairmen of the various Committees were adopted.

Dr. Wall, of London, England, was called upon by the chairman to address the meeting. During his remarks Dr. Wall told the members of the experience of the London Section relative to attendance, and suggested that more frequent meetings might bring fuller attendance of the members; this was the experience of the London Section.

As no other names were suggested for the offices of Chairman and Secretary-treasurer, Mr. J. B. Bell was declared Chairman, and Mr. C. C. McFee Secretary-treasurer for the year 1924-25. The following were elected members of the Executive Committee: Dr. A. R. M. MacLean, Prof. P. LeCointe, and Messrs. J. R. Donald, F. Cornell, C. G. Kertland, and W. B. Woodland.

Mr. W. H. Barnes then gave a summary of his bursary prize essay on "The Acid Plant—Its Function and Operation in the Sulphite Mill," illustrating his remarks with a number of lantern slides and exhibits of sulphite liquors, and the products obtained by their aid.

OTTAWA SECTION

A meeting was held in the University Club on May 8, 1924. Dr. Macintyre in the chair. The Secretary's report for the 1923-24 session showed the average attendance at the six meetings held to be 32. Prior to three of the meetings dinner was served, an average of 13 members being present. The opportunity thus afforded for closer personal contact appeared to be much enjoyed by those attending. The register contains the names of 18 members and 28 associates being an increase of 2 members over last year. The expenditure for the year was $110·06, leaving a balance on hand of $102·71.

The report was carried and the following officers were elected for the forthcoming session :—Chairman, Dr. A. E. Macintyre ; Secretary, A. E. MacRae ; Committee, Dr. L. F. Goodwin, P. V. Rosewarne, J. E. Goodie, F. C. Collier and F. A. Herman, in addition to Mr. Hambly, past chairman.

The programme for the meeting of Canadian Chemists at Kingston on May 27-29 inclusive, was read by the chairman who urged that as many of the members as possible should be present.

Mr. G. D. Mallory, of the British American Nickel Co., then gave a very interesting address on "The Electrolytic Production of Nickel," first outlining the various uses of nickel and describing the processes used by the International Nickel and the Mond Nickel Companies. He then clearly and fully described the process used at the smelter and at the refinery of the British American Nickel Co.

After an interesting discussion the thanks of the meeting was expressed to the speaker and light refreshments served.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

At the close of the six years during which Monsieur Paul Kestner has presided over the destinies of the Société de Chimie Industrielle, that body has conferred upon him the title of "President Fondateur" to show appreciation of his eminent services. The Bureau and Council of the Société, however, wishing to offer still more complete testimony to the first President entertained Monsieur and Madame Kestner to dinner at the Cercle Interallié. Professor C. Matignon outlined the part played by President Kestner and his influence on the amicable relations with foreign societies, particularly the Society of Chemical Industry. Monsieur R. Duchemin presented to Monsieur Kestner a work of art in the name of the Council, and in well-chosen words, outlined the work he had done. In the name of the National Federation of Chemical Societies in France Prof. Béhal added further testimony, and insisted on the need for the Maison de la Chimie, an idea due to Monsieur Kestner. In reply Monsieur Kestner modestly attributed all the merit to his collaborators, and showed how much work still remained to be done. The new president of the Société de Chimie Industrielle, Monsieur Dior, then paid a warm tribute to his predecessor. The whole evening was remarkable for the spontaneity of the expressions of appreciation and esteem offered to Monsieur Kestner.

The Organic Industries Group met on May 13, to hear a description by Monsieur E. Fourneau of the synthesis of "309" and the changes brought about in the therapeutic action of its derivatives by chemical modifications. The speaker described how he was lead by the study of "Beyer 205" to develop his "309" of which the chemotherapeutic index and properties were comparable with those of the German product. By means of a kinematograph film the synthesis of "309" was explained, and it was shown that by displacing certain groups in the molecule or replacing them by other groups, the therapeutic action could be greatly modified.

Monsieur C. H. Cofignier discussed the thickening of paint, and suggested that for paint containing resin and lead pigments, the thickening could not be sufficiently explained by the formation of insoluble lead resinates. He suggested that the action would first consist in the formation of a grain swelling by adsorption then resolving into finer granules, thus leading to further swelling and to thickening owing to the influence of abietic acid, the presence of a small quantity of which could cause thickening. Completely etherified resins did not give rise to this phenomena. In copal varnish mixed with zinc white or litharge, thickening was caused in a similar way by the free acids of the copals. If gum kauri was etherified with glycerin a neutral resin was obtained which would yield a varnish free from thickening. The free acids were also an important factor. Despite adverse criticisms the speaker still held that the simple formation of lead resinate was insufficient to explain the thickening.

THE DYESTUFFS INDUSTRY IN FRANCE

This industry has continued to develop, the total production having risen from 7056 metric tons in 1920 to 5869 t. in 1921, 8067 t. in 1922, and 10,000 t. in 1923, compared with imports of 5888 t. in 1920, 1148 t. in 1921, 1797 t. in 1922, and 1371 t. in 1923. It thus appears that imports, which represented over 83 per cent. of the production in 1920, corresponded in 1923 to no more than 12 per cent. of the production. The Swiss factory at St. Fols produces roughly 2500 t. annually, an amount not included in the statistics of production. In 1923 France actually imported only 9 per cent. of its effective consumption. On examining the production of dyestuffs it is seen that azo dyes represent 40 per cent. of the total output, with 5124 t. produced, against 444 t. imported. Indigo and its derivatives constitute 24 per cent. of the total, 2132 t. being produced in 1923 and 4 t. imported, whilst sulphur dyes (16 per cent. of the total) represent the production in 1923 of 2279 t., against an import of 58 t. Similar progress has been made in the alizarin, oxyquinone, indophenol, oxazine and thyazine colours. Much progress, however, remains to be made in the commercial production of the vat dyes, which are still imported to a large extent from abroad.

CORRESPONDENCE

THE SCIENCE OF BAKING

Sir,—I trust you will allow me space in your journal for a few remarks anent the recent contribution of the Rev B. V White The reference to one Captain Wimperis, formerly a baker in Boulogne, set me wondering and enquiring Briefly, the result of my enquiries has been to bring to light one Wimperis, who acknowledges to being a dauber, and another who is a word manipulator by profession, but no one of that name, though the Directory mentions several, will admit to having been a dough-thumper Seeing therefore that there was some doubt in the Rev. White's mind whether the Captain's name *was* Wimperis, I have ventured to think that I might be the gentleman to whom he wished to allude. In any case, I am anxious that you should tolerate this incursion on your space to enable me to congratulate the Rev White on his careful and accurate observations of the chemical actions involved in the art and science of bread-making. I shall be grateful to anyone who can put me into communication with this student, nay professor, of what he himself terms "natural knowledge" To come to the case for the scientific study of the processes of bread-making, I have frequently met with the objection that such investigation would result finally in a chemical concoction that would be passed off as bread upon a less suspecting public than that which consumes chemist-controlled beer. So far as beer is concerned I have little knowledge, but I have noticed, as the Rev. White would say, that experts on beer and milk invariably choose the former beverage and do not seem to fear the danger of poisoning. There is, however, no necessity for a chemical-laden loaf to be produced from scientific management of the bakery, which is all that need arise from the results of the investigation.

Though bread-making is one of the most ancient of industries, it has but very recently become one capable of being carried out on the factory scale, and is even now without a scientific foundation Mass production, especially of such an article as bread, demanding close attention to temperature and fermentation conditions and time factors as well as a recognised standard of public taste, necessitates first an intimate knowledge of "what happens," and secondly, a sound knowledge of the various component parts, all of which in the case of bread are necessarily variable in composition

Nor is analytical knowledge by itself sufficient for the manager if regular good bread of standard excellence is to be produced on the factory scale. It would appear that the physical state of the ingredients and doughs in each process of manufacture (and there are many) is of far more importance. Hence it is that a plea is here made for a study of bread-making from the colloid point of view I have had to sit by and watch several Colleges and Industrial Laboratories in the United States and Germany making considerable headway in this study without being able to interest more than half a dozen persons on the subject on this side. Manchester has certainly made a start, and there is one student at the Borough Polytechnic London, who is looking into the matter. And there as far as I know, the study ends. The engineering side of a continuous and automatic plant for the manufacture of bread is even more important than the scientific study of doughs, and it is interesting to note that America, where such plants are common buys 90 per cent., if not all, of its continuous and automatic bread bakeries from a British engineering firm that has specialised in this form of machinery The only completely continuous and automatic bread bakery that I know in this country can be seen at Wembley Exhibition, whilst there must be hundreds in the United States of America.

The baking of bread is not one iota less worthy of scientific study than the manufacture of dyes—there is more in bread than meets the eye.

With apologies for taking so much of your valuable space, I remain, yours, etc.,

R. WHYMPER

THE BRITISH ASSOCIATION OF CHEMISTS

Sir,—In your issue of the 9th inst. is an account of a deputation from the Federal Council to the Board of Trade, in which Sir William Pope is reported as saying that "the Federal Council consisted of representatives of the Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, and all the other organisations connected with English chemistry."

My Council desires to point out that the British Association of Chemists, though having no part at present in the Federal Council, represents an important section of the chemists of the country, more particularly technical chemists interested in the manufacture and use of dyestuffs, and took the earliest possible opportunity of placing its views on the proposed Dyestuffs Agreement before the President of the Board of Trade. A report of the Deputation is to be found in your issue of March 7. and a comparison of the two reports shows a considerable similarity between the views of the two deputations.—I am, Sir, etc.,

I. BOODSON,
General Secretary, British
Association of Chemists

Bedford House,
108, Baker Street, W. 1
May 20, 1924

THE ENGLISH LANGUAGE

Sir,—In reference to recent correspondence in the *Journal* on the above subject, Mr. T. A. Rickard, author of "Technical Writing," was, to the best of my knowledge, born of English parents and received his technical education at the Royal School of Mines London, He has, I believe, only recently become an American citizen.

I do not wish to take up your space, but I think you may be glad of the information.—I am, Sir, etc.,

HUGH F. K. PICARD

44, London Wall. E.C. 2
May 23, 1924

THE ENGLISH LANGUAGE

Sir,—May a humble, pedantic but otherwise harmless, reader of *Chemistry and Industry* offer a little criticism of your editorial and Mr. Allen's letter? First, you would have us believe that you do not know whether it is difficult to write well, because you have never attempted it. Are we then to assume that it is possible to achieve what one has never attempted, or that the rapture of—I forget what character of Molière's, who had written prose all his life without knowing it—is still in store for you?

Mr. Allen is a brother and his letter warmed one's heart. But if there is any splitting of hairs to be done, let me, too, be among the splitters. Consider this quotation from his soul's outpouring:—

"The use of etc., although common and accepted as 'good English,' . . ."

To a purist this sentence is meaningless. What Mr. Allen wished us to read may have been:—

"The use of 'etc.,' although common . . ."

but without the inverted commas his criticism lacks precision. It is also inaccurate. A corrupt Latin abbreviation may be allowable in writing English, but, not itself being English, cannot be accepted as 'good English."—I am, Sir,

[here follows the customary method of concluding letters to the Press, usually abbreviated in a manner hateful to the Precise]

London, S.W. 1 PEDANT

May 26, 1924

THE GERMAN STANDPOINT

Sir,—The various communications in Nos. 16, 17, 18 of your esteemed *Journal* which are concerned with the re-establishment of peace compel me to write you once again.

Prof. Noyes' letter forms a welcome starting-point. One can recognise in it with satisfaction the honest intention to judge the matter from a non-party point of view, and must agree that he succeeds to a certain extent. True, he has not remained immune from the poisonous activity of the anti-German Press, which remains silent over essential facts or turns them into the contrary. In this manner, the foundation on which he builds (*i.e.*, the question of responsibility for starting the war) is shifted to a place to which it does not belong. Prof. Noyes is apparently of opinion that the World War started with the German invasion of Belgium. Such is not the case. The War started with the devastation of East Prussia by the Russians, and the German nation took to arms and anticipated its western enemies only when it saw it would have to make an effort to stave off the fate to which it was destined by St. Petersburg and Paris. Long before the murders at Serajevo Russian troops had stood in close formation on the German frontier; they were prevented only with difficulty from committing too early an invasion of Germany (small detachments had already committed acts of war as early as June) because the army had been worked up to a fanatical hatred of Germany by the agitation connected with the visit of the French President to Kronstadt. Whether Germany sided with Austria in her quarrel with Serbia or remained neutral was immaterial as regards the attitude of Russia and France; the attack on Germany had been decided on, as shown by telegrams between Iswolski and Clemenceau, and was going to be carried out in any case. The march of the Germans into Belgium cannot therefore be put on the same basis as the Russian invasion of East Prussia; the former was a necessary act of war which finds its justification in Belgium's taking part in the Franco-Russian plot, the latter was a deliberate breaking of the peace for which Germany had given no cause. Nine-tenths of the German people would never have consented to war had it been possible to avoid it without sacrifice of national honour. This was no longer the case after Russia had already begun the war against Germany.

Only if the chronological sequence of events, which is beyond doubt, is made clear can a non-party judgment on the guilt of one side or the other be pronounced.

From the above facts it is at once evident that the political platform which Prof. Noyes puts forward is not acceptable to us Germans either. In that platform it is mentioned how Austria was guilty and how Germany was alleged to be guilty, but not a word is said about the guilt of the Allies. Their guilt in relation to Russia was, however, gigantic. Why have the Allies the right to interfere in a quarrel between Austria and Serbia, and to attack Germany before she had even decided whether or not she would fight on the Austrian side?

Apart from the fact that Germany would have to concede a wrong in accepting Prof. Noyes' platform, she has in addition to submit to the decision of a World Court in the matter of the occupation of the Ruhr and other German territory! What is this World Court? It is France for the time being, for she has the power to which the other countries bow. What sort of decision this World Court would arrive at can be anticipated from its attitude in Upper Silesia and Memel. We have already been deceived twice by this World Court, and are again asked confidently to put our trust in its hands. One cannot expect a person who has been attacked, plundered and several times deceived to have any more faith in the world.

I more than doubt whether Prof Noyes is right in the assumption that the French oppose the admission of Germany to the League of Nations because they are suspicious of an attack on the part of Germany. That would not be a sufficient reason, even if the idea were not so absurd as it is at the present time. Even the most timorous Frenchman cannot suppose that the Germans would attack the French at the meetings of the League! It seems to me much more likely that it is their bad conscience which urges the French to obtain a confession of guilt on the part of Germany. It is quite clear that the World War was the fruit of forty years' agitation, kept up by the leading French politicians from the time of the last Franco-German War.

The question may be raised as to whether Germany was altogether innocent of causing the War. She was not, but her guilt was passive, not active. The

German Government, since the resignation of Bismarck, had convinced its enemies by its vacillating policy that now was the time to get even with Germany—the *parvenu* amongst European nations. That William II., in spite of occasional sabre-rattling, never contemplated an offensive war is clear to all our enemies. One may think as one likes about the man himself, but it must be conceded, in full justice, that he was always ready for peace; this he has proved more than once and even at the price of the dignity of the Empire. The guilt of the German Government is, therefore, the guilt of a man able to secure his house against burglars but unwilling to do so, thereby giving malefactors their opportunity. Hence the German people have the right to bring their late rulers to account but their enemies have not.—I am, Sir, etc., DR. P. FRITZSCHE

Leipzig.

May 25, 1924

PERSONAL AND OTHER ITEMS

Prof. H. B. Dixon has been elected president of the Manchester Literary and Philosophical Society.

The honorary degree of LL.D. will be conferred on Prof. F. Gowland Hopkins, F.R.S., and Emeritus Prof. Frankland, at the Degree Congregation of the University of Birmingham, on July 5.

The Franklin Institute of Philadelphia has presented, through the British Embassy in Washington, the Franklin medal and certificate to Prof. Sir Ernest Rutherford, F.R.S., in recognition of his researches in radio-activity.

It is announced that Mr. J. B. Coleman will retire shortly from his post as head of the chemical department of the Chelsea Polytechnic.

Mr. J. B. Speakman, M.Sc., has been appointed lecturer in textile chemistry in the University of Leeds, in place of Mr. E. A. Fisher, M.A.

Sir Charles Parsons has been re-elected president of the Institute of Physics for the forthcoming year.

Prof. J. C. McLennan, of Toronto University, has been elected president of the Royal Society of Canada.

Mr. B. Mead, a graduate of the Imperial College of Science and Technology, London, has joined the staff of the Research Laboratory for Applied Chemistry in the Massachusetts Institute of Technology.

The degree of D.Sc. in chemistry of London University, has been conferred on Mr. S. Sugden, of Birkbeck College.

We regret to announce the death of Sir Milton Sharp, chairman of the Bradford Dyers' Association. Sir Milton Sharp possessed a wide knowledge of the dyeing industry, both in this country and abroad, and during the war he rendered valuable service as a member of the committee on the manufacture of high explosives.

The death of Mr. John Sterry in Australia marks the passing of a well-known photographic experimenter. Mr. Sterry was the author of much work on the properties of the latent image, work for which he received the Progress Medal of the Royal Photographic Society in 1908.

Chemical Workers' Wages

The claim of the chemical trade workers for another penny an hour for day workers and three-halfpence for shift workers, and for week-end work to be paid at double instead of time and a half, has been heard in the Industrial Court. The Chemical Trades Joint Industrial Council, for the workers, claimed that the present wage was inadequate, discussed reductions in wages during the last two or three years, and suggested that the industry was financially able to meet the claim. For the employers, Mr. Lloyd Roberts, of Messrs. Brunner, Mond and Co., opposed the claim on the ground that concession of the claim would endanger the stability of the chemical industry and would react unfavourably on other industries. In addition, he said that foreign competition was severe, the employers were responsible to the shareholders and consumers as well as to the workpeople, and the existing rates of pay were reasonable. He also stated that if existing plant were employed to capacity 34,000 workpeople could be employed as against the 22,000 at present employed and covered by the claim. The award will be announced shortly.

Denatured Spirit

The Commissioners of Customs and Excise have given notice that all mineralised spirits made on and after May 1 must consist of:—90 per cent. plain British spirits, or unsweetened foreign spirits or rum; 9·5 per cent. methyl alcohol; and 0·5 per cent. crude pyridine; and must contain, in addition, 0·375 per cent. by volume of approved mineral naphtha or petroleum oil, and not less than 0·025 of an ounce of aniline dye (methyl violet) for each 100 gallons of spirits. Further regulations lay down specifications for the crude pyridine to be used, and require the provision of a tank of a minimum capacity of 10 gallons for storing the pyridine. In all other respects, the law and regulations governing the making of methylated spirits remain unchanged.

Chemical Warfare in Russia

According to the *Times* of May 22, a "Chemical Defence League" has been formed in Russia to organise the "fourth fighting service," to be known as the "Dobrokhim" (a word derived from the name "chemical volunteers)." The Soviet press states that the other fighting services will merely be mediums to bring the "Dobrokhim" in touch with the enemy.

New Italian Technical Journal

Under the title of "Revista Technica delle fermentazioni," Prof. G. Mezzadroli, of Bologna, has founded a review devoted to the scientific study of the fermentation industry, including the wine-making, distillation, beer, acetic acid, casein and cheese, retting and related industries. The yearly subscription is 30 lire, and the editorial secretary is Dr. G. Marenduzzo, Bologna (18), Via Toscana 301

The Kent Coalfield

The formal initiation of the sinking of a shaft at the Betteshanger colliery on May 20 marked an important step in the development of the Kent coalfield. According to *The Times*, this pit is the first of a series projected by Messrs. S. Pearson and Dorman Long, Ltd., who have acquired the mineral rights under, roughly, 60 of the 80 square miles in Kent, in which borings and sinkings indicate the existence of 1500 million tons of coal in seams 3 to 9 ft. thick at depths from 400 to 1000 yards.

REVIEWS

Oils, Fats, Waxes and Resins. By E. R. Bolton and R. G. Pelly. With a foreword by H.R.H. The Prince of Wales, K.G., and General Introductions by the Rt. Hon. Sir E. Geddes, G.C.B., and J. H. Batty. Pp. 275. London: E. Benn, Ltd., 1924. Price 21s.

Of the twelve volumes which are to constitute the Resources of the Empire series it is probable that none will be more useful to its own particular public than that now issued under the above title. Few only of those engaged in the various industries concerned with the preparation, refining and utilising of oils have more than a vague idea of their magnitude in the aggregate, and certainly the user of the finished products has little knowledge of their enormous importance as items of imperial commerce. The civilised and accessible parts of the Empire furnish oil-bearing seeds and prepared fats in quantities amounting to millions of tons, whilst the arctic circles are penetrated for supplies of whale and similar oils, and the virgin forests of our tropical colonies are made to yield their supplies of palm and many other oils. It is obviously impossible for the authors to have compressed into the space of a book of less than 300 pages all that is known about the various oils, fats, waxes and resins, but recognising the purpose of the series they have wisely restricted themselves to a statement of the outstanding characteristics, both technical and commercial, of the important articles of commerce which can be included under the very comprehensive title chosen for their volume.

The earlier pages are taken up by a brief, but nevertheless lucid, statement of the manufacture and refining of the various oils and fats, their physical and chemical characteristics being so summarised that the basis of the commercial valuation of the raw or finished products is readily understood.

From the succeeding pages, in which individual materials are dealt with, much is to be learnt of their origin and preliminary treatment. Indications are also given as to how supplies may be increased, but these are not given without a full and reasoned statement of the pitfalls that lie in the way of the unwary, especially those who have little realisation of the need for marketing to best advantage by-products as well as prime materials.

An important part of the volume is the summarised statement of the trade of the Empire, which is remarkably comprehensive and of the greater value in that mere statistics are relieved by comments, *e.g.*, on local conditions, which cannot fail to be of value to commercial men.

This is essentially a business man's encyclopædia, and must be of the greatest value to everyone connected with the industries with which it deals.

J. Allan

Clouds and Smokes: The Properties of Disperse Systems in Gases and their Practical Applications. By W. E. Gibbs, D.Sc. Pp. xiii + 240. London: J. and A. Churchill, 1924. Price 10s. 6d.

All chemists and technologists, and many other individuals, will find much of utility and interest in the volume on "Clouds and Smokes" by Dr. Gibbs. The author has produced within a comparatively small compass a very complete treatise upon disperse systems in which a solid or liquid substance is dispersed in gas-systems and termed by the author "Aerosols."

The book is divided into two parts, the first of which is mainly theoretical, whilst the second deals with the various practical aspects of the subject. The extent of the topics dealt with by the author is very wide, and includes industrial treatment of fumes and dusty gases, dust explosions, meteorological phenomena, the preparation of metallic powders, the production of metallic coatings, spray evaporation, and also the use of smoke in warfare.

The utility of the book is enhanced by a very complete bibliography which is included at the end of every chapter; in addition to this, the book is provided with a subject and name index.

There are a few misprints, as, for example, on page 1, in which the velocity of gaseous molecules is stated to be 10·4 cm. per second. This error is repeated again on page 41. On page 24 the statement is made that: "The presence of an electrical charge on the surface of a liquid opposes the surface tension and, therefore, diminishes the vapour pressure to an extent that is proportional to the fourth power of the drop." This is a loose statement which should be corrected in subsequent editions.

It is, of course, impossible for any author to be fully conversant with the large variety of topics which are dealt with and discussed in the volume, and the reviewer is not in agreement with all the statements made in the chapter upon the use of smoke in warfare. The major part of this chapter appears to be derived from the publication by Fries and West on Chemical Warfare. This gives the American viewpoint, which was not always in accord with the British. For example, the reviewer is very much inclined to doubt the formation of a true smoke from a mixture of chlorpicrin and phosgene as stated on page 230. Any liquid particles produced from this mixture are at best present for a very short period only, and this mixture behaves as a toxic gas and not as a smoke in the commonly accepted sense of the term.

COMPANY NEWS

CANADIAN CONSOLIDATED RUBBER CO., LTD.

The financial statement of the Canadian Consolidated Rubber Co., Ltd., shows that the net sales for the past year amounted to $14,590,433 as compared with $13,221,575 the previous year. Net income was $906,044 as compared with $132,262 in 1922 and $90,336 in 1921. Current assets on December 31, 1923, totalled nearly $7,000,000, while current liabilities were slightly over $550,000 as compared with $1,082,114 in the previous year. Bills payable were reduced from $459,000 to $7,000, while loans payable of $105,000 were entirely eliminated. After payment of preferred dividends the surplus for the year amounted to $696,044, equal to 24·81 per cent. on the $2,805,000 of common stock which is comparable with a deficit of $781,876 in 1922, and a deficit of $1,935,495 in 1921.

ROSARIO NITRATE CO., LTD.

The directors propose to pay a final dividend of 6 per cent., less tax, making 11 per cent., less tax, for the year, and to carry forward £29,179. This profit is arrived at after setting aside for depreciation £19,672 to cover the estimated value of raw material extracted from the grounds, and also for depreciation of plant and machinery. Oficina "Rosario de Huara" worked throughout the year; "Argentina" is being entirely reconstructed; and "Pintilla" is being dismantled. The previous accounting period was for 15 months to December 31, 1922, when the net profit was £25,966 and the dividend was 10 per cent., free of tax.

In 1923 the profit was £51,303, and £28,614 was brought forward.

FORTH GLASS WORKS

An extraordinary meeting has been called to discuss a resolution for the voluntary winding-up of this company, which was formed in 1920 in Glasgow with a capital of £60,000, of which £45,000 was issued in £1 shares. For last year the working showed an adverse balance of £12,630.

AGUAS BLANCAS NITRATE CO., LTD.

The net profit for 1923 was £21,330, to which is added £27,141, making £48,471 available. It was decided to distribute a final dividend of 50 per cent., less income tax, making 75 per cent for the year, and to carry forward £8,753. The company's oficina is working nearly at full capacity.

ANGELA NITRATE CO., LTD.

The accounts for 1923 show a net profit of £24,498 (£1071 in 1922), and a further dividend of 15 per cent. is proposed, making a total of 25 per cent. for the year (against 10 per cent.). £3350 is placed to amortisation of grounds reserve, leaving a balance (including £1005 brought in) of £4652 to be carried forward, subject to corporation tax. Profit has been taken on 123,698 metric quintals (22,452 metric quintals in 1922).

BRUNNER, MOND & CO., LTD.

At the annual general meeting on May 23, Mr. Roscoe Brunner, who presided, first referred to the death of Mr. A. Travers Hawes, an old director of the Castner Kellner Alkali Co., who joined the board in 1916. In discussing the balance-sheet (*cf. Chem. and Ind.*, May 23, p. 496), Mr. Roscoe Brunner said that sums advanced to subsidiary companies—Synthetic Ammonia and Nitrates, Ltd., and the Buxton Lime Firms, Ltd.—now appeared, not as debts owing, but as investments, an item which thus was increased by £1,140,000; debts owing were reduced by £1,639,000, and cash at bank was up by £537,000. The sum of £186,000 had been written off suspense account, which was used to keep the plant up to date, and £200,000 had been added to depreciation account. Judging from all indications, the outlook could be considered with confidence. The loss of £25,000 in the Japanese earthquake was suffered by the Japanese company, but increased trade promised to cancel the loss. It was not yet possible to say when the new Wallerscote works would begin to produce, but the works would be the "best in the world." Synthetic Ammonia and Nitrates, Ltd., began to produce in December, and the process was working so well that work was in hand for extending the plant and for the production of ammonia salts other than the sulphate, a salt which had met with great favour. The company's proposals for the reconstruction of the Magadi Soda Co. were still under consideration. Taxation was still too heavy, and the workers were asking for increased wages. Given relief from taxation, freedom from strikes, and more stiffness towards demands for higher wages, there would be an improvement in trade that would allow industry to pay those higher wages that would increase both consumption and trade.

Sir Alfred Mond, commenting on the reduced dividend, said the directors were conserving out of profits a large amount so that their great business might be maintained on sound lines. He then paid a high tribute to the staff of the Synthetic Ammonia works for overcoming the technical difficulties of the process in so short a time, an achievement which was also praised by Sir John Brunner.

The report and accounts were adopted, and the six retiring directors—Sir J. Brunner, and Messrs. A. Colegate, H. Glendinning, J. H. Gold, C. F. Poole and L. Solvay—were re-elected.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Geological Museum

Replying to Sir John Brunner, Mr. Trevelyan said that he was aware of the fact that the Geological Museum was overcrowded. Steps were being taken to put the Museum into constructional and decorative repair, but the Board of Education and the Committee of the Privy Council for Scientific and Industrial Research intended in due course to reconsider the Bell Committee's Report, which proposed to house the Geological Museum on a site near to the collections

of the Natural History and Science Museums.—(May 15.)

British Dyestuffs Corporation, Ltd.

In a written answer to Mr. Black, Mr. Webb stated that no reparation dyestuffs had been sold to the British Dyestuffs Corporation for re-working or disposal, with the exception of a certain quantity of indigo requisitioned under a special arrangement which was in operation for a short time between the Board of Trade, the principal consumers of indigo in the textile trades, and the Corporation. The prices charged for reparation dyestuffs were fixed by the Board of Trade from time to time with the help of an informal committee consisting of two representatives of the Colour Users' Association, and two representatives of the British Dyestuffs Corporation as the Board's agents. The supplies of dyestuffs were requisitioned by the Board after consultation with representatives of the British makers and of the consumers, and had been confined, so far as practicable, to products not competitive with British products. The amount paid to the British Dyestuffs Corporation in the year ended March 31, 1924, for commission and all other charges was £40,070, representing commission on sales during the year amounting to £343,600, and not on the value of dyestuffs received, together with certain expenses chargeable to the Board of Trade.—(May 20.)

Safeguarding of Industries Act

Replying to Mr. D. G. Somerville, Mr. Webb said that the operation of the depreciated currency provisions of Part II of the Safeguarding of Industries Act was specially limited to three years, and could not be continued after August 19 next without fresh legislation. The decision not to introduce such legislation was taken by the Government after full consideration of all the circumstances, and he did not feel that an inquiry into the anticipated effect of the cessation of these provisions, on the expiry of the period for which they were enacted, would serve any useful purpose.

In answer to Mr. Kean Mr. Alexander replied that he could not give details of an individual works, but he was informed that the number of persons employed in making arc-lamp carbons in April of this year was approximately double that of April, 1921. The output of the factory included various types of carbons which were not covered by the Safeguarding of Industries Act.—(May 20.)

The 1851 Exhibition (Surplus Income)

Replying to Sir F. Hall, Mr Graham said that the Commissioners of the Exhibition of 1851 possess, as a result of judicious investment of the original surplus funds of that exhibition, an estate now valued at approximately £500,000, with a net income of over £20,000. This income was entirely devoted to scholarships and grants to research students, nearly half of which are allocated to research students from overseas and to industrial bursaries. The Commissioners had no objection to their accounts for the year ending December 31, 1923, being laid before Parliament with a memorandum explanatory of the activities of the Royal Commission past and present. This would accordingly be done.—(May 26.)

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40%, tech. ..	£23 10s. per ton.
Acid Hydrochloric ..	3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£19 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid.
Sod. Bichromate.. ..	4½d. per lb.
Sod. Bisulphite Powder 60/62%..	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton. d/d
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide ..	3s. 9d. per lb.
Carbon Bisulphide ..	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer.
Carbon Tetrachloride ..	£56 per ton, drums free.

Chromium Oxide, green ..	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	43s. 6d. per cwt., barrels free.
Lead Hyposulphite ..	7¼d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride ..	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb. Much dearer, following rise in quicksilver.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s.—5s. 3d. per gall. 60% O.P. market stiffer.
Solvent	5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead ..	£49 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—7d. per lb. Better inquiry at reduced price.
Crude 60's	1s. 9d.—1s. 10d per gall. Market rather flat.
Acid Cresylic, 97/99 ..	2s. 1d.—2s 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor ..	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole 90%	1s 5½d. per gall.
Pure .. .	1s 10d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s 3d. per gall.
Creosote—	
Cresylic 20/24% ..	9d.—9½d. per gall. Few inquiries.
Middle Oil .. / Heavy .. .. / Standard Specification	7½d.—9d. per gall. according to grade and district. Fair demand.
Naphtha—	
Crude	8d.—9d. per gall. Market not quite so firm.
Solvent 90/160 ..	1s. 4d.—1s. 5d. Market not quite so firm.
Solvent 90/190 ..	1s. 2d.—1s. 3d. Market not quite so firm.
Naphthalene Crude—	
Drained Creosote Salts	£6—£6 10s. Demand falling off.
Whizzed or hot pressed	£9—£12 per ton More inquiry.
Naphthalene—	
Crystals and Flaked ..	£17—£18 per ton.
Pitch, medium soft ..	52s. 6d.—57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt.
Pyridine—90/160 ..	21s. 6d.—22s. per gall. Demand well maintained.
Heavy ..	12s.—12s. 6d. More business passing.

INTERMEDIATES AND DYES

Business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 6d. per lb.
Acid H.	4s. 4d. per lb. 100% basis d/d.
Acid Naphthionic ..	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 2d.—1s. 3d. per lb. Steady demand.
Acid Sulphanilic ..	10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C. ..	4¾d.—5½d. per lb. Demand moderate.
m-Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethyaniline	2s. 4d per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d.
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine ..	1s. 4½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5½d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. per lb. 100% basis d/d.
Nitronaphthalene ..	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	4s. 2d. per lb. d/d.
p-Phenylene Diamine ..	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.

p-Toluidine ..	.. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £49 per ton.
Acid, Acetyl Salicylic	.. 3s. 3d.—3s. 5d. per lb. In good demand.
Acid, Benzoic B.P.	.. 3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P.	.. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst.	.. 7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic ..	.. Prices quoted from 2s. 2d. per lb. down to 1s. 11d. for ton lots.
Acid, Tannic B.P.	.. 3s. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 3d. per lb. for quantity. Stocks are small.
Amidopyrin ..	.. 13s. 6d per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. per oz. for English make.
Barbitone	.. 15s. 6d. per lb. Quiet market.
Benzonaphthol ..	.. 5s. 6d. per lb. Small inquiry.
Bismuth Salts ..	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
„ Citrate ..	.. 11s. 4d.—13s. 4d. „
„ Salicylate	.. 10s. 2d.—12s. 2d. „
„ Subnitrate	.. 10s. 9d.—12s. 9d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Prices advanced. Raw material much dearer. Higher prices expected when present stocks of foreign material are cleared.
Potassium ..	.. 11d. per lb.
Sodium ..	.. 1s. „
Ammonium ..	.. 1s. 1d. per lb.
Calcium Lactate	.. Demand not very active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate ..	.. 3s. 7d. per lb., duty paid.
Chloroform ..	.. 2s. per lb. for cwt. lots. Market more active. Makers busy.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £57 per ton, ex works. English make.
Glycerophosphates —	Fair business passing
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s „
Potassium, 50%	.. 3s. 6d. „
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 12s. per lb. for cwt. lots. Supplies not plentiful.
Hexamine ..	.. 3s. 6d. per lb. for English make. Imports cannot be made at this figure.
Homatropine Hydrobromide	.. 30s. per oz.
Hydroquinone ..	.. 4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb lots.
Potassium ..	.. 4s. 1d. per lb
Sodium	.. 4s. „
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 62s. 6d. per lb.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials ..	.. Market rather flat, but prices unchanged.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. „
White precip. ..	.. 4s. 7d.—4s. 8d. „
Calomel ..	.. 3s. 11d.—4s. „
Methyl Salicylate	.. 2s. 3d.—2s. 9d. per lb. for carboys. A slightly better market.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 3s. 6d. per lb., Better inquiry.
Paraldehyde ..	.. 1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin ..	.. 6s. per lb. Somewhat cheaper.
Phenazone ..	.. 7s. 3d. per lb. for cwt. lots. Quiet.
Phenolphthalein ..	.. 6s. 9d.—7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 88s. per cwt, less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 8d.—2s. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal ..	.. 8¾d.—9d. per lb. carriage paid.
Commercial ..	.. 8d.—8¼d. per lb. carriage paid.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 6d. per lb.
Saccharin	.. 63s. per lb., in 50-lb. lots.
Salol	.. 4s. per lb. Very quiet.
Silver proteinate	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. In steady demand for good qualities.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite— Photographic ..	.. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet

Sod. Salicylate ..	.. Market easier. Powder 2s. 4d.— 2s. 6d. per lb. Crystal at 2s. 6d.—2s. 8d. per lb. Flake 2s. 9d.—3s. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	.. 15s per lb. for good white crystal from ajowan seed. Very firm and scarce.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.		
Aubepine	.. 14s. 6d. per lb.		
Amyl Acetate ..	.. 2s. 9d.	,,	
Amyl Butyrate ..	.. 7s. 3d.	,,	
Amyl Salicylate ..	.. 3s. 3d.	,,	
Anethol (M.P. 21/22° C.)	4s. 6d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d.	,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d.	,,	
Benzaldehyde free from Chlorine ..	.. 3s. 6d.	,,	
Benzyl Benzoate	.. 3s. 6d.	,,	
Cinnamic Aldehyde Natural.. ..	.. 15s. 6d.	,,	
Coumarin ..	.. 20s.	,,	
Citronellol ..	.. 16s.	,,	
Citral	.. 10s.	,,	
Ethyl Cinnamate	.. 15s.	,,	
Ethyl Phthalate ..	.. 3s. 3d.	,,	Reduced.
Eugenol	.. 11s.	,,	
Geraniol (Palmarosa)	.. 35s.	,,	
Geraniol	.. 11s.—18s. 6d. per lb.		
Heliotropine ..	.. 6s. 6d. per lb.		Reduced.
Iso Eugenol ..	.. 15s. 9d.	,,	
Linalol ex Bois de Rose	.. 28s. 6d.	,,	Reduced.
Linalyl Acetate ..	.. 28s. 6d.	,,	Reduced.
Methyl Anthranilate	.. 9s. 6d.	,,	
Methyl Benzoate	.. 6s.	,,	
Musk Ambrette ..	.. 48s. 6d.	,,	Reduced.
Musk Xylol ..	.. 16s. 6d.	,,	Reduced.
Nerolin	.. 4s.	,,	
Phenyl Ethyl Acetate	.. 12s. 6d.	,,	
Phenyl Ethyl Alcohol	.. 16s.	,,	
Rhodinol	.. 57s. 6d.	,,	
Safrol	.. 1s 10d.	,,	
Terpineol	.. 2s. 9d.	,,	
Vanillin	.. 25s. 3d.—26s. 6d. per lb.		

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 15s. 6d. per lb.		
Anise Oil	.. 3s. per lb.		
Bergamot Oil ..	.. 18s. 6d. per lb.		
Bourbon Geranium Oil	.. 36s. 6d	,,	Advanced.
Camphor Oil ..	.. 75s. per cwt.		
Cananga Oil, Java	.. 10s. 6d. per lb.		
Cinnamon Oil, Leaf	.. 6½d. per oz.		
Cassia Oil, 80/85%	.. 9s. 3d. per lb.		
Citronella Oil—			
Java 85/90% ..	.. 6s. per lb.		Again dearer.
Ceylon	.. 3s. 9d. per lb.		
Clove Oil	.. 7s. 6d.	,,	
Eucalyptus Oil 70/75%	.. 2s. 2d.	,,	
Lavender Oil—			
French 38/40% Esters	.. 57s. 6d. per lb.		
Lemon Oil ..	.. 3s. 2d. per lb.		
Lemongrass Oil ..	.. 3d. per oz.		
Orange Oil, Sweet	.. 13s. 9d. per lb.		
Otto of Rose Oil—			
Bulgarian ..	.. 27s. 6d. per oz.		
Anatolian ..	.. 23s. 6d. per oz.		
Palma Rosa Oil ..	.. 19s. per lb.		
Peppermint Oil—			
Wayne County	.. 21s. 6d. per lb.		
Japanese ..	.. 16s. 3d. per lb.		
Petitgrain Oil ..	.. 10s. per lb.		
Sandal Wood Oil—			
Mysore	.. 26s. 6d. per lb.		
Australian ..	.. 21s. per lb.		

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 10th; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on June 5th.

I.—Applications

Atkinson, and Powdered Fuel Plant Co. 11,684. *See* II.

Griscom-Russell Co. Evaporator. 11,692. May 12. (U.S., 12.6.23.)

Hille, Procter, and Young. Pulverisation of substances. 12,160. May 17.

Pollak. Removing liquid medium from emulsion colloids. 12,033. May 15. (Austria, 22.6.23.)

Stern. Treating liquids with gases. 12,096. May 16.

Wilson and Young. Drying, dyeing, vulcanising, etc. 11,763. May 12.

I.—Complete Specifications Accepted

14,383 (1923). Allen and Co., Ltd., and Coles. Grinding or crushing mills. (215,595.)

2355 (1924). Koppers Coke Oven Co., Ltd. Apparatus for washing liquids with liquids. (210,774.)

II.—Applications

Atkinson, and Powdered Fuel Plant Co. Drying and pulverising coal. 11,684. May 12.

Chambrier, de. Process for recovery of crude oil. 12,132. May 16.

Donald. Drying peats etc. 11,884, 11,980. May 14 and 15.

Gelsenkirchener Bergwerks-Akt.-Ges. Abteilung Schalke. Process for obtaining light oils and gaseous constituents from distillation products. 11,950. May 14. (Ger., 16.5.23.)

Ges. fur Chemische Produktion, and Clemm. Manufacture of decolorising charcoal. 11,847. May 13. (Ger., 14.5.23.)

Humphreys and Glasgow, Ltd. (Fulweiler). 11,751. *See* XXIII.

Koppers. Coke ovens. 12,209. May 17. (Ger., 13.6.23.)

Misch. Gas-producer. 11,720. May 12.

Naamlooze Vennootschap Philips' Gloeilampenfabrieken. 11,753. *See* X.

Rider, and Woodall-Duckham, Ltd. Manufacture of water gas. 12,208. May 17.

Seigle. Liquid fuels. 12,021. May 15. (Fr., 19.5.23.)

Sulfrian. Production of combustible gases. 11,939. May 14

Tinker. Production of petrol. 12,207. May 17.

II.—Complete Specifications Accepted

444 (1923). Koppers Co. Regenerative retort oven batteries. (191,393.)

15,812 (1923). Withers (Vere n. Kolenmaatschappijen). Apparatus for refining or concentrating coal slimes and ores in accordance with the froth flotation process. (215,615.)

3,250 (1923). Ketterer. Recovery of carbon dioxide from waste gases and the like. (204,063.)

III.—Application

Moore. Purification of creosote oils etc. 12,179. May 17

IV.—Application

Farbwerke vorm. Meister, Lucius, u. Brüning. Manufacture of vat dyestuffs. 11,859. May 13. (Ger., 25.6.23.)

.—Applications

Bergen, van. Manufacture of viscose threads, films, etc. 11,775. May 13. (Holland, 15.5.23.)

Carpmael (Farbenfabriken vorm. F. Bayer und Co.). Process for protecting wool, fur, etc. from moth. 11,749. May 12.

Cross, and Viscose Development Co. Application of cellulose hydrates. 11,723. May 12.

Hands. Non-inflammable sheets etc. of cellulose. 12,173. May 17.

Silbermann. Production of pure cellulose fibres etc. 12,118. May 16.

.—Complete Specification Accepted

2112 (1923). British Celanese, Ltd. Manufacture or treatment of threads of artificial filaments. (215,417.)

I.—Application

Wilson and Young. 11,763. *See* I.

I.—Complete Specification Accepted

29,913 (1923). Callebaut and Blicquy. Hank-dyeing machine. (215,672.)

II.—Applications

Brunner, Mond and Co., Ltd. Process of making ammonium by catalysis. 11,655. May 12. (U.S., 12.5.23.)

Ges. fur Chemische Produktion, and Schmidt. Obtaining hydrochloric acid free from arsenic. 11,846. May 13. (Ger., 14.5.23.)

Humphreys and Glasgow, Ltd. (Fulweiler). 11,751. *See* XXIII.

Metal Traders Technical, Ltd. Process of concentrating sulphuric acid. 11,676. May 12. (Ger., 11.5.23.)

II.—Complete Specifications Accepted

1619 (1923). West and Jaques. Manufacture of ammonia compounds. (215,170.)

9405 (1923). Cassale. Synthetic production of ammonia. (19.,655.)

III.—Complete Specification Accepted

19,182 (1923). General Electric Co., Ltd. Production of transparent bodies from opaque substances, especially oxides. (211,824.)

X. Application

Bureau d'Organisation Economique, and Soc. Anon. de Ciments Français. Manufacture of cement. 12,058. May 16. (Fr., 9.4.24.)

X.—Complete Specification Accepted

3722 (1923). Naaml. Ve. noot. Glasfabriek "Leerdam." Process for preparing stone-like material. (201,880.)

X. Applications

Cothay. Gravity concentration of ores. 11,965. May 14.

Marks (Electro-Metallurgical Co.). Metal treating compositions. 11,737. May 12.

Naamlooze Vennootschap Philips' Gloeilampenfabrieken. Manufacture of tungsten filaments. 11,753. May 12. (Holland, 17.5.23.)

X. Complete Specifications Accepted

30,772 (1922). Coley. Reduction of ores, oxides, and the like. (215,400.)

5727 (1923). Jackson (Ossa). Treatment of copper ores. (215,139.)

6313 (1923). Benjamin. Furnaces for melting and casting. (21.,495.)

11,669 (1923). Parkes, Ltd., Sharpe, and Hartland. Grinding mills. (215,555.)

15,812 (1923). Withers (Vereen. Kolenmaatschappijen). *See* II.

16,057 (1923). Electro-Metallurgical Co. Heat treated chromium steel, and processes of making same. (210,388.)

18,009 (1923). General Electric Co., Ltd. Preparation of ductile wire of tungsten or the like. (209,025.)

XI.—Application

Banyay. Electric accumulators. 12,057. May 16.

XI.—Complete Specifications Accepted

5872 (1923). Heis and Jezler. Treating substances in an electric field. (194,293.)

31,979 (1923). Heis and Jezler. Treating substances in an electric field. (215,701.)

XII.—Application

Lever Bros., Ltd., and Tyrell. Manufacture of dry soap. 11,757. May 12.

XII.—Complete Specification Accepted

29,534 (1923). Soc. Anon. Acetoleum. Extracting oil from grains etc. by solvents. (207,542.)

XIII.—Complete Specification Accepted

25,274 (1923). Deutsche, Thorn, and "Amalith" Chemische Industrie Ges. Hardening products of condensation from phenols and aldehydes. (207,790.)

XIV.—Application

Wilson and Young. 11,763. *See* I.

XIV.—Complete Specification Accepted

3865 (1924). Naugatuck Chemical Co. Compounding of rubber and similar materials. (211,494.)

XVI.—Complete Specification Accepted

4270 (1923). Christensen. Production of fertilising-material. (215,463.)

XIX.—Applications

Braeutigam, and Weber A.-G. Disinfectant. 11,942. May 14. (Ger., 14.5.23.)

Ges. fur Chemische Produktion, and Deutsch. Elimination of iron from water. 11,845. May 13. (Ger., 14.5.23.)

XIX.—Complete Specifications Accepted

345 (1923). Fry. Disposal of industrial wastes. (215,410.)

3545 (1923). Agopian. Process for obtaining vitamines. (193,831.)

XX.—Application

Portratz. Production of isotonic solutions for treatment of infectious diseases. 11,728. May 12.

XXI.—Application

Christensen. Manufacture of multicolour screens. 11,963. May 14. (Ger., 1.6.23.)

XXIII. Applications

Cirio Co., Ltd. (Signorini). Apparatus for determining specific gravity etc. 11,857. May 13.

Humphreys and Glasgow, Ltd. (Fulweiler). Determination of hydrogen sulphide in gas. 11,751. May 12.

GENERAL NOTES

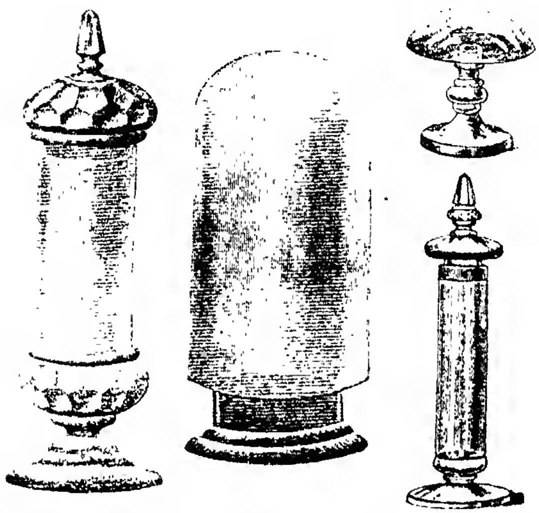
Official Trade Intelligence.

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department, and quoting the specific reference number:—*Canada*: Cutlery, crockery (581); *Finland*: Chemicals (589); Oils (590); *France*: Copra, groundnuts (593); Tinplate, sulphate of copper (594); *Germany*: Silk, electroplate (597); *Netherlands*: Copper sheets, enamelware and cutlery (604); *New Zealand*: Crockery (585); Microscopes (918/8/F.G./C.C./2); *Palestine*: Hardware (586); *Rumania*: Galvanised iron wire (13,120/F.E./E.C./2); *South Africa*: Iron (587); *Sweden*: Silk (607); *Turkey*: Skins (611); Leather, hides (612).

Trade Information

Photography has become so usual a feature of modern life that few pause to think of the scientific work that lies behind so much technical excellence. Of this excellence no little share is due to the efforts in deed and word of Burroughs Wellcome and Co., who have now added an excellent and artistic booklet entitled "Foresight in Photography" to their publications. On the cover is a reproduction of Commander Wild in the crow's nest of the "Quest," and this is ingeniously used throughout the booklet as a text to encourage the photographer to "look out" and exercise prevision in his work. A nautical flavour is pleasantly perceptible in the directions for the exposure, development and after-treatment of negatives by means of "Rytol" developer and other "Tabloid" photographic chemicals. An interesting feature is the inclusion of an illustration showing the effects of chromium intensification and of the possibilities of subsequent modification by treatment with reducers in various ways. A remarkably up-to-date table—it even includes the new Wellington "Spectrum" plate—is given showing plates and films grouped according to speed of development. One cannot but commend this advocate of sound methods to all photographers. Copies can be obtained free of charge from Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C. 1.

Show Jars are products which are often rather neglected. It is occasionally forgotten that, whilst such a jar is primarily a container, it should also provide a suitable setting for its contents, and thus should be designed with thought for its esthetic effect. No such reproach can be levelled at the



show jars made by the Edinburgh and Leith Flint Glass Company, whose products, some of which are illustrated below, are brilliant in appearance and tasteful in design, as can be seen by those who visit the British Empire Exhibition.

Space is available to illustrate but a few of the products of the Edinburgh factory, whose output includes a wide variety of round and oval jars stoppered or with ground plate covers, inverted round, and conical bottles, cylindrical bottles with cut-glass stoppers, and other types to suit all purposes. The firm also supplies all types of chemical apparatus, such as resistance glass beakers and flasks, graduated measures, as well as microscope slides and cover glasses.

PUBLICATIONS RECEIVED

The Manufacture of Paint. By J. Cruickshank Smith, B.Sc. Third and enlarged edition. Pp. xvi+306. London: Scott, Greenwood and Son, 1924. Price 12s. 6d.

Chemistry for Dental Students. By H. Carlton Smith, Ph.G., and R. M. Smith, A.B. Vol. I, Qualitative Analysis and Dental Metallurgy, pp. vi+186, and Vol. II, Organic and Physiological Dental Chemistry, pp. iv+320. Fourth edition, revised and enlarged. London: Chapman and Hall, Ltd., 1923. Price Vol. I, 12s. 6d.; Vol. II, 17s. 6d.

Forty-eighth Annual Report of H.M. Inspectors of Explosives, being their Annual Report for the Year 1923. Explosives Acts, 1875 (38 Vict. c. 17) and 1923 (13 and 14 Geo. 5). Pp. 50. H.M. Stationery Office, 1924. Price 1s. net.

Report on the Commercial and Industrial Situation in Hungary, dated February, 1924. By R. J. E. Humphreys. Department of Overseas Trade. Pp. 18. H.M. Stationery Office, 1924. Price 1s. 6d.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, APRIL 4, 1924 No. 14

EDITORIAL

THE discussions on chemical co-operation which recently took place at various local sections of the Institute of Chemistry provide a number of useful ideas and suggestions. A good many of these depend on the acquisition of a Chemistry House and many formal and informal meetings are now being held to investigate the merits of particular schemes and particular sites. Some of the possibilities of co-operation are independent of the existence of a London mansion containing the headquarters of the various societies. Throughout Great Britain there are local sections of two or three distinct societies, each local section having a large committee, some honorary officials and meetings where interesting chemical communications are read. He would be an acute man, with a nice sense of discrimination, who could tell from reading a report of a local section paper whether it had been read before the Institute, the Society of Chemical Industry, the Institute of Metals or some other body. It would be a highly irregular proceeding for some ambitious local section to appoint one joint committee of two or three of these societies, with one joint honorary secretary, eight or ten joint meetings a year and some scheme of joint reporting, joint publication and sharing of expenses. We cannot conceive any well-drawn rules which would permit such a proceeding, and it would not only be irregular but undignified. But we are of opinion that, but for an unqualified respect for rules—the result of a training which some chemists consider almost criminal—we should, if actively engaged in the work of the Herefordshire local section, make the experiment, treating the consequences in the manner advocated by Lord Milner. Is there a local section of the Great and Little Cumbraes and the adjacent islands of Great Britain and Ireland?

* * *

The Referee's Award on the inclusion of "Rongalite," a formaldehyde sulphoxylate, in the Safeguarding of Industries Act, 1921, has now been published. The Award refers to an article which appeared in this Journal on pages 5, 117 and 169 last year, and the learned Referee has incidentally pointed out that the statement in the article that he decided that calcium carbide was not synthetic is wholly inaccurate. We know ourselves from bitter experience how easy it is to make such inaccurate statements and how fallacious is the memory as to quotations unless the wording be verified almost immediately beforehand. Wondering whether Sir William Pope or ourselves had made this slip and fearing the latter, we have refreshed our memory by reading again the article, and with humility and diffidence we suggest that the learned Referee himself is under some slight misapprehension. The whole tenor of the Calcium Carbide articles is an argument that calcium carbide is a synthetic organic chemical and that the Referee's decision that it was not so was inaccurate. It is true that Sir William Pope first showed that it was organic and went on to argue that calcium carbide is not only an organic chemical but is also a synthetic organic chemical. This we suppose was to satisfy our readers that it would not have been possible for the Referee had he considered calcium carbide to be organic to have excluded it on the ground that in any case it was not synthetic. A careful search through the article has failed to disclose a statement that the Referee decided that calcium carbide was not synthetic. It is interesting to notice that chemical terms are now for some purposes being defined by legal minds. All definitions of any value are rigid; it is frequently of no consequence that they are logical. If chemists do not frame their own definitions or adopt some unanimous views of the meaning of the words they employ, they lay themselves open to having definitions thrust upon them by lawyers. The Federal Council, which has hardly anything to do except trying to raise funds for Chemistry House, to select a suitable site, to foster co-operation between some bodies who have as yet only elementary ideas of it, to propound a satisfactory scheme for the dyestuffs industry here and to assist in preparing for the Copenhagen meeting, might profitably spend a week-end at Chequers or some other country house and frame

half-a-dozen definitions to start with. No definition of an "organic" chemical will satisfy everybody. A definition could be framed which would now satisfy 60 per cent. of the chemists of this country, and if this were adopted each year the percentage would slightly grow until the non-conformists would on analysis reveal merely "trace."

* * *

The letter from Mr. N. K. Smith, in a recent number of this *Journal*, on the subject of the review of a recently published book, raises some interesting and difficult points. If a book is in the opinion of the reviewer good, it is worth while devoting a certain amount of space to a discussion of it, and to the explanation of errors and doubtful passages. If the book is in the opinion of the reviewer bad, the space available for the review is necessarily restricted. If a number of errors be mentioned as instances, unless ample space is taken up, the result is unsatisfactory both to the author and the readers. In the particular case Mr. Smith refers to, the reviewer originally wrote a much longer and detailed review, and it was at the request of the editor that his review was curtailed and left in very general terms. If we had sufficient space, nothing would afford us and our readers greater satisfaction that the exposure of a number of errors, the true explanation of the facts and the proper deductions to be made therefrom. No one has read Macaulay's review of Croker's Boswell without enjoyment and profit, and most of our readers are no doubt familiar with this instance. But how much time and space is involved! The practice of this journal is to be careful in the choice of reviewers, to afford as much space as possible—too often inadequate—for a good book and less space for a book which does not attain that standard. Only in the case of good books is it worth while to point out errors, and even then not errors which are obvious to everyone who reads the book. We are expressing no opinion as to the particular book in question; we have not read it. From the opinion of the reviewer, it seemed to fall into the class of books for which we cannot afford a column for a review, and we accordingly invited the reviewer to curtail his observations, and we must ourselves be saddled with the blame, if any, for this proceeding.

* * *

Cynics may shake gloomy heads over the fact that the announcement of the "isolation of vitamins," by Dr. W. Eddy, of Columbia University, was made in the issue of the *Times* dated April 1. The statement runs that the "new material is proved to be definite, chemical and individual, . . . is crystalline, possesses a definite melting point of 233° C., and . . . behaves like [illegible] Further, it contains "43 per cent. [illegible] per cent. hydrogen, about 25 per cent. nit[illegible] 24 per cent. oxygen," and "is present [illegible] growing yeast in the proportion of one part in 40,000." Prof. Drummond will doubtless be pleased with the spelling of "vitamin," but we wonder what he thinks of this "definite, chemical and individual" body, with its approximate content of nitrogen and oxygen.

EVAPORATING AND DRYING PLANT

PART II

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

The term drying is used, with few exceptions, in industrial work, to denote the removal of small quantities of liquid, usually water, from a substance or structure. The method by which this liquid is removed will naturally vary with the substance being treated. Drying may be effected either by chemical action, by adsorption, by mechanical means, or by the addition or removal of heat.

Chemical Action

When water is to be removed from a substance by chemical means, this may be done by effecting its decomposition by bringing it into contact with such

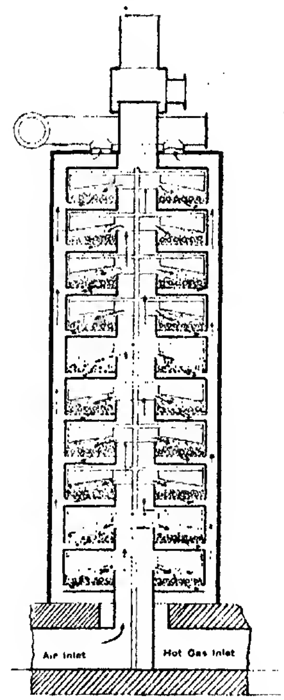

Fig. 1

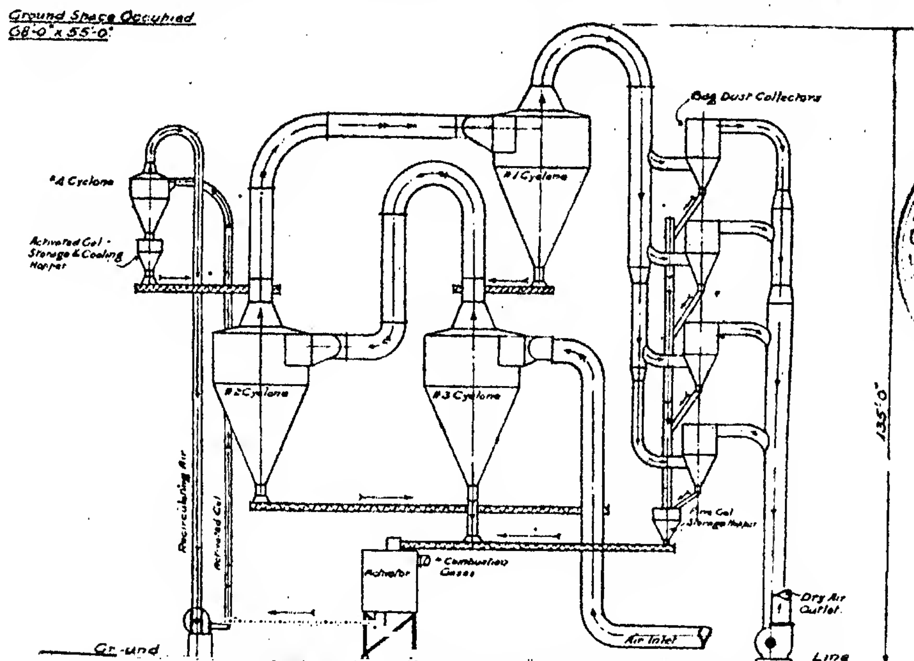
substances as metallic sodium, the carbides, and the nitrides, or by drying agents such as calcium chloride, lime, sulphuric acid, etc. For drying gases on a large scale, calcium chloride is employed, and, since 1880, various large-scale plants using calcium chloride have been designed. Daubine and Roy have designed such a plant which is capable of treating 30,000 cubic metres of air per hour. It consists (Fig. 1) of a cylindrical shell, inside which are ten trays, each containing a layer of calcium chloride, 24 cm. thick. Each tray is also fitted with a cooling coil. The air to be treated enters at the bottom of the cylinder, and is then admitted either to a central distribution tube, or to the annulus formed by the outer wall of the unit and the outer walls of the closed

trays containing the calcium chloride. In the first type of unit the air passes from the central shaft, through ports, into the closed trays, and then downwards through the mass of calcium chloride. After its passage through the mass, the dried air flows into the annulus, which is connected with the delivery pipe of the unit. In the second type, the air, entering through the annulus, passes upwards through the bed of calcium chloride, and is collected in the central tube, which in this case is attached to the outlet pipe. Provision is made whereby hot gases can be passed through the layers, to regenerate the calcium chloride. For continuous working, therefore, the plant consists of three such units, one being used to dry the air, whilst the calcium chloride is being regenerated by hot gases in the second, and cooled by the coils in the third.

Adsorption

In this type of drying the moisture is removed by being adsorbed and condensed within a structure containing ultra-microscopic pores, although these adsorbed vapours may be at temperatures and pressures considerably above their liquefaction point. Such natural substances as bauxite, clay, charcoal, etc. after activation, possess this property in varying degrees. An artificially prepared adsorbent is silica gel, which is the substance used for drying air in the plant illustrated diagrammatically in Fig. 2. In this plant the silica gel is fed into the current of air leaving cyclone 2, and is carried by this air into cyclone 1. Here the gel, having adsorbed the moisture, falls into the bottom of the cyclone, and is then transferred by a worm conveyor, and discharged into the outlet pipe from cyclone 3, where it meets with a partially dried current of air, which carries it into cyclone 2, where separation again takes place. The gel which collects at the bottom of this vessel, is carried by a conveyor, and discharged into the inlet pipe to the plant. The incoming untreated air carries this gel into cyclone 3, in the bottom of which the gel ultimately collects. From this vessel the gel is carried to the activator for heat treatment, after which it is again admitted to the plant. The air, after passing in turn through the cyclones 3, 2, 1, is discharged into a battery of bag dust collectors, which remove any gel which has been brought over by the dried air. Plants of the type illustrated are capable of handling large quantities of air such as would be required in blast-furnace work. Where small quantities of air have to be dried, the static type of plant is used. In this the air passes through a bed of silica gel, which surrounds a number of parallel tubes, fixed at their ends to two tube plates attached to the ends of the containing vessel. When drying is in progress, water is circulated through the tubes, which are also used to carry the hot gases employed during the reactivation period. This plant consists of two vessels, which, working alternately, produce a continuous supply of dried air. From tests made on a plant capable of handling 100 cb. ft. of air per minute, it was found that from 91 to 98 per cent. of the moisture was removed from the air, and that the temperature of the entering air could be varied from 53° to 107° F, without



Silica-gel Air-Drying Plant by the Kestner Evaporator and Engineering Co., Ltd.

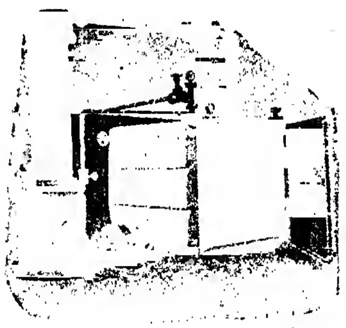
Fig. 2

causing the percentage of moisture removed to fall below that stated above.

Under the heading of mechanical separation can be included the removal of moisture from spongy materials, by compression in hydraulic or other presses, as well as the use of centrifugal machinery.

Addition or Removal of Heat

Drying by the removal of heat is practically confined to the treatment of gases, the temperature being reduced until the water vapour is converted into ice, which can be easily removed. Sometimes, however, this method, in conjunction with centrifugal separation, is employed in the treatment of delicate liquids, such as fruit juices. When a solid is heated, the outer layers of water which it contains are evaporated, and, owing to the difference in concentration between the outer layers and the centre, diffusion of the water takes place from the interior to the surface of the body. For drying to be continuous, therefore, it is essential that the rate of diffusion of the water through the material shall equal the rate of evaporation of the water from the surface of the substance. Sometimes the rate of diffusion is the controlling factor in drying, and, if this is the case, if the rate of evaporation from the surface exceeds the rate of diffusion through the material, cracks are liable to be produced on the surface of the material. With fibrous materials on the other hand, the moisture on the surface layers is usually replaced as quickly as it is removed, and then the rate of drying is directly dependent upon the rate of surface evaporation obtainable.



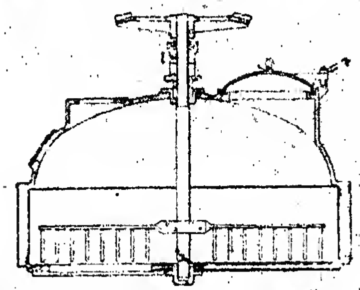
Vacuum Shelf Drier by F. Shaw and Co.

Fig. 3

The surface evaporation itself is a diffusion of water vapour through a relatively stationary film of air in contact with the surface, and then dispersion of the vapour by convection into the surrounding atmosphere. Naturally the thickness of this air film will affect the rate of evaporation, which will also be directly affected by the exposed area of the material, and the difference in pressure between water at the temperature of the surface of the film in contact with the material and the partial pressure of the water vapour in the surrounding air. Since the vapour pressure at any temperature over two non-miscible substances equals the sum of their partial vapour pressures, whilst, if the substances are miscible the vapour pressure in the liquid will be lowered, it follows that, other factors remaining constant, the rate of drying in the second case will be less than the rate of drying in the first.

Discontinuous Driers

One of the earliest forms of drying plant consists of a well-ventilated chamber, upon the floor of which the goods to be dried were laid. Sometimes the floor was made of iron plates, and was heated from underneath either by a number of small fires placed at different points or by metal pipes which carried the flue gases produced by a single furnace, and so distributed the heat more uniformly over the floor space.



Johnston Drier by Manlove, Alliott and Co., Ltd.

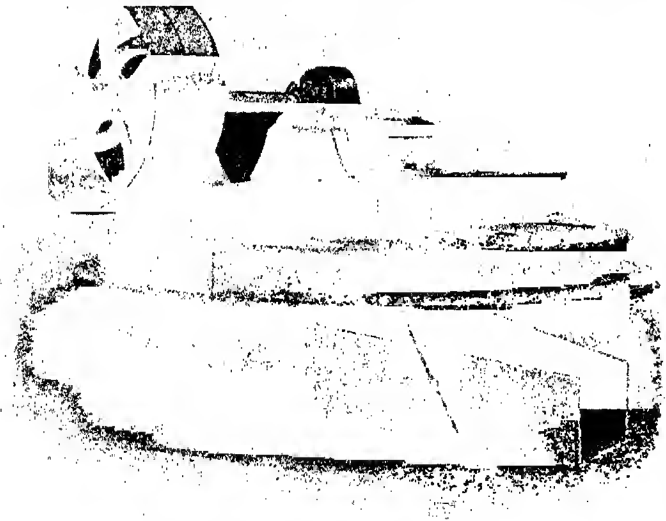
Fig. 4

When air inlets are provided in the floor, these are usually so arranged, that the air, before entering the chamber, is heated by passing round the pipes carrying the flue gases. The heated air laden with water vapour is removed through suitable ventilators in the walls or roof of the chamber. Sometimes the heating element consists of a series of pipes placed round the walls, through which either hot water or steam is circulated. The air inlets are then placed in that portion of the wall behind the heating pipes and the outlets in the walls or roof, in such a position that the heated air must traverse the chamber.

To increase the accommodation in the chamber, the goods are often placed on trays which are supported on racks. These chambers usually work at atmospheric pressure, but where recovery of the vapour evolved is desirable, the outlet is connected with a suction fan. A development of the ordinary chamber drier is the vacuum shelf drier, manufactured by various firms such as F. Shaw, J. P. Devine Co. and G. Scott and Sons. This plant, illustrated in Fig. 3, consists of a heavily ribbed cast-iron box fitted with a number of shelves. These shelves are made of rolled steel plates flush-riveted together at the edges through a welded ring. Steam is admitted to the space between the plates through bent pipes which allow of the expansion or contraction of the shelf with variations of temperature. An inlet pipe is attached to one corner of each shelf, the other end of the pipe being connected to a steam header, which forms an integral part of the outer casing. The shelves are so arranged that the condensed steam will drain to another corner of the plate, from which it is removed by a second pipe, which

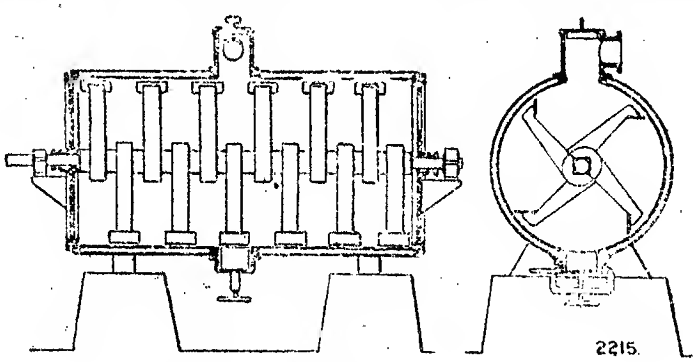
s connected to a second header, also forming part of the outer casing.

In the smaller sizes, only one door is provided, but for larger driers a door is fitted at each end if required. The doors may be of the hinged or sliding pattern, and when closed form an airtight joint by the pressure of their machined faces against



Drier by the Lennox Foundry Co., Ltd.
Fig. 5

a rubber ring contained in a groove cut on the inside skirting. Windows are fitted in the doors to permit of inspection of the material in the dryer during the drying operation. A cast-iron vapour pipe connects the top of the casing with a condenser. Each stove should be provided with its own con-

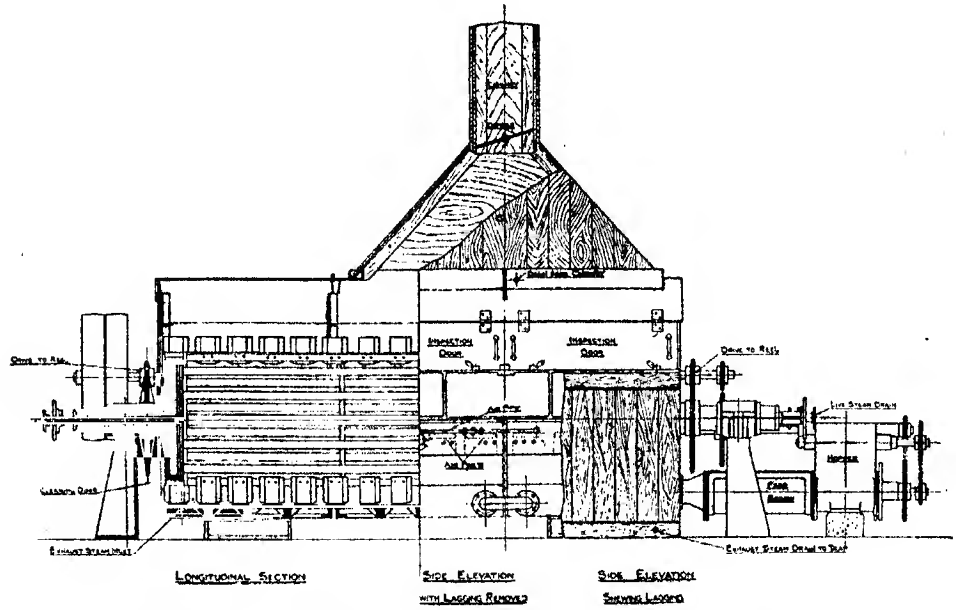


Firman Drier by Manlove, Alliott and Co., Ltd.
Fig. 6

denser, for, if a number of these stoves are coupled to a common condenser, it will be found that for efficient working all the stoves must be charged at one time. If an attempt is made to introduce a newly charged stove into the system, after drying has been in progress in the other stoves, it will be found that drying in these stoves is stopped, and remains so, until the contents of the newly charged stove become as dry as the others. Dryers of this type, whether of the cylindrical or box pattern, are designed to withstand vacuum, and are suitable for drying such substances as dyes, explosives, fine chemicals, foodstuffs, extracts, etc. This type of dryer is sometimes electrically heated. Another type of dryer, illustrated in Fig. 4, consists of a flat bottom cylindrical pan, provided with a steam jacket. The pan is provided with a cover, to which is attached the mechanism for operating the stirring and the stool for the vapour pipe. The charging hole is situated in the cover, whilst the machine is discharged through a rectangular opening in the bottom of the pan, which can be closed by a hinged and balanced door. This dryer is designed to obviate

the labour required in charging and discharging the shelf type of drier. Here the material is fed into the drier in bulk, and during drying is continually broken up and turned over by the stirring gear, which also automatically discharges it through the opening in the bottom of the pan. Sometimes the outlet for the pan is provided at the side (Fig 5). In the Firman drier, made by Manlove, Alliott and Co. (Fig 6.), a steam jacketed cylinder made of mild steel plates is mounted with its axis horizontal. Inside this cylinder and rotated by a suitably driven central shaft are a number of scrapers. The material is fed into the drier through an opening in one of the end plates of the machine, and discharged through a second opening at the lowest point of the cylindrical wall. The only difference between this machine and the Shetland drier is that the upper portion of the latter machine is rectangular instead of semi-circular in cross-section. These machines are largely used in the handling of waste products during their conversion into manures. All the above machines are of the discontinuous type, and, in addition to the labour often involved in charging and discharging, there is frequently a considerable heat loss due to the cooling down of the plant before discharging operations can begin.

(To be continued)



Imperial Grain Drying Machine by Blair, Campbell and McLean, Ltd.

Fig. 7

It is announced that Mr. H. Hollings, M.Sc., senior gas chemist to the South Metropolitan Gas Co., has been appointed chief gas chemist to the Gas Light and Coke Co.

THE USE OF GRAPHS IN CHEMISTRY

By J. R. JERROLD, M.A.

The use of graphs to show solubilities at varying temperatures is well-known, and other graphs showing the composition of binary and ternary alloys are of frequent occurrence but some other curves receive inadequate attention in our chemical publications.

The change in radioactive substances and all other changes where the rate is a uniform percentage of the value at a given moment are indicated by the curve $y=e^x$ shown below (Fig. 1), in which the horizontal distance x denotes the time, and O A represents the state at the time which is taken as the origin.

The curve $y=e^{-x^2}$ deserves far greater attention from chemists than it receives. It is shown in Fig. 2, and the theory of probabilities proves that it represents the curve of normal error. The line O A

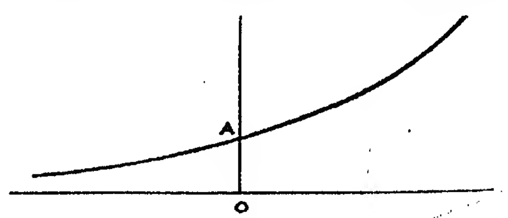


Fig. 1

which divides the curve symmetrically separates the departures due to chance errors into two classes, those which are too little, and those which are too great. The vertical distances show the number of

such errors; small errors are those close to the median line, they are frequent in number. The large errors which are shown by greater distances from the median line occur less frequently and the curve will, at a suitable distance, become practically coincident with the horizontal axis. This implies that errors exceeding a certain figure will practically not occur.

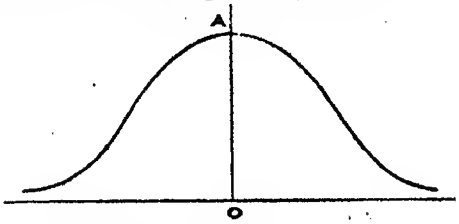

FIG. 2.

The importance of this curve in chemistry is obvious. If a score or so of determinations of an atomic weight be made and suitably plotted on the basis of this curve, the median line can be drawn and this denotes the probable true atomic weight. So, too, a number of inaccurate analyses of a compound will—if sufficiently numerous—enable us to determine correctly the true proportions. It is the only curve that enables the truth to be rigidly deduced from inaccurate premisses. In fact, what we mean by truth is simply the median line drawn through the curve which results from plotting human opinions, whether true or false. This is, of course, merely a mathematical statement in few words of Lord Balfour's "Foundations of Belief." If only we can get some definite statements of the beliefs of many individuals as to the theory of solution, the existence of bivalent hydrogen atoms, or any other problems where opinions are not unanimous, the truth can be elucidated by plotting.

But this curve shows not only the truth and the probability of error, but the normal and the probability of the abnormal. We may take the median line to show the average height of men, the very tall and the very short will be denoted by positions close to the horizontal line. Or we may arrange humanity in the order of their intelligence; the great mass of normal people occupying the central positions in the curve, Fellows of the Royal Society on the extreme left, lunatics on the extreme right. If the members of the Society of Chemical Industry be classified in this manner, one can judge how long it will take for them to secure their Chemical House. It depends on the average member.

The curve may be considered politically, the extreme right will be occupied by such men as Lord Curzon and Lord Birkenhead, the extreme left by some vigorous men from the Clyde school of politics. The most elementary integration will enable one to see what types of opinion must be included to enable a Prime Minister to command a majority. If a Prime Minister includes the extreme men, he will have to include a great length of horizontal space to obtain a majority; on the other hand, the central party requires only a short horizontal length in order to include a majority. This principle is capable of frequent application, and the mathematical analysis is not so difficult as might be expected.

FORTHCOMING EVENTS

Apr. 4. SOCIETY OF CHEMICAL INDUSTRY, *Liverpool Section*, The Clubrooms of the Overseas League, 14, Elliot Street, Liverpool, at 6 p.m. "Agriculture and Chemical Industry: Some Suggestions for Closer Co-operation Between the Chemical Manufacturer and the Farmer," by E. H. Rideout, B.Sc. An informal dinner will be held after the meeting at the University Club, Mount Pleasant.

Apr. 4. SOCIETY OF CHEMICAL INDUSTRY, *Birmingham Section*. Joint meeting with the Chemical Engineering Group, at the White Horse Hotel, Congrieve Street, Birmingham, at 6.30 p.m. "The Premier and Other Disintegrating Mills and their Applications in Industry," by Captain F. J. C. China. Informal supper at 8.30 p.m.

Apr. 4. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*. Annual general meeting, the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "The Tautomerism of Amidines," by Prof. F. L. Pyman, D.Sc., F.R.S.

Apr. 7. CERAMIC SOCIETY, Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. (1) "Note on the Use of Wood-Wool as a Packing Material," by B. Olsen. (2) "Electrical Porcelain; the Effect of Varying the Composition upon some of its Properties," by E. Watkin. Short communications will also be given by F. S. Worthington and Dr. J. W. Mellor.

Apr. 7. SOCIETY OF ENGINEERS, the Apartments of the Geological Society, Burlington House, Piccadilly, W. 1, at 5.30 p.m. "Gas-firing (Flame Control)," by A. C. Ionides.

Apr. 7. INSTITUTION OF THE RUBBER INDUSTRY, The Engineers' Club, Coventry Street, Piccadilly, W., at 8 p.m. (1) "Improvements in Education in the Rubber Industry," by Dr. T. J. Drakeley, and (2) "The Buyer Criticises the Manufacturer," by H. F. Trevillion.

Apr. 7. SOCIETY OF CHEMICAL INDUSTRY, *London Section*, at the Royal Institution, 21, Albemarle Street, W. 1. Prof. H. E. Armstrong, F.R.S., will give an address on "Sir James Dewar as an experimental inquirer," with demonstrations.

Apr. 8. INSTITUTION OF PETROLEUM TECHNOLOGISTS, The Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "The Crude Oils of Burmah and Assam," by W. J. Wilson, F.I.C.

Apr. 8. INSTITUTION OF CIVIL ENGINEERS. Joint meeting with the Institute of Chemistry and many other Engineering Societies, Great George Street, Westminster, S.W. 1, at 6 p.m. Discussion on "Standards of Comparison in Connection with the Thermal Efficiency of Internal Combustion Engines.

Apr. 8. INSTITUTE OF METALS, *North-East Coast Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. Annual general meeting. *Birmingham Section*, the Chamber of Commerce, New Street, Birmingham, at 7 p.m. Annual general meeting.

Apr. 10. INSTITUTE OF METALS, *London Section*, the Institute of Marine Engineers, at 8. "Failures in Metals and Alloys," by G. H. Gulliver, D.Sc.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

July 9—12

PATRON: H.M. THE KING

Preliminary information regarding this meeting was given on p. 309 of *Chemistry and Industry* for March 21.

A programme will be issued shortly.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

OFFICIAL NOTICES

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready, and copies are in course of being despatched to purchasers.

The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

For full particulars see page xiii. of the Advertisement Section of the issue of March 28.

BIRMINGHAM AND MIDLAND SECTION

During the meeting held on March 18, Mr. A. W. Knapp read a paper on "The Fermentation of Cacao," of which the abstract reached us too late for inclusion with the account of his paper on the theobromine content of cacao.

Mr. Knapp said the cacao bean, as it came from the pod, was covered with a fruity pulp. It was necessary to dry the bean in order to obtain a stable product, and the drying could be more rapidly accomplished if the beans were first allowed to ferment, either in boxes or heaps. *Saccharomyces cerevisiæ*, *S. ellipsoideus* and *S. theobromæ*, had all been found in satisfactory cacao fermentations. With "forastero" cacao, which was fermented for six or more days, after the third day the temperature is usually 48–50° C. This was a very high temperature for yeast fermentation and was not satisfactorily accounted for by the presence of acetic bacteria. The cider-like liquid which ran away during fermentation was known as "sweatings," and about 10 million gallons of this liquid, which contains about 10 per cent. of sugars, ran to waste every year.

A detailed account was given of the changes occurring in the interior of the bean during fermentation. These included the distribution of the isolated masses of violet pigment throughout the bean, and the oxidation of the tannins to brown bodies in the presence of an oxidase. It was this oxidised tannin which produces the chocolate colour of roasted cacao beans. It was, however, odourless and tasteless. Oxidation thus was responsible for a reduction in the astringency but did not account for the characteristic cocoa aroma. The oxidation was continued during drying.

Fickendey had suggested that the fermentation of cacao might be replaced by killing the bean by freezing, and removing the pulp by washing. Perrot had suggested that the bean should be steamed, and the pulp removed by dilute alkali. Neither of these methods gave a bean which had the chocolate aroma on roasting. Experiments were described to show how far the normal changes could be brought about in the absence of the pulp. In the presence of 2 per cent. acetic acid at 40–43° C. the skinned beans assumed the appearance of fermented cacao, but, on roasting, the aroma was lacking. Research was needed to show what substances were produced in the bean during fermentation, which, on being heated, gave the cocoa aroma.

GLASGOW SECTION

The seventh meeting was held in the Institute of Shipbuilders and Engineers, on March 28, and was presided over by Mr. W. E. Moodie, F.I.C., Chairman of the Section.

Prof. T. S. Patterson gave an addendum to a paper on "Modifications of Laboratory Apparatus," communicated by him to the Section at its last meeting, and he was able to show an improvement on the second of the series then exhibited which had since occurred to him: *namely*, by the suitable change and simple redesign of the receiver for distillation under reduced pressure applicable to small quantities of distillate. He showed how this applied to larger quantities and also demonstrated another piece of apparatus designed for this purpose a long time previously, but suffering from the disadvantage of too large a number of joints which had to be kept air-tight. A description of a test-tube rack of simple construction, which rapidly drained the tubes concluded Prof. Patterson's remarks.

Dr. J. A. Cranston then read a paper on "The Influence on Chemistry of the Recent Knowledge gained of Atomic Structure," beginning with a review of the genetic relationship of the elements, in which he pointed out the undue prominence given to the number 8 by the classification suggested by Newlands and incorporated by Mendeleeff in his table, which, notwithstanding its failings, had been to chemists a map of the world. One thing, however, remained clear, and that was that some relationship obviously existed between the elements, as shown in the diverse forms in which they had been tabulated, but that the rare earths had generally been a difficulty. A table constructed on the Rydberg series and atomic numbers was shown and made the basis of further remarks. A consideration of Sir J. J. Thomson's work showed that some relationship existed between matter and electricity, and this relation had been resolved into that between the electrical content and the chemical properties and structure of the atom by the discovery of radio-activity, for the expulsion of α- and β-particles was followed by the well-known change in position in the classification—or change in the atomic number—to that of the resultant element. That the relationship between matter and electricity was not confined to the radi-

active elements was soon shown by Sir Ernest Rutherford, who, by bombarding matter with α-particles, made the application general throughout the table. That only 1 in 10,000 α-particles were deflected in their passage through matter was an object of wonder, and led to the conception of the condensed positively charged nucleus. This was greatly added to by Moseley's famous set of experiments, from which the idea of atomic number arose. The discovery of isotopes by Aston was a matter of great significance, for inasmuch as the atomic number for any element was constant and indicated the net charge on the nucleus, it must be possible for the element, though the net change indicated it was homogeneous in chemical properties, to be composed of atoms differing in mass, and hence in the arrangements of their nuclei. To the simplest type of nucleus having one positive charge, such as was found in hydrogen, the name "proton" had been given, and all elements might be considered to be composed of various groupings of protons and electrons.

Dr. Cranston then dealt with various suggestions as to structure based on the chemical properties, and elaborated in further detail that of Lewis and Langmuir, whose postulates were three in number: (1) The electrons round any nucleus tend to arrange themselves in a stable form, namely, that of the octet in the lighter elements. This stable form is seen in the rare gases, the zones or shells of which successively contain 2, 8, 8, 18, 18, 32, electrons. (2) The electrovalency of an element is governed by the number of electrons which it either lacks or has in excess of this stable number, and which it will collect or part with to attain it. Sodium, of atomic number 11, will part with one electron to fluorine, of atomic number 9. Each will then have 2+8, and be held together by electric attraction. Mg and O, atomic numbers 12 and 8, will interchange 2 electrons. Identically arranged molecules are given, differing only in electric attraction, shown to a great extent in the different physical properties of MgO to NaF. This is equivalent to the "inorganic bond." Crystallographically these two would be expected to be isomorphous, which was what Bragg's X-ray examination had shown. (3) Covalency may also be shown by an element, governed by its power of sharing electrons, as in the gases O_2, N_2, F_2, etc., and compounds of two or more elements as in the charged ion SO_3'', SO_4'', etc. This was a much stronger bond than that of electrovalency and was equivalent to the common "bond" of organic chemistry. Any dissociation leads to a breakdown of the compound, whereas in electrovalently-joined compounds dissociation readily leads to ionisation—a reversible change. Ions, however, are never found to have large charges, and hence a limit to the exchange of electrons is patent, controlled by Coulomb's law. A sort of compromise therefore exists in such a case as iron, which sometimes is found as $Fe^{\cdot\cdot}$, sometimes a $Fe^{\cdot\cdot\cdot}$. No explanation of the complexity of intermetallic compounds had so far been given, but the results of Prof. Edwards were of great interest. Mg_2Pb, Cu_2Sb, Cu_3Sb had been obtained by him, the first and last being of salt-like character and zero electroconductivity, whilst Cu_2Sb showed the ordinary conducting properties of alloys. All were of Langmuir's "complete compound" type, in which each component formed a complete stable octet. Dr. Cranston touched also on subsidiary points of valency, other than the rare gases, in the table and the cases of complex salts, but time prevented elaboration.

After the discussion, during which a number of interesting points were dealt with, Dr. Cranston was most cordially thanked for his paper.

NOTTINGHAM SECTION

At the meeting on March 26 a paper entitled, "Some Scientific Aspects of Puering and Bating," by C. E. Pickard, was read by Mr. D. J. Law, B.Sc.

An account was given of the methods of research into the chemistry of puering and bating, and a comparison was made of the results obtained by recent investigators.

In the discussion Mr. Burford asked how many bating enzymes had been isolated, and what was the action of the enzymes on collagen? Mr. Powell enquired whether pepsin could be utilised during the process? Mr. Pentecost asked if acetic acid acted upon the skin to produce shrinking or unevenness? Dr. Prideaux enquired if pancreol was not more expensive to use than old-fashioned bating materials? Mr. Barber wished to know if pure cultures of the various enzymes used in bating had been isolated?

In reply Mr. Law stated that at least five of the enzymes present in the puer liquor had been isolated. Usually trypsin will not act upon collagen, but with excess liming, the collagen becomes partially hydrolysed, and is then acted upon like gelatin. Pepsin could not be used, as it will only work in an acid medium, whereas puering was always carried out in an alkaline bath. The action of excess of acetic acid on the skin would produce swelling, but in practice only sufficient was used to neutralise the lime. The use of enzymes in bating was certainly more expensive, but gave much better conditions of working. Several enzymes used in bating have been isolated.

Mr. Powell then read "The posthumous papers of J. M. Wilkie, B.Sc., F.I.C., in collaboration with his colleagues," collected by Mr. H. Droop Richmond, F.I.C.

The estimation of morphine by using a plugged separating funnel instead of the British Pharmacopœia method of tared filter papers was first described. Details were then given of an extraction method for estimating morphine when the ordinary crystallisation method was inapplicable, and the use of Denigé's colour reaction to the quantitative colorimetric estimation of morphine was described as a satisfactory method for low limits of morphine. The use of powdered silica and tribasic calcium phosphate was suggested to aid the ignition of difficult substances, by increasing the surface exposed to air, and protecting the material of the crucible. A note on soluble filtering media described the use of camphor as a filtering medium for use in bismuth determinations.

During the discussion, Mr. Burford said he rather doubted the colorimetric estimation of small amounts of morphine, and considered that a blank parallel estimation should be performed. The addition of powdered silica to give an increased air space seemed a good idea, as calcium phosphate would appear to be a non-conductor of heat. The camphor filter also would seem to be very useful.

Mr. Powell, in reply, stated that a blank control experiment in the colorimetric method was necessary, although this method was only used where morphine was well below the minimum of the Dangerous Drugs Act.

EDINBURGH AND EAST OF SCOTLAND SECTION

The annual general meeting was held in the Hall of the Pharmaceutical Society, Edinburgh, on March 18, 1924, Dr. Alexander Lauder in the chair.

Dr. Alexander Lauder was re-elected chairman for the ensuing year, and Mr. W. A. Williams was elected vice-chairman. Mr. W. T. H. Williamson was re-elected hon. secretary and treasurer, and Dr. T. Rettie, hon. auditor. The following new members of Committee were elected: Prof. Sir James Walker, Prof. Hendrick, Dr. H. E. Watt, and Major R. Bruce.

The sixth ordinary meeting took place after the business meeting, when a lecture was delivered by Dr. N. V. Sidgwick, M.A., F.R.S., on "Co-ordination and Co-valency."

Chemical combination is due to rearrangement of the outer or valency electrons between the atoms concerned. This can occur in two ways, leading to two kinds of linkage:—

(*a*) One or more electrons are transferred from one atom to the other, the atoms being held together by the resulting electrostatic charges (electro-valency, ionisable, not directed in space).

(*b*) One or more pairs of electrons (one pair to each link) are in some way shared between the atoms so as to count for both (covalency, non-ionisable, directed).

No other form of valency need be assumed if we remember (1) that besides the 'octet' (corresponding to a covalency of 4) we may have a stable group of 12 or even 16 shared electrons (covalency of 6 or 8), as in SF_6 and OsF_8; (2) that though the two electrons required for a covalent link usually come one from each atom, they may both be provided by one of the atoms. This leads to a second kind of covalency, which we may call a co-ordinate link. Such links attach the NH_3 groups in a complex ammine.

Hence the ordinary covalency of an atom (like its electrovalency) is determined by the number of its valency electrons, *i.e.*, by its group in the periodic table. But in its co-ordinate compounds this restriction no longer holds, since there the other atom provides the electrons for the link. The covalency is, however, found to be limited in a different way by the position in the periodic table. The maximum covalency (co-ordinate or other) is for hydrogen 2; for the elements from lithium to fluorine 4; for those from sodium to about copper 6; and for the heavier elements 8. The reason for this limitation is not known, although it has a close relation to the size of the sub-groups of electrons on Bohr's theory.

An interesting discussion followed, the speakers including Prof. R. N. Craven, Prof. Wilson and Dr. J. A. Cranston, of the Glasgow Section, Prof. C. G. Darwin, Edinburgh University, and Principal Laurie, Heriot Watt College, Edinburgh.

CHEMICAL SOCIETY

The annual general meeting was held on Thursday, March 27, at 4 p.m., the President, Prof. W. P. Wynne, occupying the Chair.

The Treasurer, Prof. J. F. Thorpe, having presented the Report of the Council and the Balance Sheet, their adoption was moved by Dr. F. L. Pyman and seconded by Dr. O. L. Brady, both of whom referred with regret to the retirement of the senior Secretary, Prof. J. C. Philip, and the Editor, Mr. A. J. Greenaway. Prof. H. E. Armstrong associated himself with this expression of regret, and referred in congratulatory terms to the Council's efforts to co-operate with other Societies, particularly in the domain of publications. The Report and Balance Sheet were then duly adopted, and a vote of thanks to the Auditors was acknowledged by Dr. R. C. Farmer.

In acknowledging a vote of thanks to the Treasurer, Secretaries, Foreign Secretary and Council, Prof. Philip referred to the retirement of Sir William Tilden and Dr. Alexander Scott from the office of Vice-President, recalling that the former was responsible for the initiation of the Society's Annual Reports on the Progress of Chemistry, whilst the latter, who was President during two difficult years of the war, instituted the movement which led to the formation of the Association of British Chemical Manufacturers. He expressed his cordial thanks for the help afforded him by the Officers and Members of the Council with whom he had been associated during his eleven years' tenure of office, and to the Assistant Secretary; he also took that opportunity of emphasising the debt which Fellows owed to one particular committee, the Publication Committee, whose duties at the present time were especially arduous and delicate.

Sir William Tilden recalled the early days of the Society, of which he was elected a Fellow in 1864. In alluding to the then prevailing views of chemical constitution and interaction, he spoke of the differing character and number of the papers then and now read before the Society. He desired to congratulate the President and the Society on the progress it had made, and to wish it every success in the future.

Dr. J. F. Spencer, Prof. A. J. Allmand and Prof. J. S. Brame were elected Auditors.

The President then handed to Prof. F. G. Donnan the Longstaff Medal, saying that by his researches and inspiration he had established an unrivalled position in British physical chemistry, and referring in the briefest terms to the scope of his work on colloid systems, on the application of thermodynamical principles to chemical problems, and in the domain of ionic chemistry. Prof. Donnan expressed his appreciation of the honour thus conferred upon him.

In his Address, the President took for his theme the debt which chemistry owes to Russia, referring

first to the efforts in which the Society had joined to mitigate the acute distress existing among Russian chemists, and expressing confidence that the high tradition of their science would be maintained as time and circumstances would permit. It was largely to the fact that, except in the earlier years, the Russian language was usually employed, that he attributed some lack of appreciation in this country of so distinctive a school of research.

With a brief reference to the conditions under which chemical study and research have been carried out in the past, and to Lomonosoff's anticipation of Lavoisier's experiments on the calcination of tin and lead in air, Prof. Wynne turned to Kazan as being (apart from Petrograd, the home of Mendeléeff, Menschutkin and Beilstein) the most interesting centre of chemical learning, having an influence on the development of Russian chemistry comparable with that of the famous laboratory at Giessen. Claus, the first occupant of the Chair of Chemistry at Kazan, was best remembered for his discovery of ruthenium; Zinin, who became Professor in 1837, originated the use of ammonium sulphide in the reduction of nitrobenzene, nitronaphthalene and *m*-dinitrobenzene to the corresponding amino-compounds. His successor, Butleroff, established a school of thought which quickly became prominent, and further enhanced his reputation by the publication in 1864 of a text-book of organic chemistry which was remarkable even in a remarkable age. Butleroff, on going to Petrograd, was succeeded by Markownikoff, who was in turn followed by Saytzeff and Flawitzky. Names such as these naturally led to a brief survey of the development of the Russian Chemical Society, which was founded on 6/18 November, 1868.

The debt which chemistry owes to the Kazan school could be broadly stated to be the searching scrutiny of the property of unsaturation as manifested, on the one hand by hydrocarbons isologous with the paraffins, and on the other by carbonyl derivatives. Butleroff's work on the interaction of methylene iodide with silver acetate, and the action on the product of lime water, had laid some of the foundations of Bayer's view that the photosynthesis of sugar from carbon dioxide and water is achieved through the intermediary of hydrated formaldehyde; the part which he took in the controversies concerning molecular constitution, and particularly the constitution of isomerides (including his synthesis of *tert.*-butyl alcohol in 1864) were a not unnatural result of his association with Wurtz and Kekulé. Further, a claim might reasonably be made that the prolonged use of the zinc alkyl compounds as synthetical reagents until the discovery of the more convenient magnesium compounds was due mainly to the use made of them at Kazan by Butleroff (*e.g.*, in connexion with pinacolin), and later by Saytzeff, Wagner, and their collaborators. Polymerisation also engaged Butleroff's attention, and to him the current explanation of the course of the reaction among olefines was due.

One of Butleroff's first students at Kazan was his successor, Markownikoff, who put forward certain rules relative to the behaviour of directive influences, and the formation of additive compounds which, although not rigid, were useful, and have led by stages to modern views of partial valencies, residual affinities, and induced alternate polarities. Later he turned his attention almost exclusively to an investigation of the naphthenes, which he discovered in Caucasian oil, the change in structure which may occur when cyclic compounds are reduced by hydrogen iodide being incidentally discovered.

Much of the work of Saytzeff was concerned with the systematic synthesis of alcohols by the aid of zinc alkyl compounds; in this enquiry he was assisted by his most brilliant student, Wagner, who afterwards continued the investigations at Petrograd. By carefully-regulated reactions, Wagner was able to show that the first stage in the oxidation of an unsaturated carbon chain was the formation of dihydroxy-derivatives, with subsequent disruption at that point or elsewhere; his results led to an acceptable view of the course of the action of fused potassium hydroxide on oleic acid, and contributed towards the more recent elucidation of the probable manner in which fatty acids are broken down by the organism. Wagner's studies in the terpene series were no less noteworthy.

Prof. Wynne then spoke more particularly of the chemistry of the carbonyl group, in the earlier development of which Butleroff, Saytzeff and Wagner were all concerned, and mentioned the work of Petrieff, of Odessa, on mesoxalic acid. He also briefly referred to the once vigorous condition of the schools of chemistry in the former Russian cities of Warsaw, Riga, and Helsingfors, associated with the names of Walden, Aschan and Komppa, and recalled von Lebedeff's researches on alcoholic fermentation.

Having emphasised the advantages which would accrue to chemists from a more widespread study of the Russian language, the President concluded by saying that, with sympathy and admiration for those who are carrying on the good work, he looked forward to the time when their nation would again play a part in the advancement of chemistry no less vigorous and distinguished than was the case before the war.

Prof. H. E. Armstrong moved a vote of thanks to the President, and accompanied his proposal with a request that he would allow the Address to be printed. Seconded by Prof. H. B. Baker, the vote was carried with acclamation.

The President then declared the following to be duly elected, a ballot not having been necessary:—Secretary, C. S. Gibson; Vice-Presidents who have filled the office of President, Sir J. J. Dobbie, W. H. Perkin; Vice-Presidents who have not filled the office of President, A. J. Greenaway, J. C. Philip; Members of Council (Town) O. L. Brady, A. E. Dunstan, T. S. Moore, (Country) D. R. Boyd, B. Lambert, F. L. Pyman.

The Informal Dinner was held at the Hotel Cecil after the Annual Meeting, and some 260 Fellows and their guests were present.

Mr. H. J. Evans proposed "The Chemical Society," coupled with the name of the President.

The President, in reply, said this was the first occasion on which there had been an informal dinner,

and as it was an obvious success, he was sure the Council would endeavour to make it an annual affair.

Prof. G. T. Morgan, F.R.S., proposed "The Retiring Secretary," coupling with the toast the name of Prof. J. C. Philip, F.R.S. The speech was mainly in a humorous vein, but in referring to the valuable work which Prof. Philip has done since he became secretary, Prof. Morgan said the war came within 18 months of Prof. Philip's assumption of the office, and that fact alone increased the secretarial duties enormously, not to mention the increased membership. One outstanding fact during Prof. Philip's tenure of office was the admission of women as Fellows of the Society. This innovation, hinted Prof. Morgan, might have been the cause of the disappearance of Prof. Philip's facial adornment. Another step forward to be associated with Prof. Philip was the co-operation of the Society of Chemical Industry with the Chemical Society in the publication of chemical abstracts. That had led to the formation of the Bureau of Chemical Abstracts, a composite body representing both Societies, and of which Dr. Philip is the first Chairman. After an amusing reference to the attributes of the ideal secretary, Prof. Morgan said that Prof. Philip had all the qualities which an ideal secretary should have as well as other excellent personal qualities, all of which made it a matter of regret that he was resigning his office. They were all extremely grateful for the work he had done for the Society as senior executive officer, and hoped that they would continue to have the benefit of his mature advice.

Prof. Philip, in replying, said it would be idle to deny that the machinery of the Society was now a little more up-to-date than it was, say, 10 years ago, and he consoled himself with the reflection that the time and energy which had been put into that work had not been wasted. It was fortunate that the Chemical Society should have taken a foremost part in endeavouring to bring about the co-ordination and co-operation of the different chemical bodies. It had also assisted in bringing the Association of British Chemical Manufacturers into existence, and there was the joint Library scheme, whilst last year the separation of the Transactions from the Abstracts had rendered it possible for there to be one independent British organisation for the production of abstracts, and this might possibly ultimately lead to a sole publication in the English language. This was work accomplished of which the Society might feel proud. Finally, Prof. Philip congratulated the Council on arranging this informal dinner, because it enabled them to escape the sort of exhibition there had been at one or two recent dinners when very distinguished persons had displayed a colossal ignorance of what the chemist really was. Referring to Prof. Morgan's remark about his changed appearance, Prof. Philip said that his students had defined this as a "beavercavement."

The final toast was "The Longstaff Medallist for 1924," coupled with the name of Prof. F. G. Donnan, F.R.S. In proposing this toast, Prof. E. C. Baly, F.R.S., said that in Prof. Donnan they had a personality which had both dominated a very far-reaching school of research, and had also endeared him to all. In trying to voice appreciation of Prof. Donnan he found himself overwhelmed by the recognition of his own indebtedness to him, but he was proud to speak of Donnan as a stimulating personality, as a great philosopher, of his never failing wealth of helpful criticism and advice, and of his enthusiasm for Dame Nature and her hard work. The Longstaff medal was a triennial epoch in the annals of the Society, and he felt that the Council, in honouring Prof. Donnan, had honoured itself by inscribing a very distinguished name on an already distinguished roll.

Prof. Donnan, who was enthusiastically received, said he failed to recognise the picture which Prof. Baly had painted, but he again thanked the Council very heartily for awarding him the Longstaff medal, and the company for the manner in which the toast had been received.

There was a musical programme during the evening, part of which was contributed by members of the Society.

INSTITUTE OF CHEMISTRY

Mr. Marlow, Assistant Secretary of the Institute, speaking before the Edinburgh Section on March 20, the Glasgow Section on March 21, and the Birmingham Section on March 24, said that, although his remarks must not be taken as being an official expression of the views of the Institute, the consolidation of British chemical interests was one of such immediate importance that there were certain principles which should be discussed by the Local Sections.

The main objects of co-operation were :—

(a) *Economy in Organisation.*—As an instance, they would perhaps realise that the indiscriminate circularisation which was now going on from all the bodies was extraordinarily wasteful in labour, in materials, and in postage. Given co-operation it was a simple matter to send all this forth in an orderly economical manner.

(b) *Economy in Publications and in Printing.*—Much had already been done in this respect by the provision of a Bureau of Chemical Abstracts, but much remained to be done in other directions, and he hoped that in time we should see one Journal covering every aspect of British chemistry. This would, by reason of its large circulation, prove a still more valuable advertising medium, and reduce thereby the cost of publication. They, as Members of the Institute, could give a lead. Their own Journal was only issued every two months and, consequently, much of what it contained was already very much out of date. Reports of the sectional meetings would have appeared in *Chemistry & Industry* and in the trade papers, so that the Institute's Journal was not only out of date, but to an extent provided an unnecessary duplication. It cost £650 last year for printing and postage alone—the Institute had a good opportunity of giving a lead in this matter.

(c) *Provision of a Joint Library.*—Much had already been done in this direction, and chemists as a whole should be very grateful to the Chemical Society, who had allowed their Library to form the nucleus of a really national chemical library.

(d) *Subscription*.—All of these suggestions must nevitably lead either to an economy to the individual members in their subscriptions or to the provision or members of a great deal more for the subscriptions hey paid—or both. It was impossible to suggest what savings might be expected until one knew he whole position of each Society, but it was perfectly clear that some economies must be effected. There would be a possibility of a composite subscription, and some individuals might find that they were involved in a higher subscription. About 1800 members of the Institute belonged to no other chemical society. He was not so much concerned at the fact that the other important societies included nearly 6000 members who belonged to no other society, because these societies included people who did not consider themselves qualified chemists, but every member of the Institute was a qualified professional man; it was deplorable that so many were content to lose the opportunity of maintaining their professional equipment which was provided by membership of the scientific societies. If a composite subscription were introduced, there would clearly be an increase in subscription for such members. As to the financial mechanism, it was impossible to make very definite suggestions, but there would be a possibility of considerable economy in entrance fees, which would induce younger members to join since the main object of an entrance fee was to enable the societies to build up a capital reserve, and, if all the societies were to work together, they would have a considerable joint-capital reserve. A man at present belonging to the three main societies should get all the advantages at about two-thirds of the present cost.

Two factors were essential if they were to secure this co-operation, namely, a central organisation and common headquarters.

With regard to a central organisation, they would be wise to make the fullest use of all existing material. There already existed a Federal Council for Pure and Applied Chemistry, and if this body were given definite powers, and were really representative of all chemists, it constituted the obvious nucleus of the governing body. He conceived a Commonwealth of Chemistry in which the Federal Council or, to avoid confusion of metaphors, the newly constituted General Chemical Council, formed therefrom, would be assigned definite functions (with power over certain monies), and the separate societies would all continue to perform the useful services for which they were created, save only that the General Council would do that work which affected them all. Members of the Institute would realise that the formation of a Council superior to their own would act rather to strengthen than to weaken their professional status. If, for example, the Council contained the Councils of all three of the larger Societies, its only objection was that it would be too unwieldy. Ninety-five per cent. of the members would be found to be Fellows of the Institute, and all would be staunch supporters of the Institute's ideals.

He preferred not to discuss the question of a chemical headquarters in any detail, but he would ask those present to bear certain fundamental principles in mind.

The main object of the plan was to provide a headquarters for all the chemical organisations, including adequate meeting halls and library facilities. For convenience, and in deference to the dignity of chemistry, they should have a meeting hall at headquarters, instead of seeking the hospitality of engineers, and it was most wasteful to set up a separate library away from headquarters.

The whole problem hinged upon the question of finance. An ambitious scheme had been propounded in 1918, but nothing definite had come of it. They would agree that chemists were not prepared to pay £25 a head, and that was the amount which would be involved if their expenditure were of the order of £300,000, as had been suggested. They must, therefore, seek some other solution. The experience of the Institute in building its own headquarters only nine years ago had shown it was very unwise to put up a new building with a reasonably estimated margin for expansion. In much less than nine years the Institute building had proved quite inadequate for the purposes for which it was built, and those who planned Chemistry House as a self-contained building would have to be very long-sighted if they were to plan an adequate building. He doubted whether any man could foresee what would be the needs of chemistry in fifty years' time, or what space would be necessary for a chemical library in fifty years' time, the science was growing so rapidly.

It was very desirable that all the functions of chemical bodies should be exercised in the one building. At the present moment, the chemical bodies were spaced unevenly all over London. This lack of centralisation affected not only Londoners, but more particularly country members, who had to spend a deal of their limited time in travelling about London.

Their premises must be available to the chemical organisations at as low a rental as possible. They must remember that the Chemical Society was now living rent free, and that the Institute was, in effect, living rent free, since it had its own premises. They would be able to avoid the waste of capital so noticeable when each of the Societies had its separate Council Room and committee rooms, which remained idle except for a very few hours each week. Chemists must try to think of these matters in terms of rental. The Institute's Council Room and Library occupied about 1700 sq. ft., and if they had to rent that space they would have to pay well over £1000 for the rent of those two rooms. It was being used very extravagantly at present.

The final point was that, if they were to transfer the Chemical Industry Club to their headquarters, they would lose the great advantage which was provided at Whitehall Court, where there was a public restaurant, which formed the nucleus of the catering service. Consequently, if they wished to remove the Club, they must think of the possibility of having such a restaurant available.

This matter had recently become of considerable moment, since the Society of Chemical Industry had received as a legacy a very useful nucleus for the funds required for headquarters, either for the Society—

or for chemistry as a whole. Many schemes might be put forward but he hoped that they would think in terms sufficiently large to bring all the functions of chemistry into the one building. This would cost money, and he doubted whether that money was available on the purely voluntary basis. Therefore, he suggested that Chemistry House should be run as a business proposition; that they should float a separate company, in which the main bulk of the shareholders were chemists, in order to secure a building which was very much too large for their immediate needs and that they should let for profit the space not immediately required. He thought of a scheme which would require roughly £300,000 in capital. He hoped that the chemical societies would invest some of their capital funds in a mortgage on the property. The space actually required for the chemical bodies, including a library of the size suggested to him by the Librarian of the Chemical Society, would be nearly 20,000 sq. ft.

The professional standing of chemists in the eyes of the world depended upon the public esteem of their work, and they must neglect no adventitious aid to publicity. They should use the importance of their headquarters as a piece of propaganda by assuring that their building had a frontage on to an important thoroughfare in London. This would, however, involve a rental equivalent to nearly £9000 per annum. They would, therefore, agree that the extent of the accommodation required even now by chemistry was such that a plan conceived on a small or voluntary scale would be likely to fail.

This standing rental of £9000 represented a subscription of about 15s. per head for every individual in the chemical bodies. They should, therefore, utilise the profits from their letting—(*a*) to produce a reasonable, though perhaps small, return on the capital; (*b*) to allow the chemical organisations to live rent free; and (*c*) to devote the residue either to further interest on the capital, or to reserve. They would, however, realise that with (*b*) fixed at £9000, if the scheme were not conceived on a broad plan, (*c*) would varnish and (*a*) would be reduced to negligible quantities. On the scale he had suggested it was possible to make the scheme succeed, but he doubted whether the scale could be reduced. It had been suggested that they should not combine business and sentiment by allowing the chemical societies to live rent free, but they must remember the extent to which they were now rent free, and must realise that whether they would or not, they were considering a matter which represented one of the ideals of chemists. It did not seem to him to matter very much to their pockets whether that £9000 were used in providing an additional 3 per cent. interest on the capital, or in reducing subscriptions to the chemical bodies by the amount of about 15s.

He trusted that the Chemical Industry Club would move to headquarters as one of their first tenants, and he was assured that it was possible to secure a site which would interest some large restaurateur to take a large amount of space for a public restaurant, thereby securing not only the catering department of the club and a convenience for chemists, but a permanent advertisement of chemistry's headquarters. He hoped that the rest of the space availabl for letting would be taken up very largely by chemica manufacturers or merchants, or by others intereste in the advancement of chemistry, so that Chemistr House would be a real chemical headquarters t which the world-wide interests in British chemistr would naturally gravitate.

It had been stated that the Institute's function differed so materially from those of the other bodie that it should not enter into a scheme of co-ordinatio. Further, it had been urged that the Institute possesse its own headquarters, which were stated to b adequate.

On the first point, it should be stated that, apar from pure circularisation, the Institute's organisatio was necessarily more complex and more complet than that of any of the societies, and for this reaso was the more easily adaptable to dovetail the simila activities of the other bodies in the general interests o economies for chemists. For this reason, and because the common housing of all the bodies woul tend to their *rapprochement*, he held that the Institut should *not* hold aloof, but should throw in its weight If the Institute held back, and chemists spoke stil with two voices, none could say whether the Institute or all the other bodies speaking as a federation, was correct. At great inconvenience the office accommodation of the Institute had been made sufficient fo immediate needs, and for slight expansion. It could not be further extended without utilising space intended and specially suitable for other purposes If the Institute moved its headquarters to Chemistry House, the present building could be utilised as a research building, a purpose for which a quarter of the useful floor space was already used, thus securing a valuable additional asset.

Discussion at Edinburgh Section

Mr. Adam Watson felt that many of them would hardly ever see Chemistry House and that, therefore, the project might not appeal to the provincial members. They would be interested to know to what extent it would be possible to arrange for composite subscriptions and whether the scheme for federation would be able to conceive not only one British journal of chemistry but an international Journal of chemistry which would avoid duplication. One of the great difficulties of the Local Sections was the lack of interest shown by their members. Dr. Dobbin felt that the financial aspect was likely to prove the greatest bar to the realisation of such a scheme. Moreover, in many provincial centres they wanted to form their own chemical clubs. He would welcome economy in publications but had Mr. Marlow considered the position of the trade press? Mr. Bruce welcomed the scheme from the point of view of the advancement of science. To too many members the Institute was considered merely as a qualifying body. Mr. Williamson said that in Edinburgh they were keen on local co-operation and their only regret was that London had held the first public meeting on the subject. The scheme was most attractive, but he was intrigued to know what would be the financial position of the company when the chemical organisations wanted all the space available in

Chemistry House. Mr. Martin asked how the proposals had been received by the other main societies interested. It was perfectly clear that such a scheme of co-operation would eliminate wasteful overlapping.

Mr. Williamson interposed to say he knew that the question of accommodation of the Society of Chemical Industry was really pressing, and that the matter had already been discussed. He agreed that co-operation would reduce labour. The Chairman, Dr. Lauder, thought that the main difficulty was that so many members lived in the provinces, and since they could not get to town they would have to be persuaded of the real value to themselves and to the profession of the scheme. He could understand that it might appeal more readily to the members in the South of England. There was no doubt, however, that co-operation in the Journal and on Section meetings was valuable.

In reply, Mr. Marlow said that the advantages of a common headquarters applied just as much to provincial members as to London members. The main point they must bear in mind was the fact that the scheme would be putting the finishing touches to the quiet but effective work of fifty years of Councils of the Institute on behalf of the profession, and they must remember that it would bring their profession more prominently before the eyes of the general public by whom, in the long run, their professional status was decided. He quite realised that it would not be easy to secure the funds, but he was not pessimistic. He would like to see the consolidated organisations fathering future projects for the housing of their Sections, but they must first see that chemists as a whole were housed adequately in the interests of the whole profession, and not give primary consideration to the interests of any one Local Section. The plan was conceived upon such a scale that not even the most optimistic chemist would anticipate that all the space would be needed for chemistry. The need of accommodation was perhaps more pressing in the case of the Chemical Society.

Discussion at Glasgow Section

Dr. Rintoul, the Chairman, thought that it was desirable that chemistry as a science should function as one unit. He welcomed the proposal that there should be one entity subdivided into the different departments. He hoped that the proposals would also have the effect of eliminating the need for the formation of further bodies. He realised, however, that the financial aspect was of vital importance and by no means easy.

Mr. McCallum asked whether Mr. Marlow favoured the proposals put forward at the Liverpool Conference for the federation of scientific societies, to which Mr. Marlow replied that in his opinion the whole chain of those proposals could not be brought to fruition until the important link of chemical consolidation had been securely forged.

The meeting unanimously passed a resolution supporting the resolution of the London Section asking the Council to take steps to ensure co-operation, and, on the motion of Mr. McCallum, the Section unanimously adopted a resolution that the Local Section of the Society of Chemical Industry be invited to discuss the London resolution and to support it.

Discussion at Birmingham Section

Prof. G. T. Morgan, F.R.S., the Chairman, having expressed sympathy with the project called upon Mr. Johnson, who discussed the position of the British Association of Chemists in connexion with co-operation. Mr. Silvester said that there had been much vague talk of these projects, and they were glad to have some conception of the difficulties which were to be faced and of the principles upon which they could be faced. The proposals were ambitious but not incapable of realisation.

Mr. Marlow, in reply, said that he believed that the Association had been formed in the first instance through an under-estimate of the powers of the Institute to safeguard the interests of chemists. Their Charter expressly said that one of the reasons for the formation of the Institute was the desire to advance the attainments, character, and status of chemists. He hoped, therefore, that when all chemists were working towards one end there would be no question of any differentiation between the Institute and any other body dealing with one of the functions allocated to the Institute under its Charter. Where they might at present differ was as to the method of accomplishment of that aim, but he hoped that the two bodies would consult together on the lines suggested at Liverpool.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The Fuel Group met on March 12, under the presidency of Monsieur R. Etienne, to hear a paper by Monsieur J. A. Hardel on the possibility of industrial treatment of the bituminous shales of Madagascar. Monsieur Hardel first discussed the subject from the geological point of view, and gave some facts showing the industrial possibilities of the deposits, certain of them being large enough to permit of exploitation for hundreds of years. At present means of transit are very rudimentary, and both roads and railways will have to be established. Navigation on the local rivers would not be possible. The best way, therefore, would be to establish roads and pipe lines. Labour, food and fire-wood are abundant and would cause no difficulty. It would be advisable to work the deposits by shafts and to refine the material on the coast. The crude oil produced is similar to Mexican oil, and the shale yields from 80 to 100 litres of crude oil per ton using surface samples, so that larger yields could be expected at greater depths. Treatment could consist of dry distillation, which would be simple as the limits of distillation are small, or steam distillation, which would be very expensive. There is a new solvent method, however, which consists of treating the shale by solvents such as kerosene, heavy oil, paraffin, carbon disulphide, which extracts the oil and leaves the residue. To separate the useful products of this pasty solution it suffices to add an aqueous solution of sodium carbonate or soap, which separates the layer of solvent laden with oil from the sand and other impurities. Volatile solvents can be recovered afterwards.

CORRESPONDENCE

"THE UNQUALIFIED CHEMIST"

Sir,—The position to-day of chemists who have no degrees is in many respects similar to that of a large number of dentists prior to the enactment of the Dental Act of 1921. Just as to-day there are hundreds of men with theoretical knowledge, manipulative skill, and years of practical experience, but with no degrees, successfully filling important posts as chemists, so there were hundreds of men practising dentistry of equal ability to the qualified dentists.

The Dental Act sought to do for dentists what the Institute of Chemistry is, to a large extent, doing—and quite rightly—for chemists, viz., to ensure—as far as examinations can ensure—that those practising the science should have attained a definite standard of ability.

But whereas the framers of the Dental Act realised that it was in a great many cases both impractical and unnecessary for men with years of practice to sit for the same examinations as those just starting in the profession, *and made provision accordingly*, the Institute of Chemistry is, apparently, not disposed to take such a just and practical view as regards those who, as chemists, have proved their ability by a greater test than academical examinations—the test of time and experience.

If the Institute really seeks, as it professes, to help the *bona fide* chemist, it must seem to many that to work in the direction of getting the older and more experienced men regarded as unqualified simply because they have no degrees—and thereby minimise their chances of advancement—is hardly in accordance either with its protestations or with justice.—I am, Sir, etc., VH_2

A QUERY

Sir,—I take the liberty of enquiring whether one of the members of your *Journal* could advise me regarding a continuous centrifugal separator which would take only the solids (fine dirt) out of a fatty emulsion. The centrifugal used was only capable of effecting separation of a batch having an equivalent amount of dirt to that which the machine was capable of retaining (about 4 lb.) and choked after running for a quarter of an hour, when it had to be dismantled and cleaned; therefore, this is an impracticable machine for our purpose.

The fatty emulsion is the diluted grease recovered from the wool washers' effluent, which floats on the waters by the action of the nascent oxygen from the decomposition of hypochlorous acid, a very successful and infallible flotation process. When floated off the residual waters, the volume of recovered grease is 160 gallons at $9\frac{1}{2}$ lb. equals 1007 lb., containing 31 per cent. fat, 12 per cent. dirt, and 57 per cent. water, which varies from 0·25–1 g. and a litre. This is the recovery from the effluents of the two first bowls of a Leviathan machine, washing 9 bales of wool in an eight-hour day. This concentrated mixture was diluted to 3 or 4 times its volume and heated to 95° C., then stirred by live steam to give it uniformity for the separator. It was slightly acid just above neutral, and proved the dirt to be free—this coincided with the experience we had with the centrifugal.

I am afraid that if a hot filter press were used the acid would play havoc with the filter cloths, and here in Australia the washing and attention required to keep them in order would be a great worry. Water and oil make a bad combination to go through a filter, and it seems to me almost impossible to obtain the desired effect.

If the emulsion is free from foreign matters—which in fact are protective colloids—the fat will dissociate from the water by heat with the addition of a little acid.

I hope my appeal for advice on this matter will be accepted by the *Journal*, for it may start the principle of the *Journal* being the medium to assist members and others with advice when they are up against a problem and may elucidate problems which would interest many. Might I suggest that you even devote a special page (printed on a different coloured paper so as to differentiate from the main body of the *Journal*) in your *Journal* for this purpose. Here in Australia we are very inefficiently informed of mechanical appliances relating to chemical industries.

Trusting soon to have a reply in answer to my request,—I am, Sir, etc., JEAN DE RAEVE

Sydney, Australia
Feb. 20, 1924

THE INSTITUTE OF CHEMISTRY

Sir,—The letters you have published on the subject of the Institute of Chemistry seem to me to be rather spoiled by what I may call a touch of rancour. Your own subtle references to a certain vulpine bolshevist pleased me much, but I have to confess that I, too, am one of the foxes though I have nothing but praise for the grapes.

Seriously, then, and without in any way wishing to cast doubts on the good intentions of the Institute, may I ask what provision exists for the case of the man trained as articled pupil (exactly as your other letters describe) who has attained to a position of responsibility and yet who cannot afford time for intensive study nor for exams., even if he still have the power to pass set tests? It must be admitted that there is a time of life for passing exams. which passes away about the thirties, and after that time it is the experience and knowledge, tact and organising ability that find responsible positions for chemists.

Will not the Institute state clearly whether or no there is a means whereby some of the older people can lend their support to what they all consider to be the accredited Institution of British Chemistry?—I am, Sir, etc., R. G. JOHNSTON,
Scientist in charge

Midland Laboratory Guild, Ltd.,
Metallurgical Laboratories,
King Alfred's Place,
Broad Street, Birmingham
March 28, 1924

ROTATORY DISPERSION

Sir,—Dr. E. E. Walker, in his letter of March 28 rather misses the point of my remarks in the discussion at the Chemical Society on March 20. As I understand the present position of the numerous investigations of rotatory dispersion, it can be summarised as follows :—

(*a*) For a long time it has been recognised that a mixture of two substances of unequal dispersive power and of rotatory powers of opposite sign will exhibit the phenomenon of anomalous dispersion.

(*b*) The most refined methods at present employed for the determination of rotatory power give results which can be expressed by not more than two terms of the Drude dispersion equation.

(*c*) The majority of substances apparently require only one term of the Drude equation to express adequately their dispersive powers.

(*d*) The hypothesis has been advanced that in the case of a substance requiring two terms of the equation to express its dispersive powers, the substance in the chemical sense is heterogeneous, and is assumed to be a mixture of dynamic isomerides.

(*e*) The greatest refinement of polarimetric measurements, however, hardly allows of a distinction between the cases in which one term of the Drude equation is sufficient and those in which two terms are required to express the rotatory dispersion, except when the two terms are of opposite sign, the case which corresponds to "anomalous rotation."

(*f*) Attempts to ascribe chemical significance to varieties of rotatory dispersion are becoming increasingly difficult as facts accumulate.

(*g*) Dynamic isomerides in the case of tartaric acid and its derivatives have not been isolated, but merely postulated.

It is true that the hypothesis of the existence of dynamic isomerides does account for the fact of the rotatory dispersion of tartaric acid and its esters as outlined in Dr. Walker's letter, but is this hypothesis necessary ? The theory underlying the Drude equation is that the rotatory dispersion is controlled by absorption bands: the addendum advanced by several authors that each absorption band indicates (or belongs to) a distinct dynamic isomeride is not supported by the experimental results so far obtained.

It therefore appears to me that Dr. Austin, Prof. Lowry and their collaborators are unwise to allow the exuberance of their enthusiasm for theoretical views to tempt them to write as if the existence of these dynamic isomerides, which have been so often postulated, has been definitely detected. It seems unscientific to do so, and is a practice, in my opinion, to be deprecated.

Messrs. Austin and Carpenter are to be congratulated on their experimental results obtained with *solutions* of the methylene derivatives of tartaric acid, but these do not, in my opinion, throw any light on Dr. Astbury's deductions from results obtained by X-ray examination of tartaric acid *crystals*.—I am, Sir, etc.,

ROBERT H. PICKARD.

PERSONAL AND OTHER ITEMS

Dr. J. I. O. Masson, M.B.E., Reader in inorganic chemistry at University College, London, has been appointed professor of chemistry and director of the Science Department in the University of Durham. Dr. Masson is one of the secretaries of the Chemical Society.

We are pleased to announce that Mr. William Cullen has become an honorary LL.D. of the University of the Witwatersrand, an honour in which he is preceded only by General Smuts.

The next meeting of the London Section will be held in the Royal Institution and Prof. H. E. Armstrong, F.R.S., will give an address on Sir James Dewar as an experimental inquirer in interpretations of his work. The meeting is open to Fellows of the Chemical Society, who are cordially invited.

The Council of the British Association has resolved to nominate Dr. Horace Lamb, F.R.S., formerly Professor of Mathematics in the University of Manchester, as President of the Association for the Southampton Meeting in 1925.

The centenary of J. Pullar and Sons, the largest dyeing and cleaning company in the world, was celebrated on March 26, in Perth. It is interesting to recall that this firm was the first to use the first coal-tar dyestuff when it was made by Perkin in 1856.

W. E. Sanger, who died recently in Chicago, was an authority on the technology of glycerin manufacture, and had done much work on the chemical engineering of various branches of the oils and fats industry.

The death is announced of Prof. H. Wolpert, formerly director of the Prussian Landesanstalt für Wasserhygiene, and co-author, with his father, of a large treatise on the theory and practice of ventilation and heating.

Prof. M. Gildemeister has succeeded the late Prof. V. Garten in the chair of physiology in the University of Leipzig.

Dr. H. Sandqvist, lecturer in the chemistry and technology of wood at the Hernösand Technical *Hochschule*, has been appointed professor of chemistry and pharmacy in the Pharmaceutical Institute of Stockholm.

The Oppau Explosion

The programme of the meeting of the Faraday Society to be held on Monday, April 14, in the Rooms of the Chemical Society, will include a Report on an investigation of the chemical, physical and explosive properties of Oppau ammonium sulphate-nitrate by Sir R. Robertson and Dr. G. Rotter, with Appendices by Dr. H. H. Thomas, Mr. A. L. Hallimond and Sir W. Bragg. A short introduction by Sir R. Threlfall will precede the report, giving briefly the conclusions of the Chemistry Research Board as to the causes of the Oppau explosion in 1921. Advance copies of the papers will be available (price 2s. to non-members) on application to the Faraday Society, 10, Essex Street, Strand, W.C. 2.

REVIEW

Cobalt Ores. *By* E. Halse. *Monograph of the Imperial Institute. Pp.* 54. *London: John Murray. Price* 3*s.* 4*d.*

"Cobalt Ores" is a compilation of information which has been published during recent years on the occurrences and sources of supply of cobalt, both within the Empire and in foreign countries. It includes such meagre and statistical information as is available and also provides a useful list of references, general and geographical, to the literature on the subject.

That part of the monograph dealing with the sources is handled well, but one is disposed to question the accuracy of some of the remarks which occur in the introductory chapter. For instance, the author says that "nickel and cobalt may be regarded as interchangeable for many purposes"; one cannot recall any commercial or industrial use of cobalt where nickel could be substituted, although it is possible that, were cobalt cheaper, it might replace nickel for electro-plating.

The author appears to be somewhat pessimistic regarding the future of cobalt unless it can be produced at a lower cost. The chief use for cobalt still lies in the ceramic industry, but, notwithstanding an actual increase in price during very recent years, its application is appreciably extending, especially in the form of metal; witness its use in the manufacture of permanent magnets to replace tungsten and other steels.

REPORT

Report on the Present State of Knowledge of Accessory Food Factors (Vitamins). *Second edition, revised and enlarged. Compiled by a Committee appointed jointly by the Lister Institute and the Medical Research Council. H.M. Stationery Office,* 1924. *Price* 4*s.* 6*d.*

To the many students of nutrition who wish for an authoritative account of the present state of knowledge of vitamins and who have not the time to follow the original literature on the subject, this report will prove most valuable. It contains practically all the material embodied in the first edition, together with accounts of research work which is being carried out by experimenters in an ever-increasing number of countries. The section on pellagra has been omitted, for whilst this is still regarded as a disease of dietetic origin, it is thought to be due to some quantitative or qualitative defect in the protein of the diet, rather than to a deficiency of some accessory food factor. It is a remarkable fact that in the early history of a subject, such as the whole study of vitamins, very little work has had to be contradicted, and that it has been found possible to reconcile the very different views on the cause of rickets, though not to explain why they are reconcilable.

Much of the earlier work on accessory food factors was necessarily undertaken to determine which foods did or did not contain the various vitamins, for the use of food substitutes during the war gave rise to very serious consideration on this point. During the last four years, however, work has been directed more to the scientific and clinical aspects of the subject. It has been possible to determine some of the physical and chemical properties of each vitamin, but no vitamin has yet been isolated, and practically nothing is known of their immediate action in the animal body.

The technique for testing for the vitamins A and B has been refined somewhat, so that more exactly quantitative comparisons can be made between different substances.

It seems to be established that the vitamin A content of the fat, milk, etc., of an animal is directly dependent on the diet, and it has been shown that this content can be greatly increased by adding cod-liver oil to a diet, otherwise poor in vitamin, such as cows receive in winter. The rich stores of this vitamin in the liver oil of the cod have been traced through intermediate animals to the diatoms eaten by the various species of copepods and other animals which form the plankton of the sea. The wide variations in vitamin content found in different samples of cod-liver oil seem to be due not so much to differences in preparation of the oil as to differences in the physiological condition of the fish when caught.

The question of the formation of vitamin A in plant tissues is dealt with, and the possibility of its growth-promoting function being due to a substance other than the rickets-preventing substance is considered. There is a short summary of its properties as at present determined, such as its solubility, stability to heat, and susceptibility to oxidation.

The more recent work on vitamin B has been chiefly chemical and physical. Its stability to oxidation has been demonstrated and some idea of the size of its molecules, or of aggregates of its molecules, has been gleaned from the fact that it will pass through permeable membranes which allow methylene blue and safranine to pass. Other work has been attempted, with varying results, on the physiological significance of vitamin B.

Similar experiments have also been carried out on vitamin C.

Perhaps the most striking part of this report is the summary of Dr. Harriette Chick's work on rickets in children in Vienna, the full account of which has been published as a separate report (No. 77 of this series). Her general conclusions are that rickets may be prevented by a diet rich in the anti-rachitic factor (which may or may not be identical with the growth-promoting vitamin A) even in the absence of sunlight, but that sunlight, such as obtains in the summer months in Vienna, prevented and even cured many sufferers from rickets when the diet was very poor in the anti-rachitic factor. Experiments performed by various workers on rats with ultra-violet light and also with sunshine have supported these conclusions. No theory of the interaction of the two factors, vitamin and sunlight, has as yet been postulated.

The report concludes with chapters on the diet of adults, the nutrition of infants, and the influence of

liet on teeth; and there is a bibliography of some ten pages, which is a significant increase on the three or four pages of the earlier issue.

The various sections of the book are interestingly written; experimental work has been accurately recorded and evidence for conflicting opinions on subjects even yet little understood has been carefully balanced. It will prove a reliable book of reference for the student of vitamins and should supply the ever-increasing demand for a sound outline of a subject which hitherto has only been obtainable in cumbersome and expensive volumes.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Dyestuffs and the German Reparation Duty

In reply to Mr. Waddington, Mr. Webb said he was aware that the price of German dyestuffs had not been reduced, but practically the whole of the German dyestuffs imported into this country during the last few months had been against contracts made prior to November 17 last, and in respect of which the German Government undertook to continue to refund the amount of reparation levy, provided that delivery were made before the end of March, 1924. The price of deliveries made after that date would have been subject to an increase corresponding to the amount of the levy. The present position was, therefore, that now the British importer pays 95 per cent. of the purchase price of any dyes imported to the German exporter, and 5 per cent. to the Customs, instead of 74 per cent. to the exporter and 26 per cent. to the Customs, as was formerly the case. Consequently no reduction in prices was to be expected.—(Mar. 20.)

COMPANY NEWS

BELL'S UNITED ASBESTOS, LTD.

A dividend is announced of 1s. 6d. per share on the ordinary shares, making a total distribution for the year of 10 per cent. It is proposed to increase the reserve by £10,000 to £38,000, and to carry forward £31,483. In 1922 the dividend was 10 per cent. and the carry forward £37,911.

BRITISH DYESTUFFS CORPORATION, LTD.

The report for the year ended October 31, 1923, reveals profits amounting to £251,422, against £102,657 in 1921-22. Depreciation is fixed at £360,025, against £411,382, the percentage allowance being the same. The fixed assets of the associated companies have been written down by £458,003 to £3,273,732, the Corporation having included £100,000 formerly held as a reserve for research. Stocks, valued on a conservative basis, stand at £1,601,708, against £1,870,000, and goodwill, patents, etc. have been reduced from £1,000,000 to £750,000 as the result of sums receivable from E. I. Du Pont de Nemours and Co.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5½d. per lb.
Potass. Chlorate	3d.—3¼d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide	4s. per lb.
Carbon Bisulphide	£24—£26 10s. per ton according to quantity.

Carbon Black	Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 10s. per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. " " 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Dull market.
Solvent	5s. per gall. 40% O.P. Dull market.
Wood Tar	£5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead	£47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7¾d.—8d. per lb. Better demand, and firmer market. London prices reported up to 9d.
Crude 60's	2s.—2s. 3d. per gall. Market stronger; better demand.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Benzole, Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Toluole—Pure	1s. 8d.—1s. 11d. per gal
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d. per gall. Few inquiries.
Middle Oil, Heavy, Standard Specification	7¾d.—8½d. per gall. according to grade and district. Market easier.
Naphtha—	
Crude	8d.—9d. per gall. Better demand. Prices show upward tendency.
Solvent 90/160°	1s. 2d.—1s. 4d.
Solvent 90/190	1s. 2d.—1s. 3d.
Naphthalene Crude—	
Drained Creosote Salts	£7—£8. Demand not so good.
Whizzed or hot pressed	£9 10s.—£12 per ton. Not much inquiry.
Naphthalene—	
Crystals and Flaked	£18—£19 per ton.
Pitch, medium soft	57s. 6d.—62s. 6d. per ton. Market dull.
Pyridine—90/140	17s. 6d.—18s. per gall. Demand well maintained.
Heavy	11s.—12s. Few inquiries.

INTERMEDIATES AND DYES

Business in dyestuffs has increased and reflects an improvement in the textile trade. Orders have been for larger quantities than of late. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 10d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 4d. per lb. Steady demand.
Acid Sulphanilic	10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4¾d.—5½d. per lb. Demand moderate.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethyaniline	2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluence—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 3d. per lb. d/d.
Monochlorbenzol	£63 per ton.
α Naphthol	2s. 5d. per lb. d/d.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.

p-Nitrophenol .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 2d. per lb. d/d.
p-Phenylene Diamine .. 10s. 6d. per lb. 100% basis d/d.
R. Salt .. .. 3s. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 6d. per lb. 100% basis d/d.
o-Toluidine .. .. 8½d. per lb.
p-Toluidine .. .. 3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine .. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. .. £50 per ton. Market easier.
Acid, Acetyl Salicylic .. 3s. 6d.—3s. 9d. per lb. Best known makes firmer.
Acid, Benzoic .. .. Commercial acid 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. 6d. lb.
Acid, Boric B.P. .. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric .. 19s.—21s. per lb. Advanced by 1s. per lb.
Acid, Citric .. .. 1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic .. .. 3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst. .. 6s. per lb., for 28 lb. lots.
Acid, Salicylic .. .. Prices quoted from 2s. 3d. per lb. down to 1s. 10d. for ton lots. In steady demand.
Acid, Tannic B.P. .. 3s. per lb. Market quiet.
Acid, Tartaric .. .. 1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol .. .. .. 9s. per lb. d/d.
Acetanilide .. .. 2s. 9d. per lb. for quantity. Larger supplies available.
Amidopyrin .. .. 14s. per lb. Slightly dearer.
Ammon. Benzoate .. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P. £37 per ton.
Atropine Sulphate .. 12s. per oz. for English make.
Barbitone .. .. 15s. 6d. per lb. Weak market.
Benzonaphthol .. .. 6s. 3d. per lb. Firmer.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides— Per lb.
Potassium .. .. 9d.
Sodium .. .. .. 9d.
Ammonium .. .. 10½d.
} Slightly firmer.
Calcium Lactate .. Prices vary over a wide range. Good English make can be had from 1s. 7d. to 2s. 3d. per lb.
Chloral Hydrate .. .. 3s. 9d. per lb.
Chloroform .. .. 2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate .. 6s. per lb. Little demand.
Guaiacol Carbonate .. 12s. 6d. per lb. for cwt. lots.
Hexamine .. .. 3s. 6d.—3s. 9d. per lb. for foreign makes. Weaker. Without much inquiry.
Homatropine Hydrobromide .. .. .. 30s. per oz.
Hydroquinone .. .. 4s. 3d. per lb. Foreign make.
Iron. Ammon. Citrate B.P. 1s. 11d.—2s. 3d. per lb., according to quantity.

Magnesium Carbonate—
Light Commercial .. £ per ton net.
Magnesium Oxide—
Light Commercial .. £75 per ton, less 2½%
Heavy Commercial .. £26 per ton, less 2½%
Heavy Pure .. .. 2s.—2s. 6d. per lb., according to quantity. Steady market.
Menthol—
A.B.R. recryst. B.P. .. 60s. per lb. Market firmer.
Synthetic .. .. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials .. .. Very much firmer in view of the rise in the price of quicksilver. Higher prices expected.
Red oxide .. .. 4s. 9d.—4s. 10d. per lb.
Corrosive sublimate .. 3s.—3s. 1d. "
White precip. .. .. 4s. 1d.—4s. 2d. "
Calomel .. .. 3s. 5d.—3s. 6d. "
Methyl Salicylate .. 2s. 7d.—2s. 9d. per lb. for carboys. Weaker than other salicylates.
Methyl Sulphonal .. 24s. per lb.
Paraformaldehyde .. 3s. 6d. per lb., without much inquiry.
Paraldehyde .. .. 1s. 4d.—1s. 7d. per lb. in free bottles and cases.
Phenacetin .. .. 7s. per lb. Firmer.
Phenazone .. .. 7s. 6d. per lb. for cwt. lots. Spot prices much lower than forward offers. Firmer tendency.
Phenolphthalein .. .. 7s. 3d.—7s. 6d. per lb. Firm.
Potass. Bitartrate—99/100% (Cream of Tartar) .. .. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate .. .. 1s. 8d.—2s. per lb.
Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite .. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—
B.P. Crystal .. .. 8¾d.—9d. per lb. carriage paid. English make.
Commercial .. .. 8d.—8¼d. per lb. carriage paid. English make.
Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin .. .. .. 6s. 3d. per lb.
Salol .. .. .. 3s. 9d. per lb.
Silver proteinate .. .. 10s. per lb.
Sod. Benzoate, B.P. .. 3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923 1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—
Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside .. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) .. 76s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate .. .. Market firmer. Powder 2s. 8d.—2s. 10d. per lb. Crystal at 2s. 9d.—2s. 11d. per lb. Flake 2s. 10d.—3s. 4d. per lb.
Sod. Sulphide—
Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.

Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	18s. 6d. per lb.
Tartar Emetic	1s. 4d. per lb.
Thymol	13s. 6d.—15s. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	13s. 6d. ,,	
Amyl Acetate	2s. 9d. ,,	Cheaper.
Amyl Butyrate	7s. 3d. ,,	
Amyl Salicylate	3s. 6d. ,,	
Anethol (M.P. 21/22° C.)	4s. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,	
Benzyl Alcohol free from Chlorine	3s. 3d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde Natural	15s. 6d. ,,	Cheaper.
Coumarin	20s. ,,	
Citronellol	16s. ,,	
Citral	10s. ,,	
Ethyl Cinnamate	15s. ,,	
Ethyl Phthalate	3s. 9d. ,,	
Eugenol	11s. ,,	
Geraniol (Palmarosa)	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	Advanced.
Heliotropine	8s. 3d. per lb.	
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose	21s. 6d. ,,	
Linalyl Acetate	21s. 6d. ,,	
Methyl Anthranilate	9s. 6d. ,,	
Methyl Benzoate	6s. ,,	
Musk Ambrette	52s. 6d. ,,	
Musk Xylol	19s. ,,	
Nerolin	4s. ,,	
Phenyl Ethyl Acetate	12s. 6d. ,,	
Phenyl Ethyl Alcohol	16s. ,,	
Rhodinol	57s. 6d. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. [illegible] ,,	
Vanillin	25s. 3d.—26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	Dearer.
Aniso Oil	2s. 7½d. per lb.	Firmer market forward.
Bergamot Oil	17s. per lb.	
Bourbon Geranium Oil	32s. ,,	
Camphor Oil	75s. per cwt.	
Cananga Oil, Java	9s. 9d. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Cassia Oil, 80/85%	9s. 3d. per lb.	
Citronella Oil— Java 85/90%	5s. 3d. ,,	
Ceylon	3s. 9d. ,,	
Clove Oil	8s. 4½d. ,,	
Eucalyptus Oil 70/75%	2s. 3d. per lb.	
Lavender Oil— French 38/40% Esters	26s. per lb.	Advan[illegible]
Lemon Oil	3s 4d. ,,	
Lemongrass Oil	2¾d. per oz.	
Orange Oil, Sweet	13s. per lb.	Ad[illegible]
Otto of Rose Oil— Bulgarian	30s. per oz.	
Anatolian	24s. 6d. per [illegible]	
Palma Rosa Oil	18s. 6d. per lb.	Very short supply.
Peppermint Oil— English	75s. per lb.	Advanced 5s. per lb.
Wayne County	21s. per lb.	Again advanced.
Japanese	18s. per lb.	but very little being offered.
Petitgrain Oil	9s. 9d. per lb.	Advanced.
Sandal Wood Oil— Mysore	25s. per lb.	
Australian	21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—Applications

Bingham, and Huntington, Heberlein and Co. Apparatus for separating granular materials from water. 7155. Mar. 20.

Brégeat. Purification of products using alcohol as a solvent. 7086. Mar. 19. (Austria, 15.12.23.)

Carlsson. Manufacture of finely-dispersed substances. 7284. Mar. 21. (Sweden, 6.2.24.)

Davidson and Winzer. Kilns. 7249. Mar. 21.

Field. Recovering solids. 7082. Mar. 19.

Fritz. Hydrating, heating, and refining machines. 6820. Mar. 17.

Fulcher. Straining or filtering apparatus. 7040. Mar. 19.

Golding, Pritchard, and United Alkali Co. Means for effecting absorption of gases. 7268. Mar. 21.

Imray (International Combustion Engineering Corp.). Pulverizing-mills. 6968. Mar. 17.

Koppers Coke Oven Co., Ltd. (Koppers). Tunnel ovens and kilns. 7174. Mar. 20.

Lemmens. Filters. 7066. Mar. 19.

Lomax. Preparation of solutions of solid or other soluble materials. 7337. Mar. 22. (U.S., 4.4.23.)

Mayhew and Ramsay. Grinding, milling, and pulverizing apparatus. 7354. Mar. 22.

Pink. Apparatus for separating liquids of different specific gravity. 7181. Mar. 20.

Weeker. Separating volatile substances from non-volatile etc. substances. 7091. Mar. 19. (Ger., 20.3.23.)

I.—Complete Specifications Accepted

24,045 (1922) and 5348 (1923). Woodall, Duckham, and Jones (1920), Ltd., and A. M. Duckham. Annular muffle furnaces or ovens. (212,585.) Mar. 26.

34,142 (1922). Sonsthagen, Wood, and Keenok Co., Ltd. Emulsifying-apparatus. (212,642.) Mar. 26.

8531 (1923). Arpin. Separating mixed materials. (212,752.) Mar. 26.

17,329 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges.). Electrical precipitation of suspended particles from gaseous fluids. (212,811.) Mar. 26.

29,591 (1923). Naamlooze Vennootschaap Montaan Metaalhandel. Process for re-activating adsorption media. (207,547.) Mar. 26.

II.—Applications

Charpentier and Henneberg. Manufacture of fuel alcohol. 7152. Mar. 20. (Fr., 20.6.23.)

Charpentier and Henneberg. Manufacture of fuel alcohol. 7153. Mar. 20. (Fr., 10.12.23.)

Donald. Drying peats etc. 7231. Mar. 21.

Dupuy. Manufacture of artificial fuel. 6783. Mar. 17. (Fr., 29.3.23.)

Edser, and Minerals Separation, Ltd. Flocculation and briquetting of coal. 6933. Mar. 18.

Fox and Malone. 7007. See XXIII.

Graer. 6751. *See* VII.

Hackford and Koopman. Combustion of gaseous fuel. 7160. Mar. 20.

Hahn. Utilisation of liquid fuels. 6791. Mar. 17.

Hirchberg. Treatment of hydrocarbon oils. 6817. Mar. 17.

Illingworth Carbonization Co., Ltd., and Illingworth. Drying and mixing coals. 6835. Mar. 17.

Lowe. Retort settings for distillation of coal. 7330. Mar. 22.

Perten. Manufacture and regeneration of decolorising charcoal. 6826. Mar. 17. (Czecho-Slovakia, 19.3.23.)

Urbain. Manufacture of agglomerated carbonaceous material. 7033. Mar. 19. (Fr., 25.6.23.)

Urbain. Treatment of gases etc. 7129. Mar. 20. (Fr., 13.7.23.)

Urbain. Purification of distillation gases etc. 7230. Mar. 21. (Fr., 13.10.23.)

Urbain. Apparatus for treating gases etc. 7305 and 7379. Mar. 22. (Fr., 9 and 26.1.24.)

Wisner. Process of evolving hydrocarbon from fuel. 6816. Mar. 17. (U.S., 11.6.23.)

Zuyderhoudt. Low-temperature carbonisation. 7262. Mar. 21.

II.—Complete Specifications Accepted

20,152 (1922). Remfry. Treatment of liquid hydrocarbons and more especially cracked spirit. (212,500.) Mar. 26.

34,513 (1922). Illingworth. Manufacture of briquettes. (212,663.) Mar. 26.

34,745 (1922). Seigle. Distillation and depolymerisation of liquid or liquefiable hydrocarbons. (190,723.) Mar. 26.

34,931 (1922). Pickard. Production of explosive mixture for internal-combustion engines. (212,669.) Mar. 26.

10,526 (1923). Fairweather. Apparatus for the fractional distillation of oils from oil-shale or similar material. (212,770.) Mar. 26.

16,950 (1923). Paul-Schiff and Co., and Borchers. Arc-lamp carbons and electrodes. (201,537.) Mar. 26.

18,947 (1923). Klotzer. *See* III.

28,759 (1923). Marks (Siemens und Halske Akt.-Ges.). *See* XXIII.

III.—Complete Specification Accepted

18,947 (1923). Klotzer. Method of extracting tars and gases from bitumen-containing materials. (212,828.) Mar. 26.

IV.—Applications

Beckett, Thomas, Tonkin, and Scottish Dyes, Ltd. Dyestuffs and intermediates. 7255. Mar. 21.

British Dyestuffs Corporation, Ltd., and Hodgson. Manufacture of hydroxybenzaldehydes. 7057. Mar. 19.

V.—Application

Moses. Paper products. 7342. Mar. 22.

VI.—Applications

Ashworth. Process for finishing yarn etc. after dyeing. 6902. Mar. 18.

Farbwerke vorm. Meister, Lucius, und Brüning. Dyeing wool. 7083. Mar. 19. (Ger., 19.3.23.)

McCullum and Nelson. Dyeing fabrics. 7322. Mar. 22.

VI.—Complete Specifications Accepted

8079 (1923). Courtaulds, Ltd., and Wood. Apparatus for use in dyeing, or otherwise treating with liquid, fibrous materials in skeins. (212,749.) Mar. 26.

16,134 (1923). Gentner. Method of colouring fibrous materials. (212,804.) Mar. 26.

26,006 (1923). Ness. Apparatus for dyeing textiles. (205,812.) Mar. 26.

VII.—Applications

Chemische Fabrik Von Heyden Akt.-Ges. Manufacture of soluble antimony compounds. 7378. Mar. 22. (Ger., 23.3.23.)

Dicker (Permutit Co.). 6829. *See* XIX.

Graer. Production of pure hydrogen gas. 6751. Mar. 17. (Belgium, 17.3.23.)

VII.—Complete Specification Accepted

10,133 (1923). Sulfur Akt.-Ges., and Franck. Process and apparatus for the manufacture of sulphuric acid. (212,768.) Mar. 26.

IX.—Application

Rigby. Manufacture of cement in rotary kilns. 7097. Mar. 20.

X.—Applications

Allmänna Ingeniörsbyran H. G. Torulf. Means for sintering ores. 6929 and 6985. Mar. 18. (Sweden, 22.8.23.)

Brymbo Steel Co., Ltd., and Hollings. Heat-treatment of silicon steel. 7208. Mar. 21.

Dicker (Chief Consolidated Mining Co.). 6830. Mar. 17.

Heal, and Metals Production, Ltd. Smelting metalliferous materials. 7064. Mar. 19.

McMorland. Flux for soldering etc. 6905. Mar. 18.

New York Zinc Co., Inc., and Wade. Dehydrating minerals. 6953. Mar. 18. (U.S., 28.3.23.)

Stig. Production of alloyed steel etc. with chromium, manganese, etc. 7374. Mar. 22.

X.—Complete Specification Accepted

28,208 (1922) and 6099 (1923). Keet. Concentrators for ores. (212,598.) Mar. 26.

860 (1923). Rowley and Rowley. Blast furnaces. (212,685.) Mar. 26.

8396 (1923). Mumford and Butterworth. Soldering aluminium. (212,751.) Mar. 26.

17,252 (1923). Soc. Anon. des Hauts Fourneaux, Forges, et Aciéries de Pompey. Process in the manufacture of manganese steels. (201,539.) Mar. 26.

XI.—Applications

Burnett and Haddon. Accumulator grids or plates. 7061. 7062. Mar. 19.

Burnett and Haddon. Accumulators or storage batteries. 7063. Mar. 19.

Edridge. Galvanic batteries or cells. 6775. Mar. 17.

XI.—Complete Specification Accepted

17,329 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges.). *See* I.

XII.—Application

Weygang. Manufacture of soluble or miscible oils, greases, and fats. 7178. Mar. 20.

XIII.—Applications

Carr. Composition for manufacture of linoleum etc. 7005. Mar. 19.

Marston. Transfer ink for producing indelible markings upon fabrics. 6950. Mar. 18.

Pollak. 7297. *See* XX.

XIV.—Applications

Barber. Methods of covering surfaces with india-rubber etc. 6796. Mar. 17.

Jeffrey. Manufacture of rubber compositions from latex. 6954. Mar. 18.

XIV.—Complete Specification Accepted

3712 (1923). Hopkinson. Mixing compounding ingredients with rubber latex etc. (193,044.) Mar. 26.

XV.—Application

Kernot. Manufacture of glue, gelatin, and meal from fish offal, etc. 6943. Mar. 18.

XV.—Complete Specification Accepted

15,900 (1923). Tapparelli. Radio-active hides and skins, leather, furs, and the like. (212,803.) Mar. 26.

XVII.—Complete Specification Accepted

11,312 (1923). Vereinigte Mautner'sche Presshefe-Fabriken Ges. *See* XVIII.

XVIII.—Applications

Baker. Frothing of liquids. 7171. Mar. 20.

Distillers Co., Ltd., and Meyer. Dehydrating alcohol. 7361. Mar. 22.

XVIII.—Complete Specification Accepted

11,312 (1923). Verinigte Mautner'sche Pressbefe-Fabriken Ges. Process for the clarifying and purifying of molasses for the manufacture of compressed yeast. (196,926.) Mar. 26.

XIX.—Complete Specifications Accepted

Daus. Process for making preserved foods. 7307. Mar. 22.

Dicker (Permutit Co.). Treatment of glauconite for water-softening. 6829. Mar. 17.

Kernot. 6943. *See* XV.

Lainfiesta. Flavouring extract. 7070. Mar. 19.

Oelwerke Noury & Van der Lande Ges. Treatment of meal or flour etc. 7092. Mar. 19. (Ger., 19.3.23).

XX.—Applications

British Dyestuffs Corporation, Ltd., and Hodgson. 7057. *See* IV.

Naef & Co. Manufacture of dl-nerolidol. 6824. Mar. 17. (Swiss, 22.3.23).

Naef & Co. Manufacture of farnesol. 6825. Mar. 17. (Swiss 22.3.23).

Pollak. Manufacture of condensation products from urea etc. and formaldehyde. 7297. Mar. 21. (Austria, 31.3.23.)

Standard Development Co. Manufacture of metallo-organic compounds.

XX.—Complete Specifications Accepted

14,282 (1923). Durand und Huguenin Akt.-Ges. Manufacture of highly-chlorinated hydroaromatic products containing nitrogen. (198,676.) Mar. 26.

17,466 (1923). Soc. Chimique des Usines du Rhône. Process for the preparation of diethylchloracetamide. (209,706.) Mar. 26.

XXIII.—Applications

Brown. Automatic apparatus for volumetric analysis. 7006. Mar. 19.

Fox and Malone. Gas-analysis apparatus. 7007. Mar. 19.

Scholes. Calorimeters. 7008. Mar. 19.

XXIII.—Complete Specification Accepted

28,759 (1923). Marks (Siemens u. Halske Akt.-Ges.). Apparatus for testing gas mixtures. (212,852.) Mar. 26.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—

Argentina: Paper (9401/F.L./M.C./A. 2). *Australia*: Hardware, glassware (324); Ironmongery, builders' hardware, cutlery (325); *Brazil*: Iron, paint, cement (352); *Greece*: Sugar (334); *Latvia*: Portland cement, iron, coal tar, copper, asbestos powder (9029/F.R./G.P.); *Netherlands*: Hardware tools (341); *Norway*: Shipbuilding material (345); *Spain*: Machinery and raw materials for the manufacture of paper and of earthenware (348); *Sweden*: Sulphate of alumina (349); *Turkey*: Hardware (350).

German Industry in February

According to a report by H.M. Commercial Secretary, Berlin, economic life in Germany is slowly recovering from the decline which occurred late in 1923. Output in the basic industries increased, unemployment decreased, prices fell slightly, and trade expanded. The coal industry is still in a poor state, and sales of potash have not improved, despite the reduction of prices. In the iron and steel industry, high freightage and Belgian and French competition are serious difficulties. No change is recorded in the chemical industry, and working hours may be extended and the number of workers reduced. World market prices are still lower than those prevailing in Germany. Home trade in dyes improved with greater activity in the textile industry. The glass industry is seriously depressed, but the leather industry is doing well.—(*Bd. of Trade J.*, Mar. 20, 1924.)

Trade Information

The Plauson Experimental Colloid Mill.—The Plauson Mill and Filter Press Co., Ltd., of 17, Waterloo Place, Pall Mall, S.W. 1, now produces a small colloid mill of less expensive design, adapted to the treatment of small quantities, and primarily intended to facilitate research and the application of colloid chemistry to industrial purposes. The rotor has a peripheral speed of 4000 f.s. and with charges of about 1 litre requires about 10 h.p. to drive, whilst 15 h.p. will cover most possible uses. The weight is approximately 3½ cwt., the driving pulley is 4 in. in diameter and the normal working speed 4750 r.p.m. Expensive foundations are not required. In addition to its functions as a superfine grinder, intensive mixer, etc., on a research scale it has an output capacity for most emulsions on a factory production scale. Continuous automatic circulation in conjunction with feed tanks can be employed for large outputs, or intermittent hand feeding for research operations. Difficult solutions and several chemical reactions may be accelerated. The Plauson colloid mill can be seen and tried in London and Manchester.

B. Laporte, Ltd., Luton.—We are requested to state that the recent issue of shares by B. Laporte, Ltd. has been considerably over-subscribed by the shareholders and their friends.

Messrs. Ernest Scott & Co., Ltd., Engineers and Messrs. George Scott & Son (London), Ltd., announce their registered and head offices have been removed from Kingsway House, Kingsway, London, W.C. 2 to their works at Bradfield Road, Silvertown, London E. 16, which will now be their sole address in London.

EDITORIAL

RARELY can an address before one of the Sections of this Society have opened so impressively or been presented on such classic ground as that delivered by Prof. H. E. Armstrong, F.R.S., before the London Section in the Royal Institution on Monday evening. Before a word was spoken, slides of a giant American airship were shown on the screen, followed by one of Sir James Dewar in his laboratory. Dewar's work, said Prof. Armstrong, made that airship possible. In this way opened the address on Sir James Dewar as an experimental inquirer. The realisation that Dewar himself, not very long ago, had worked in the same building, gave added force to Prof. Armstrong's remarks, and, as experiment followed experiment, and the significance of Dewar's work became clearer and clearer, regret grew that the audience was not larger still. The lecturer pointed the moral with no little pungency, and although some might not take to heart the characteristic quotation from that delightful essay in which Montaigne describes how a young woman who had grown accustomed to carrying a calf found herself unable to forego her burden, even when the calf had become an ox, yet the reference to a calf of Scandinavian breed left no doubt as to the meaning. Whether we worship at the ikon of hydrogen-ion concentration or not, it is good that we have at least one douhter among us, for too much acquiescence is not conducive to progress, and a theory is an invitation to attack. To far too many, chemistry consists in following the " tables " and " bringing it down in group two," and one cannot but regret a recent complaint that some young chemists seemed to be limited in scope entirely by text-book information. A routine analysis can quickly be learnt by any intelligent boy or girl—as the British Aluminium Company proved long ago with routine analyses of bauxite—but of how little avail is text-book knowledge when something goes wrong in the works, when a new material, with all sorts of unknown impurities, has to be examined, if it is unaccompanied by the ability to make deductions from scanty evidence, to foresee possibilities, to ask the question " Why," and answer it. Nature herself, so simple in her complexity, is always trying experiments and forgets in one success a thousand failures. In the vast field of science nothing grows save at a price, and not by " hugging an ox " will advance be made. Long ago, another Sceptical Chemist wrote: " Having entertained a suspicion that the vulgar principles were . . . lesse considerately deduced from chymical operations, than was believed, it was not uneasie for me both to take notice of divers phænomena, overlooked by prepossest persons, that seemed not to suite so well with the . . . doctrine; and to devise experiments likely to furnish objections against it . . ."

* * *

The speech of Sir William Alexander, at the Fifth Annual General Meeting of the British Dyestuffs Corporation, is full of interest. He announces his forthcoming retirement from his position as Managing Director, and leads us to assume that negotiations for the appointment of his successor are already in progress. The composition of the Board of this company has been criticised from time to time, but if our memory be accurate, even the most vigorous of the critics have testified to the business ability of the chairman. We are in entire agreement with his statement that it is to the men who are intimately associated with the business from day to day that we must ultimately look for success. The board needs an infusion of such men; it is the men to whom we must look for success whom the shareholders will expect to guide the policy of the company; moreover, the men whose good sense and knowledge of the details of the business will make the difference between success and failure deserve the responsibility and the distinction of seats on the board. There must be some prizes or the lottery of industrial science will not attract a sufficient number of the junior men into it. Although the progress made by this company during the last two years is notable, the outlook for British dyestuffs as an industry is not one of the brightest. Dyestuffs are now—from a chemical point of view—a very chance body of compounds; they are the highly coloured derivatives of benzene, naphthalene, anthracene and some other fundamental substances. Compounds which are closely allied chemically but not highly coloured are excluded from the industry. But the chemist cannot be as illogical

and capricious as the manufacturer; he knows that some of the weaker brethren, the lightly tinted or the colourless ones, are made by similar reactions, and will in many cases behave similarly when treated by acids, by azo, izo and ozo groups. These uncoloured substances include many compounds of value as drugs, disinfectants, perfumes and reagents. From the point of view of the chemist the chemistry of dyestuffs is the chemistry of benzene derivatives, and we may go further and say that every dyestuff chemist must have a good knowledge of organic chemistry, and that what is essential to him as a dyestuff chemist will be very valuable to him if he is called upon to make ionone or coumarin, aspirin or Bayer 205. The dyestuffs and all other synthetic organic chemicals are intimately connected together in this way, and it must be remembered that of all these synthetic organic compounds the only ones manufactured on a really large scale are the dyestuffs. It is the dyestuff industry that provides the trained organic chemist with the means of earning a livelihood, it is the dyestuff chemist who can—as Sir William Alexander explains—undertake research in perfumes and disinfectants. The Germans before the war dominated the manufacture of dyestuffs; for this reason, and this reason alone, they were dominant in many other branches of organic chemistry. At the moment we have a living, even a vigorous dyestuffs industry and while this has grown up during the last six or eight years we have attained a position in the pure science of organic chemistry which we never had before.

* * *

Our dyestuffs industry is vigorous but young; it is a child which promises to be as successful as any man, but it has neither the man's experience nor resources nor friends. If the Government allows the dyestuffs industry to be destroyed or even seriously crippled by foreign competition a grievous blow will have been struck at British organic chemistry. We shall speedily lose the opportunities for research in photographic developers, in drugs and other pharmaceutical requirements. We shall again become dependent on Germany for all synthetic organic compounds. And it is to organic chemistry that the future of civilisation must look; the proportion which inorganic bears to organic steadily gets less and less. Whether we are free traders or protectionists, colour-makers or colour-users, we ought not to neglect consideration of the very important results which will follow from a blow to the dyestuff industry. Many valuable drugs are closely involved in the manufacture of dyestuffs; much teaching of organic chemistry will be of value to our industries and professions if the dyestuffs be assisted a little longer and will be wasted if the dyestuff research be again allowed to be a German preserve. What an amount of employment has been afforded by the dyestuffs makers in Germany! If a long view is taken of the situation we shall have employment in the dyestuff, drug, photographic and perfume industries steadily increasing here.

EVAPORATING AND DRYING PLANT

(Continued)

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

Continuous Driers

To obviate these heat losses, and the time and cost of charging and discharging, the continuous drier has been developed in a number of forms, such as the tunnel drier, the tube drier, the drum drier, and the spray drier.

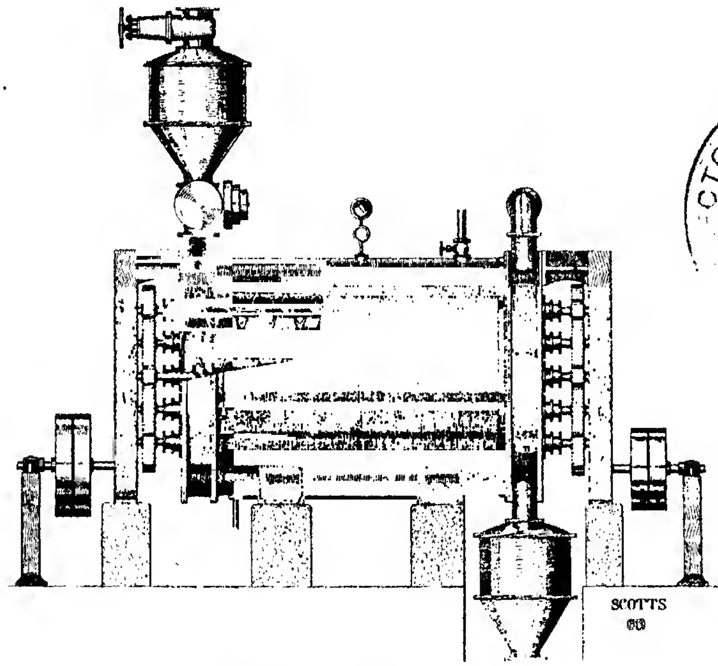
Tunnel driers consist of long tunnels, through which the goods are passed. Sometimes the goods, suitably mounted on trucks, are admitted in the wet condition at one end of the tunnel, and, after drying, discharged at the other. The flow of the hot air or gases through the tunnel may be either in the direction of the movement of the goods, giving parallel flow, or in the opposite direction, which is term d counter current flow.

Parallel flow is generally employed when the goods leaving the tunnel have to possess a definite amount of moisture. This method permits of a very accurate control and regulation of the temperature and humidity of the heating medium. When the goods, on leaving the plant, are not required to contain a definite amount of moisture, the counter-current flow is preferable, because, in this method, the driest medium is brought into contact with the driest material. In plants of the tunnel variety the heating may be done directly, by flue gas, if the material will not be damaged by being thus heated, or by heated air. Sometimes in the counter-current type of plant the heating medium is introduced into the tunnel at a point about one-third the length of the tunnel from the discharge end. Cold air enters the tunnel at the discharge end, and, passing over the dried goods at this end of the plant, cools them, and becomes preheated before entering the heating chamber. A difficulty with this type of drier is to ensure a uniform flow of the drying medium through the goods, and many ingenious devices having this object in view have been developed. A recent patent illustrates the trouble taken in this direction. In this plant the carriages are each provided with a partition at the forward end, attached to the floor of the truck, which is capable of movement across the rails. A mechanism is fitted along one wall of the tunnel, which can move all the even numbered trucks, so that the right hand edges of the floor and partition are in contact with the right hand wall of the tunnel, and all the left hand edges of the floor and partition of the odd numbered trucks are in contact with the left wall. By rotation of this mechanism a complete change over can be effected in these sets of trucks. The roof of the tunnel slopes gently downwards towards the discharge end, and leakage between the roof and the partition walls is prevented by placing on the top of the latter a layer of granular material such as sand. Metal plates attached to the floor of the trucks dip into troughs of sand on the tunnel walls, and thus prevent leakage of the heating medium into the space below the floor of the truck. By these devices

the heating medium is compelled to flow in a zig-zag path through the goods, and by changing the positions of the trucks the direction of flow through the goods can be reversed.

Fig. 7 (reproduced on p. 354 of the issue for April 4) illustrates a continuous drier manufactured by Blair, Campbell, and McLean suitable for dealing with grains, oil, seeds, etc. In this plant a reel with its axis horizontal revolves inside a steam-jacketed cast iron trough. The reel is made of two cast-iron hollow discs, connected together by a number of parallel tubes. Angle bars extending between these discs, and rigidly attached thereto, carry the shovels, which at the wet end of the machine are made of bronze. In large and long reel plants, supporting plates are fitted at intermediate points in the reel. Steam is fed into the jacket of the first section of the trough, and passes by means of U bends from section to section, the condensate being removed at suitable points. The reel is also heated by steam admitted through one trunnion into the first disc, from which it passes, by means of the tubes, to the second, which is provided with a device by which the condensate can be removed through the second trunnion. The grain is fed into the cooler end of the plant by means of a specially designed screw conveyor, and is discharged at the other end through a chute placed well above the axis of rotation of the reel. The drier is provided with a cast-iron roof which is connected to a wooden chimney, in which there is a catch-all to prevent any moisture falling back on to the grain. Brass inspection doors are fitted along the whole length of the drier on each side of the roof. The lower portion of the machine is surrounded by a hardwood box, and the air in the space thus formed, after being heated, is led through suitable ducts into the trough.

Another continuous machine suitable for drying soaps consists of a number of endless belts placed one above the other. Each belt runs inside its own casing, which is connected at either end to the casing immediately above and below it. The material, entering at one end of the machine, falls on to the upper surface of the top belt, by which it is carried to the other end of the plant and discharged into a chute. This conveys the material to the upper surface of the second belt, by which it is carried back to the charging end, where it is again directed through a chute on to the upper surface of the third belt, which carries it to the outlet of the plant. Hot air is admitted to the lowest casing at the discharge end of the plant, and, flowing to the other end, passes up through the chute into the second casing, from which it passes to the first casing through the first chute, being ultimately discharged at the charging end of the plant. If parallel flow is desired, the air passes through the casings in the same direction as the material. Fig. 8 illustrates a similar type of plant manufactured by G. Scott and Sons, but in this case the material is moved by a series of conveyors

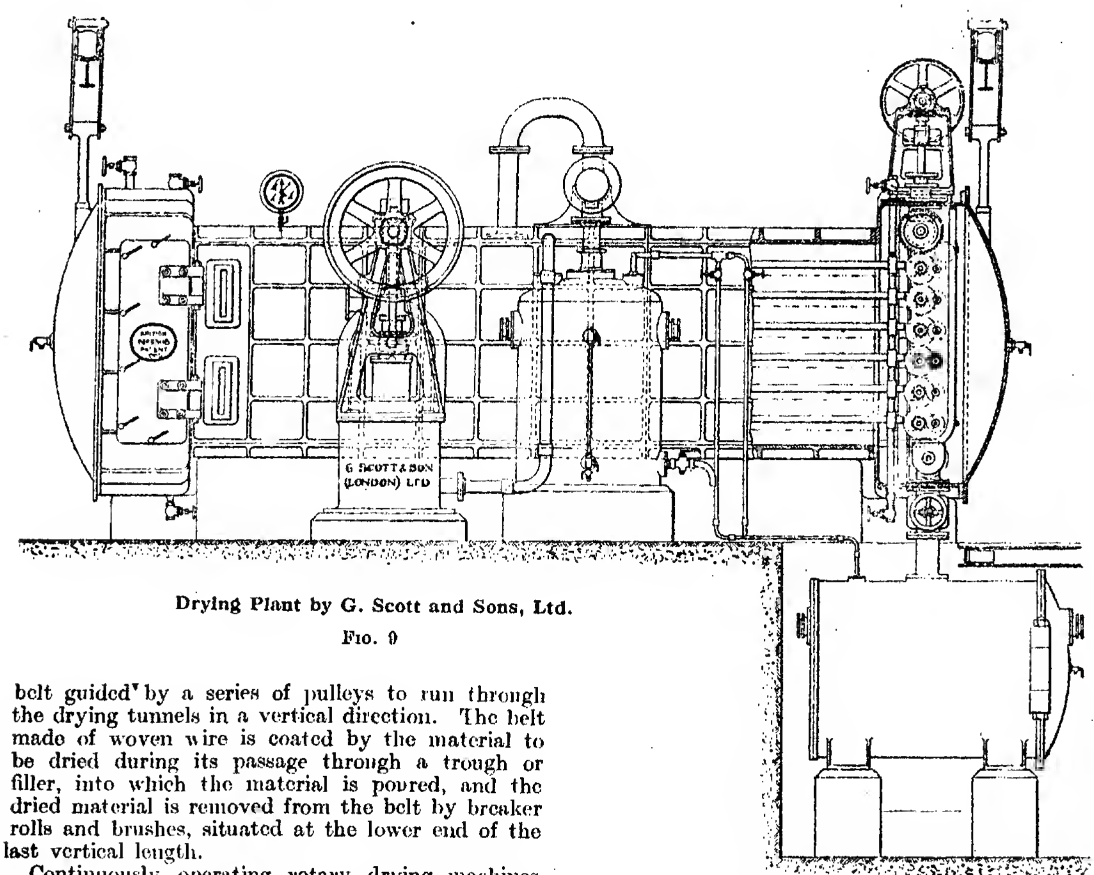


Drying Plant by G. Scott and Sons, Ltd.
FIG. 8

through a number of parallel tubes which are heated externally by steam. The next figure (9) illustrates a drying plant suitable for dealing with liquids. In this case the liquid is fed on to each of a number of parallel belts, which pass over a series of heating shelves, one belt encircling each shelf. After drying, the material is removed from the belt by a suitably placed scraper. The belts may be made of a fine mesh wire screen, coated with a gelatinous substance, and the material may be spread thereon either by rollers or as a fine spray. So far the machines described have horizontal belts, but machines have been designed consisting of one long belt guided by a series of pulleys to run through the drying tunnels in a vertical direction. The belt made of woven wire is coated by the material to be dried during its passage through a trough or filler, into which the material is poured, and the dried material is removed from the belt by breaker rolls and brushes, situated at the lower end of the last vertical length.

Continuously operating rotary drying machines are manufactured by Manlove, Alliott, & Co., Lennox Foundry, and other firms. They consist of a long hollow cylinder, usually made of mild steel and having its axis placed at a slight inclination to the horizontal. On the outer surface of the cylinder, near the ends, are mounted cast-iron path rings or tyres which rest on anti-friction rollers. In very long cylinders path rings and rollers are fitted at intermediate points in the length. Rotation is produced through a toothed wheel also fastened to the outer surface of the cylindrical shell. Radial shelves are sometimes riveted to the inner surface of the shell. If the material can be safely treated by being brought into contact with gases at temperatures between 430° C. and 490° C., the driers are generally heated by gases from a furnace. These gases may enter at the lower end of the cylinder, the material being admitted at the upper end, thus giving counter flow.

Whilst this arrangement is economical from the point of view of heat exchange, it is sometimes found unsuitable in practice, because some of the vapour in the saturated gases leaving the drier, on coming into contact with the cold material entering, may be condensed on the incoming material and convert it into a paste or cause it to form into balls, thus making drying more difficult. With this method also a considerable amount of heat is carried away by the material leaving the drier. To overcome those objections the furnace gases are sometimes admitted with the material at the upper end of the tube, a method which permits of greater control of the temperature conditions prevailing inside the tube. Sometimes the furnace is situated near the upper end of the tube and the brickwork of the furnace is arranged to envelop the tube over

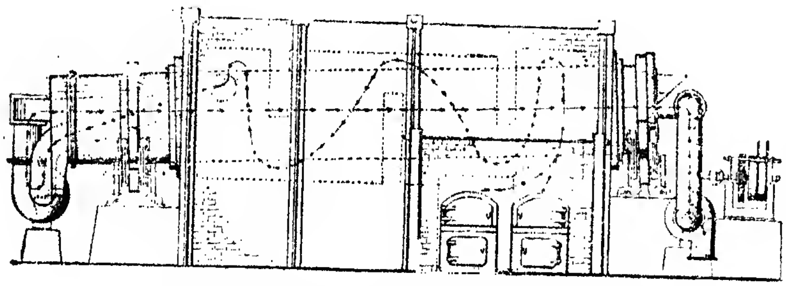


Drying Plant by G. Scott and Sons, Ltd.

FIG. 9

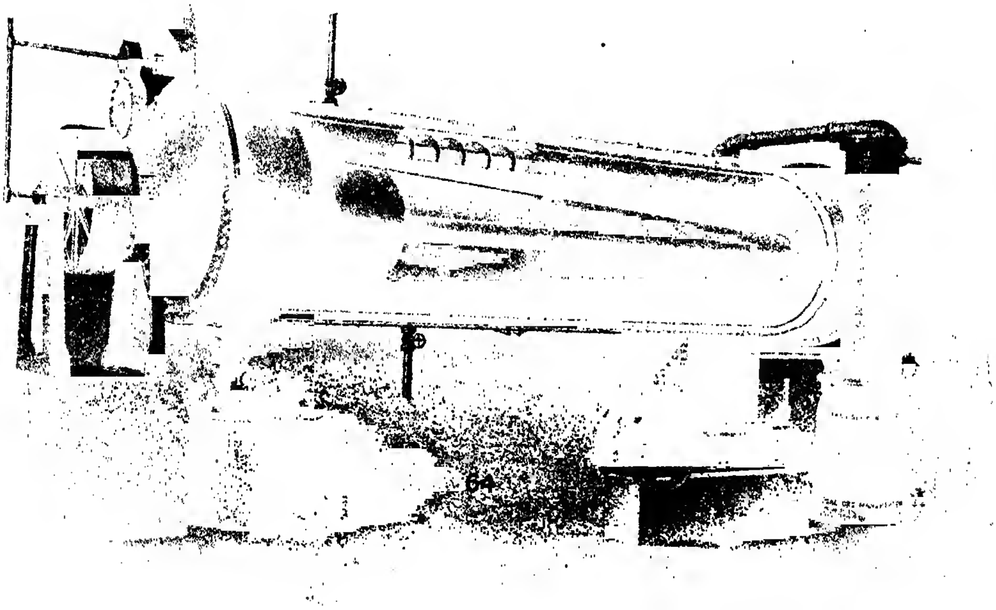
practically the whole length, as in Fig. 10. Then the hot gases from the furnace flow over the outside of the tube in the same direction as the material passing through the tube, and then entering the tube at the lower end pass over the material in the opposite direction to its flow. The brickwork surrounding the tube should be constructed to form a narrow annulus with the tube so as to create a considerable velocity in the flue gases and thus increase the rate of heat transfer. The suction required to move the hot gases through the tube may be produced by a fan or chimney, but the former is the better device since the velocity of the gases can be more easily regulated and their exit temperature may be considerably below that required to produce the draught when a chimney is adopted. A by-pass should be provided to prevent the hot gases passing round or through the tube when the drier is not in use.

Whenever the material is liable to injury from excessive heating or where its moisture content is low, rotary drying machines are generally heated by steam, and four types of heating systems are employed. In the first type the air is heated in a separate chamber and then admitted to the tube, whilst in the second type the heating element, generally in the form of a hollow cylinder, is placed inside the tube. Sometimes the tube itself is heated by means of a steam jacket, and in



Fire-heated Rotary Drier by Manlove, Alliott and Co., Ltd.

FIG. 10



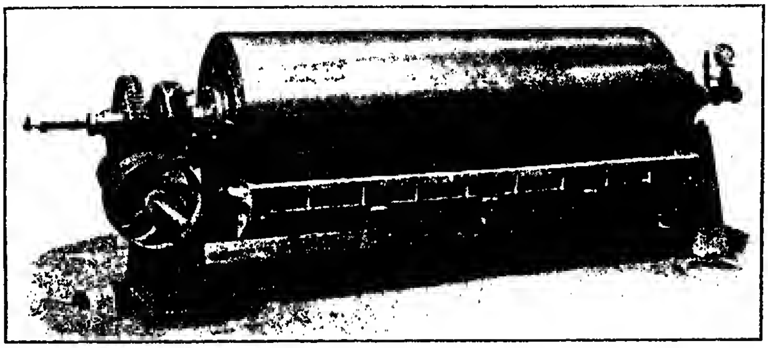
Vacuum Continuous Cone Drier by F. Shaw and Co., Ltd.

FIG. 11

this case the material being dried receives heat from the walls of the tube by conduction and radiation. A drier manufactured by F. Shaw and Co., shown in Fig. 11, illustrates the fourth type, which is really a combination of types two and three. Inside a steam-jacketed cylinder, which in this case remains stationary, is placed a hollow shaft which extends through the covers of the cylinder and can be rotated by a suitable driving gear. Attached to this shaft and mounted concentrically with it is a conical tube made of light sheet steel. The material is fed into the machine at the top left hand corner of the outer casing, by means of a specially designed rotary device which is vacuum tight, and is then transferred by a worm conveyor to the other end of the cylinder where it falls into a chute which discharges it into the narrow end of the conical tube. Steam is admitted to the outer jacket and the hollow shaft, both of which are provided with suitable drainage devices for the removal of the condensate. The plant is designed to withstand considerable steam pressure in the jacket and tube, whilst a high degree of vacuum is maintained within the cylinder. Plants of this type are also made in which the inner and outer-heating elements revolve together. Sometimes the term rotary drier is confined to plant having a stationary casing and an internal heating element which rotates, the name revolving drier being used to denote a plant with a rotating outer tube. The working temperatures of steam heated driers of this type generally vary between 50° C. and 100° C.

The drum type of drier consists of a hollow cylinder mounted with its axis horizontal. Steam is admitted to the drum through one of the trunnions and the condensate is removed through the other. The liquid to be dried is applied to the outer surface of the drum as a thin film and after drying is removed by scrapers or knives. The commonest method of applying the liquid is to make the drum dip into a shallow tray containing the liquid. With this method, however, there is always the possibility of heating the liquid in the tray and if the plant is working under a high vacuum the resulting evaporation may cause the liquid to become so concentrated that a proper film is not obtained on the roll, and with some liquids precautions have to be taken against settlement in the tray. To obviate these difficulties the liquid is sometimes sprayed on to the surface of the roll, but this necessitates the installation of pumping plant for the spray and, as can be easily understood, difficulties may be encountered at the nozzles. Complete removal of the dried material is necessary for efficient working of plants of this type.

Figure 12 illustrates a drum drier in which careful attention has been given to the feeding so as to produce a uniform film over the surface of the drum. In this plant several small knives are used to remove the material. These knives overlap one another and thus ensure complete removal of the dried material from the drum. On leaving the knives the material falls into a trough and is then conveyed to one or other of the receiving boxes placed at the ends of the plant. The worm is operated in such a manner that each box is filled alternately. Inspection ports are provided so that the working of the machine is under thorough observation. Kestner's also manufacture a non-vacuum type of drum drier, and it has been found that owing to the short time the material is in contact with the roll, this type of plant can be used for drying delicate materials. The other illustration Fig. 13, shows a double drum drier made by J. P. Devine. In this type of drier the material is fed into the space above and between the drums. From this point it is spread uniformly over the surfaces of the drums. The drums themselves are mounted in such a manner that the distance between the surface of the drums can be varied. By this means the thickness of film on the drum can be altered to ensure the material being properly dried when it is removed by the knives. Any material which is not taken up by the drums is collected in a trough placed underneath and can be returned to the feed hopper. After being removed by the knives the material drops into suitably placed receivers.



Drum Drier by the Kestner Evaporating and Engineering Co., Ltd.

FIG. 12

The double drum drier is suitable for dealing with pastes and materials which only adhere to the drum surfaces when applied under pressure. In machines of this type the drums usually rotate from one to four revolutions per minute and with properly designed bearings require very little driving power. Blair, Campbell and McLean also manufacture a rotary twin drum atmospheric drier which is used for drying milk and other products. Driers of the drum type can also be used for drying materials like paper. In this case the drier consists of a number of drums over which the paper is passed in such a manner that each surface of the paper comes alternately into contact with the drum surfaces.

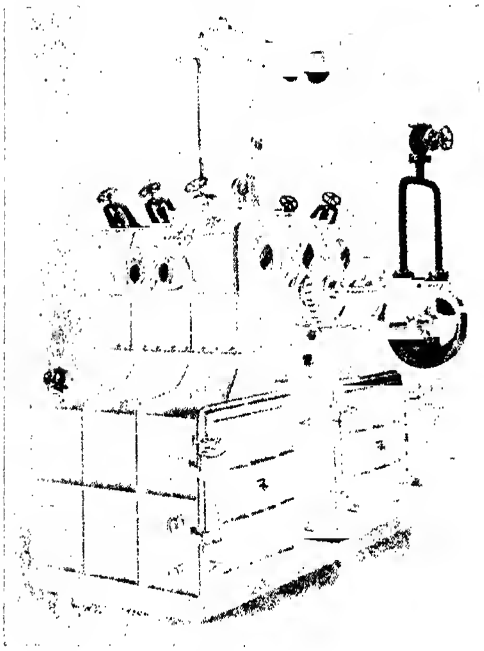


FIG. 13

Devine double-drum vacuum dryer

In spray driers the material to be dried is blown in the form of a fine spray into a chamber through which passes a current of hot air. The hot air takes up the moisture from the spray and the dried material can be separated from the moisture-laden air in a cyclone.

Acknowledgment must be made of the kindness of the various plant manufacturers mentioned in the article in supplying information and in courteously permitting the use of illustrations.

Prof. H. Carmichael, late professor of chemistry in Bowdoin College, Montana, died on January 29, aged 77.

THE REMOVAL OF CARBON BISULPHIDE BY A NICKEL CATALYST

In a paper of recent date read before the Royal Society, E. V. Evans and H. Stanier deal with some interesting chemical aspects of the so-called Carpenter-Evans catalytic process in which carbon bisulphide is removed from coal gas by hydrogenation in contact with metallic nickel. The anomalous behaviour of the nickel catalyst in resisting the poisonous action of sulphur compounds receives especial attention. From a consideration of the conditions of equilibrium in the system hydrogen-hydrogen sulphide in contact with nickel at the working temperature of the process, it is concluded that the concentration of sulphur in the gas is such that practically complete sulphidation of the catalyst must take place and this is verified by experimental observations. It is shown that nickel sulphide, whether obtained from the oxide or by precipitation, is quite a satisfactory substitute for the metal although, in the case of the sulphide, an initial period of reduction is to be observed during which the catalyst does not properly fulfil its function. A study of the reduction of the precipitated sulphide in hydrogen under the temperature conditions of the process discloses the fact that the reduction takes place in two distinct stages, first very rapidly to a lower sulphide and finally exceedingly slowly to metallic nickel. The lower sulphide is proved to have the composition represented by the formula Ni_3S_2 and appears to be the compound discovered by Bornmann in a cryoscopic examination of a nickel-sulphur melt. The authors conclude that it is this subsulphide which is the true catalyst in the process no matter whether nickel or the normal sulphide is initially used.

A section of the paper is devoted to a study of the velocity of the interaction in so far as it is affected by temperature and promoter action. A very appreciable increase in the rate of change is affected by addition to the nickel of various oxides such as thoria, alumina, chromium oxide and beryllium oxide. Thoria produces the maximum effect and the activity of a mixture of this oxide with nickel sulphide is compared at different temperatures with that of nickel sulphide only. It is shown that the thoria mixture gives the optimum acceleration at 350° C. at which temperature the speed of the interaction is about doubled whilst it is interesting to note that, at a given speed of change, the mixture can be used at a temperature 40° lower than the sulphide alone.

The function of the nickel subsulphide in the reaction is discussed and it is shown that normal nickel sulphide is one of the products of change. Further the speed of the reaction is shown to approximate very closely to that of the reduction of the normal sulphide present, and thus the rate of regeneration of Ni_3S_2 from NiS determines the velocity of the main catalytic interaction. A hypothesis is given indicating the possible nature of the reactions taking place at the surface of the catalyst.

AN INTERNATIONAL LANGUAGE FOR CHEMISTRY

By Prof. T. S. PATTERSON, D.Sc.

A remark by one of your correspondents in a recent issue of *Chemistry and Industry* prompts me to raise this subject, which I feel for several reasons to be of considerable importance, and upon which it might be of interest to elicit the views of chemists generally. Doubtless many people would advocate the adoption of English, but it is quite possible that the French and the Germans might not agree with them, and exactly the same kind of attitude would probably be taken by other nations towards French and German. It may be true that some one of the modern European languages will ultimately survive as a universal means of common expression, but it is quite certain that this could only occur after very many years of struggle between the different modern European languages, and in the end it might perhaps be simpler, and I believe that from an intellectual point of view it would probably be better, in any case, if the different nations could agree to use Latin as a universal means of communication. It would, of course, only be possible to make such a change very gradually. In the first place, Latin might be recognised as an official language. Secondly, arrangements should be made to teach it in a reasonable manner in all schools, so that in the course of some twenty years or less it would be possible to issue an international publication containing abstracts in Latin of chemical papers which had appeared in any of the other languages.

The claims of Latin to be adopted for this purpose seem to me to be as strong now as they were two hundred years ago. Most of us study at school at least three languages, and surely it seems reasonable that one of these should be a language recognised, and for the most part studied, already by all nations. If one must learn another language it would surely be better to learn Latin—largely the foundation of the English language—with its great literature and traditions behind it, and against the adoption of which there is not likely to be any international jealousy, rather than some artificial makeshift like Esperanto. If Latin, French, and English were studied in schools in one group, and their mutual interdependence insisted upon, and if, further, Latin were taught as a living language in the same kind of way that French is usually taught, these three languages should greatly help one another and make all of them much more valuable educational instruments than they are at present.

There would, I think, be three very great advantages in the universal adoption of Latin. In the first place, the interest of chemists generally could hardly fail to be awakened in that great classical literature, of which at the present time the vast majority of scientists are oblivious, and of which as a class they are constantly becoming more and more ignorant. In the second place, it is important to remember that the foundations of most of our sciences are laid in Latin, and, surely, since it cannot be said that the writings of men like Newton, Huygens, Kepler, Descartes, Stahl and others are obsolete, these fundamental works ought not to be forgotten. On these foundations we are still building, and it seems to be a very great pity at the least that so few of us are able to read these scientific classics for ourselves, since many of them do not exist in translations; even Isaac Newton's work is not yet all available in English. I certainly believe, firstly, that it would not be more difficult to adopt Latin rather than any other language, natural or artificial, as an international language for science; and, secondly, that even if it were more difficult any difficulty would be far more than compensated for by gains in other directions.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

WEDNESDAY, JULY 9.—*Morning:* Council Meeting. Annual General Meeting in the Arts Theatre, University. Presidential Address by E. Frankland Armstrong, D.Sc., F.R.S.; *Afternoon:* Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening:* Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

THURSDAY, JULY 10.—*Morning:* Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon:* Inspection of the Works. *Evening:* Annual Dinner of the Society at the Midland Adelphi Hotel.

FRIDAY, JULY 11. *Morning:* Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening:* Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

SATURDAY, JULY 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

OFFICIAL NOTICE

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

[illegible]ighth volume of these Reports is now ready, [illegible]ies have been despatched to purchasers.

[illegible]rice of the book is 7s. 6d. to members of the [illegible] and 12s. 6d. to non-members, post free in [illegible]e.

[illegible]mber of the Society may purchase a set of [illegible] to VIII inclusive at the reduced price of [illegible]d., and a Non-Member can procure a set at [illegible]uced price of £3 15s., post free in each case. [illegible]ull particulars see page ix. of the Advertisement [s]ection of this issue.

LONDON SECTION

A joint meeting with the London section of the Institute of Chemistry was held in the Institution of Mechanical Engineers, on March 31, when two cinematograph films, prepared under the auspices of the Association of British Chemical Manufacturers and entitled "Heavy Chemicals" and "Coal and its Products," were shown by permission of Mr. W. J. U. Woolcock, C.B.E. (General Manager of the Association of British Chemical Manufacturers). Dr. Bernard Dyer, who presided, called upon Mr. Woolcock to address the meeting.

Mr. Woolcock said he wished to point out what was aimed at in preparing industrial films dealing with branches of chemical industry, in order that those present might appreciate their proper value. Publicity was first begun by the man who, instead of having a blank shop window, decided to put some of his goods into it. Others followed suit, and the shop window with goods displayed in it soon became common. Following that, there was the newspaper advertisement, which carried us up to the present, but those who were really anxious for the success of any particular industry had to go one step further. Now, the industrialist could not put his goods into his shop window with any marked effect, because everybody else did the same, and he could not do very much by advertisement. No industrialist could afford not to advertise in technical journals, but that was a species of blackmail—perfectly legitimate blackmail—in which the newspapers combined to see that the man who did not advertise was regarded as peculiar, and was out of the public eye. We had, however, got past the point where the success of the individual firm, except as a unit in an industry, was a predominating factor. One hoped for the success of each unit, because if every unit was successful the whole industry flourished, but we had got to the point that, in the big public campaign, apart from the campaign which must be waged between seller and buyer, it was now essential that the public should be familiar with the value of the industry to the nation, and that we should not be so insistent that X's brand was the best, and the only brand worth having. What we wanted to do was rather to encourage the public to think that the chemical industry as a whole was something for the British public to be interested in and to take a pride in, and gradually to instil into their minds the fact that they should insist, in all things, upon having what was provided by Great Britain. It was quite possible for a man who was advertising in the ordinary way to say that he got a certain return for his advertisements in a particular newspaper, but there was something very much bigger than that, more intangible, and much more difficult to do, and that was to impress upon the whole world that anybody connected with British chemical industry was connected with an industry which was bound to succeed and which supplied finer material than any comparable industry in any other part of the globe. Hence a mass action was going on in propaganda nowadays which was quite different from anything we had had before. The same idea was being carried out at the

British Empire Exhibition. What would be seen there was the combined effort of all the chemical firms in a particular space of 40,000 sq. ft., and behind all that—behind the big industrial show, nobody's particular show, but Great Britain's always —in a space of 2500 sq. ft., would be seen what the scientific chemists of the country had done during the past 20 or 30 years. But what was meant by that? The intelligent observer walking through the hall would say: "Yes, this is British chemical industry; looks very well; result of the war effort; quite good. But will it last?" If the observer came abroad his first question would be: "Would it last?" The effect which it was desired to create on the mind of that observer was this. He would not be asked to take any notice of what the industry is to-day. He would be asked to go into the smaller hall, where he would be shown that the flow of invention in this country, and the stream of research work going on in Great Britain to-day, is an absolute guarantee that the industry will continue, and that those connected with the industry are in business to stay. The films to be shown might appear to those present, from their own particular point of view, to be child's play. But these films were intended for the public. They were intended to be shown all over Great Britain, in all sorts of cinemas. They were, therefore, brought down, as one might say, to the level of the public, and he asked those present not to consider the films from their own technical point of view, but to ask themselves: "Are these the sort of films, prepared for the public and not for us, that we would wish to be shown to the public of Great Britain as representing two sections of British chemical industry?"

Mr. Carey (of the South Metropolitan Gas Co.) then presented another film, dealing with the decomposition of cyclohexane, on behalf of Mr. E. V. Evans (Chief Chemist to the South Metropolitan Gas Co.), who was unable to attend the meeting. At a recent lecture at the Royal Society of Arts, he said, Mr. Evans had wished to portray certain organic reactions, and had used the cinema for the purpose. The film was not intended for an audience of chemists, who might be rather displeased with the way in which the reactions were shown. For the purpose of the lecture for which it was used originally, it was decided, as the audience was composed of technologists engaged in the gas industry, to explain the reactions by means of the cinema without making them too complicated. The film was divided into five sections, the first dealing with the decomposition of cyclohexane to cyclohexene, the second from cyclohexane to n-hexylene, the third from n-hexylene to amylene, the fourth from cyclohexene to hexadiene, and the fifth representing the possibilities of the combination of those two diolefines (cyclohexene and hexadiene) to form tetrahydrophenylbutylene, finally, by dehydrogenation, giving naphthalene.

Prof. Gronover, director of the chemical laboratory of Altona, has been appointed director of the food-testing station of Karlsruhe.

LIVERPOOL SECTION

The annual meeting was held on April 4, Mr. Alfred Smetham in the chair. The following officers were re-elected for the coming Session:—Chairman, Mr. Edwin Thompson; Vice-Chairman, Dr. G. C. Clayton, M.P.; Hon. Treasurer, Dr. Alfred Holt; Hon. Secretary, Mr. E. Gabriel Jones. Prof. C. O. Bannister was elected representative on the Chemical Engineering Group and the following were chosen to fill the vacancies on the Committee:—Dr. E. F. Armstrong, F.R.S., Prof. I. M. Heilbron, Mr. W. Mansbridge, Associate-Professor W. H. Roberts, and Dr. R. Thomas.

A Paper was read by Mr. E. H. Rideout on "Agriculture and Chemical Industry: Some suggestions for increased co-operation between Chemical Manufacturers and Farmers."

The lecturer first dealt with his subject from the point of view of sales and stated that a modern sales campaign demands first the determination of the particular class of person to whom the goods are to appeal, and secondly the fixing of definite geographical boundaries to the district containing these customers. The fertiliser manufacturer is particularly concerned with the farmer, whose peculiarities distinguish him quite clearly from other men. Advertisements must be short, attractive, and well chosen, as the farmer is easily impressed but by nature cautious. The great secret of successful dealings with the farmer is to emphasise the personal nature of the transactions; and each peculiar problem needs careful study. A successful first sale is important, and every care should therefore be taken to secure the application of the correct fertiliser under appropriate conditions of soil and crop. Lime is the most important factor. All fertilisers depend for their successful action on its presence, but some, for example sulphate of ammonia and superphosphate, depend upon it in quantity. Hence if lime is deficient the land must be limed and where possible other fertilisers substituted. Both here and abroad firms are slowly realising the value of lime tests as an aid to sales. A laboratory properly equipped for soil tests, a good technical staff, and an information bureau should be regarded as essential to any sales scheme. Zoning of suitable districts can be readily carried out, if the geology and climatic factors be considered.

Feeding stuffs can and should be sold in a similar manner. It is not difficult to imagine in the future the complete defeat of the unscrupulous manufacturer and his agents by such open methods of trading. For it is particularly important that a customer once obtained should be retained, so that a bond of interest can be set up between the farmer and the manufacturer to their mutual and lasting advantage.

A meeting was held on March 21, Mr. Alfred Smetham in the Chair, in the absence, through illness, of the Chairman of the Section and an address was delivered by Associate-Professor W. H. Roberts, entitled "Some Aspects of a City Analyst's Work."

The lecturer discussed in some detail the various classes of analyses which the Public Analyst of a

large city is called upon to undertake. These included the analysis of foods and drugs, fertilisers and feeding-stuffs, water, paints, oils, varnishes, steels, non-ferrous alloys, india-rubber hose, and many other materials used by the various Departments of the Corporation; investigations required in connexion with Coroners' inquests and for the purposes of evidence in criminal prosecutions. At the present day the analysis of foods was not merely a matter of routine testing but frequently necessitated laborious investigations, particularly when new food stuffs appeared on the market. The question of preservatives in foods was treated at length and the various arguments advanced for and against their use were discussed. The lecturer said he had been impressed in the course of some investigations by the marked poisonous effects of borax on plant life. He condemned the indiscriminate use of preservatives and suggested that the time had arrived when more stringent regulations should be made to prohibit or restrict their use. The possible danger of metallic poisons arising from the greatly increased use of tinned foods was mentioned, and the lecturer finally gave some interesting details of several criminal cases in which he had been engaged.

SOUTH WALES SECTION

At the meeting in the Technical College, Cardiff, on March 7, Mr. E. A. Rudge, B.Sc., read a paper on "Metal Colouring," Mr. W. R. Bird being in the chair.

Recent developments in metal colouring processes had been quite extensive. The functions of such processes were (*a*) to produce by artificial means surface colours on metals to give an artistic appearance, or to simulate an antique appearance, and (*b*) to give a coating to the metal which would be resistant to corrosion. The methods involved could roughly be classified as processes :—(1) Involving the oxidation (or formation of sulphide) of the metallic surface; (2) involving the precipitation of one metal on another, either by simple immersion, or by electrolysis, or by forming a metallic couple in the solution; (3) comprising both (1) and (2) above; (4) for coating produced by chemical methods; (5) comprising mechanical devices, such as tinted celluloid, gelatin films, painting, enamelling and engraving.

The lecturer then discussed examples of these types of process and demonstrated the methods of production of colours by each class of process. As examples of oxidation processes, he mentioned the colouring of iron and steel by heating in air between 220°—300° C.; the oxidation of copper and brass and similar alloys by heating in solutions of perchlorates or alkaline persulphates, which gave beautiful bronze effects; the anodic oxidation (bronzing) of brass by electrolysis in an alkaline carbonate bath; the sulphiding (so-called oxidising) of copper and silver by exposure to sulphur vapour, by washing with ammonium sulphide or alkaline polysulphides.

The second group of "immersion" processes was then dealt with. This method of deposition, involving simultaneous equivalent solution of the less electro-positive metal, usually gives a coating lacking in coherence, and is only employed therefore in the manufacture of cheap goods, such as are produced by the coppering of iron.

The electro-deposition methods mentioned included the coating of iron and steel with copper, silver or brass. By subsequent colouring treatment by one or other of the methods previously mentioned a wide variety of commercial coloured surfaces can be produced, such as the silver-plated copper articles, with a black-shaded finish produced by sulphiding.

Under the miscellaneous methods, that of treating steel by heating in media such as rape oil or linseed oil in the presence of potassium carbonate, was mentioned, which gives a firm black coherent coating of carbon with a matt finish, which is an effective preventive of corrosion. "Black-nickelling" by cathodic deposition from a bath containing nickel thiocyanate was also dealt with. An interesting method of producing a variety of iridescent tints was to be found in the immersion of the metallic article in a solution of sodium lead thiosulphate, which was then warmed to 70° C. A coherent layer of lead sulphide is deposited on the surface, a wide range of colours being obtainable.

Of the mechanical devices, the one of chief interest is the application of solutions of gelatin or of celluloid suitably tinted with dyes, for colouring tinplate, photo frames, and the like.

An interesting discussion followed, during which Mr. H. J. Bailey raised the question as to the possible formation of surface alloys in some cases of metal deposition.

The annual general meeting was held on March 28. After the conclusion of the formal business, during which Mr. W. R. Bird was elected Chairman for the ensuing session, and Mr. Clarence A. Seyler, F.I.C., Vice-Chairman, Capt. Hugh Vivian, the retiring chairman, read some "Notes on the History of Copper Smelting at Swansea."

The first copper works in South Wales was established at Neath in 1584, and Swansea had its first works in or about 1724, considerable opposition being met with from farmers, owing to fears of the effects of fumes given off during smelting. In 1820 Faraday was called in to investigate the question, and from then onwards continual experiments were made in the endeavour to mitigate the nuisance. In the years 1820-22 Vivian and Sons thus spent over £13,000, a very large sum for those days. Cornish ores were at first smelted, but were gradually replaced by foreign ores, largely from South America. The extreme cheapness of coal in the earlier part of the last century had probably retarded the development of economical methods of smelting; for example, as early as 1844 a patent was taken out embodying the principle of preheating the air in reverberatory calcining furnaces and mixing it with the furnace gases at the bridge; but the method was abandoned after a few years, the cost of installation and repairs probably being too great.

About 1840 silver was extracted from South American ores by amalgamation with mercury,

but in 1843 the Augustine process was introduced, in which the silver was chloridised by roasting with salt, most of the sulphur having been driven off by a previous roasting. The process was not entirely successful, and in 1845 the Ziervogel process was introduced. In 1850 the extraction of gold from copper was commenced; and in 1895 electrolytic methods of copper refining were introduced. At a later date the slimes from the electrolysis were worked for extraction of platinum and palladium, besides silver and gold. Copper smelting in this country was now a dying industry, due to economic conditions changing, but the working up of various copper-bearing materials still went on, and, of course, the manufacture of copper sheets, tubes and rods.

Mr. Bird proposed a hearty vote of thanks to Capt. Vivian for his paper, and for his services as chairman during the session. The motion, seconded by Mr. Green and supported by Mr. H. J. Bailey, was carried with acclamation.

BIRMINGHAM AND MIDLAND SECTION

A meeting was held jointly with the Chemical Engineering Group at Birmingham on April 4, Dr. E. B. Maxted presiding. There was a representative attendance, and members of the Chemical Engineering Group were present from various parts of the country. Prior to the meeting the members visited Bournville, where, by invitation of Messrs. Cadbury Bros., they inspected the works, and some of the special machinery, and later partook of tea. A dinner followed the meeting.

Professor G. T. Morgan, F.R.S., and Dr. J. D. Main Smith gave a contribution on "The Separation of Cobalt from Nickel-ferrous Ores by the Purpureo-Cobalt Chloride Process."

In a paper on "Emulsifying Mills," Capt. F. J. China described the Premier and other disintegrating mills and their applications to industry. Considerable attention had been devoted to obtaining machinery, by means of which certain materials could be obtained in a very much finer state of division than was obtainable by ordinary grinding machinery. The Premier mill was of the type in which a film of liquid was subjected to a shearing action at very high speed. It consisted of a cone which rotated in very close proximity to a conical seating. An outer case surrounded the rotor which consisted of a perfectly smooth steel cone machined to extremely fine limits, and fixed to a spindle mounted in special bearings. This cone worked in close relation to a fixed surface which formed part of the casing, the arrangement being very similar to the action of the clutch on a motor car, except that the two surfaces did not touch. The working surface of the rotor was arranged so that there was a fine clearance between it and the surface of the casing. With this arrangement a metal surface rotated very closely to a fixed surface at a speed which might vary between 1000 and 5000 revolutions per minute. The rotor acted largely as a centrifugal pump and assisted by drawing the material between the working surfaces. It then passed through a narrow space between the conical surfaces in a fine film and, owing to the enormous speed of the rotor, the particles of solids suspended in the film are rapidly torn apart. The mill was claimed to ensure the perfect emulsification of liquids and the intensive mixing of liquids and solids and the blending of differently miscible constituents in various proportions.

Dr. E. B. Maxted thought progress might be made by means of the mill in the domain of liquid fuel. Prof. J. W. Hinchley said the colloid mill might be most useful in various directions, though he thought its scope must be rather limited at present. Mr. Barnes (Manchester) said these high-speed mills were of great use, economically, when dealing with materials ground in water. For the time being, he believed their scope in the paint trade must be confined principally to the cheaper grades of paint.

GLASGOW SECTION

The annual business meeting was held in Ferguson and Forrester's Restaurant, Glasgow, on April 3, Mr. W. E. Moodie in the chair. Dr. J. A. Cranston read the honorary local secretary's report, which was duly adopted. The report of the representative of the Section, Mr. D. A. MacCallum, to the Glasgow Chamber of Commerce, was read and approved. It was emphasised that the Glasgow Section was discharging a good office towards chemical industry in being represented on the directorate of the Glasgow Chamber of Commerce.

The following members were elected to fill the vacancies on the local Committee:—Mr. D. A. MacCallum, Chairman; Mr. W. E. Moodie, Vice-Chairman; Dr. J. A. Cranston, Hon. Secretary; Messrs. C. Chapman, J. Robertson, R. F. Stewart, and J. F. Young, Members of Committee. On the call of the chairman, votes of thanks were accorded to the retiring members of committee, and to Prof. R. M. Caven for reporting the meetings during the session to the local press. The retiring chairman was then, on the motion of Mr. S. B. Langlands, accorded a hearty vote of thanks for his services during the past two years.

Following the business meeting a joint smoking concert was held with the local section of the Institute of Chemistry.

PATENTS IN ESTHONIA

Owing to the accession of the Republic of Esthonia to the International Convention for the Protection of Industrial Property, an Order in Council was made on February 20, 1924, applying the provisions of Section 91 of the Patents and Designs Act, 1907, as amended by the Patents and Designs Act, 1914, and the Patents and Designs Act, 1919, to the Republic of Esthonia as from February 12, 1924. A copy of the Order may be seen in the Patent Office Library, 25, Southampton Buildings, London, W.C. 2. (*Official.*)

CHEMICAL SOCIETY

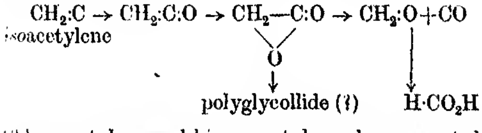
At an ordinary meeting, held on Thursday, April 3, the president, Prof. W. P. Wynne, who occupied the chair, announced that the council had accepted with regret the resignation of the senior secretary, Prof. J. I. O. Masson, who was shortly leaving London; a resolution had been adopted which put on record their appreciation of the value of his services to the society. Dr. T. Slater Price had been nominated by the council to act as senior secretary until the next general meeting. In announcing the composition for the ensuing year of the Finance, House, Library, Publication and Research Fund Committees, the president paid tribute to the services rendered by the retiring chairman of the Library Committee, Prof. J. M. Thomson, who would be succeeded in that office by Prof. J. R. Partington.

The Research Fund Committee would, he announced, meet early in June; applications for grants must be made before June 2.

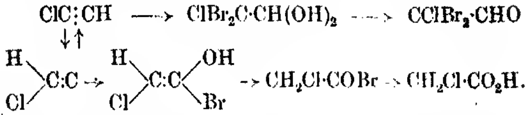
Mrs. E. H. Ingold discussed:

The tautomerism of dyads. Part II. Acetylene and its halogen derivatives.

The suggestion (*Chem. and Ind.*, 1923, **42**, 1247) that acetylene, although consisting mainly of CH⋮CH, is in equilibrium with a minute amount of *iso*acetylene, $C{:}CH_2$, has now been experimentally verified in two ways. In the first place the specific heat of acetylene has been shown to vary with temperature in such a way as to indicate the existence of a mobile equilibrium similar to that shown to be present in hydrocyanic acid, where H·C⋮N is in equilibrium with a little H·N:C. Secondly, chemical evidence of the existence of detectable quantities of *iso*acetylene at moderate temperatures has been obtained by a study of the mechanism of oxidation. The first product, previous even to formaldehyde (Bone and Andrew), is keten $CH_2{=}CO$, which is the normal oxygen addition product of *iso*acetylene $CH_2{=}C$, just as *iso*cyanates R·N=C=O are the normal first products from isonitriles, R·N=C. It is possible that the low-temperature oxidation of acetylene takes place mainly through the *iso*acetylene form, since Bone and Andrew's results receive ready interpretation on this basis:—



Chloroacetylene and bromoacetylene also appear to be tautomeric substances of a similar character, and not, as Nef supposed, purely *iso*acetylene (acetylidene) derivatives. Thus chloroacetylene polymerises under the action of light to *s*-trichlorobenzene (evidence for HC⋮CCl), whilst with iodine it yields the compound $I_2C{:}C{<}^{Cl}_{H}$ (evidence for $C{:}C{<}^{Cl}_{H}$), and with hypobromous acid it gives both chloroacetic acid and chlorodibromoacetaldehyde (evidence for both structures):—



Further confirmation of the mobility of these substances is provided by the properties of the static dihalogeno*iso*acetylenes. Like all bodies of this kind, the tendency to acquire the hydrogen atom necessary for tautomerism is so great that spontaneous reduction will occur. This is true of the static substance $CBr_2{:}C$ (Laurie), which is spontaneously reduced to the monobromo-compound in the presence of alkalis, and so readily does the same reaction take place with $CCl_2{:}C$ that all attempts to prepare this compound resulted in the isolation of the tautomeric monochloro-derivative.

Prof. E. C. C. Baly doubted whether, on the energy quantum theory, it was necessary or desirable to postulate the existence of tautomeric equilibria. He asked how the author was able to recognise the scarce isomeride by treatment with hydrogen bromide.

Dr. T. Slater Price, recalling the fact that hydrogen cyanide in quantity has an unpleasant odour reminiscent of that of *iso*nitriles, asked whether the fact that the halogeno-derivatives of acetylene, in contrast with the parent hydrocarbon, possessed unpleasant odours might indicate a greater prevalence of the *iso*-form.

Dr. R. H. Pickard congratulated the author on her work, but queried the use of the term "dyad" in this connexion.

Prof. C. K. Ingold said that thermodynamics could not decide the structure of the more highly energised form; collateral evidence was required for that. Quantic energy distribution and the co-existence of molecules having many grades of energy applied to gases possessing normal specific heat values as well as to abnormal substances like hydrogen cyanide, acetylene, and probably also formaldehyde, the energised form of which was regarded by Prof. Baly as that with bivalent carbon. The relative ease of spontaneous reduction of the dihalogenoacetylenes was in conflict with Macbeth's polar theory of this reaction, and provided an offset against the case of the dihalogenodinitromethanes recently quoted in support by Gotts and Hunter.

Mrs. Ingold, replying, pointed out that chemical evidence of the existence of the *iso*-form was obtained only in the case of the halogenoacetylenes which must have much longer *iso*-phases than is the case with acetylene itself. Doubtless the greater stability of the *iso*-phases accounted for the pronounced odour and physiological action of the halogen derivatives as compared with the hydrocarbon, as well as the enhanced reactivity of the former. The nomenclature "dyad" and "triad" as applied to tautomeric systems was introduced by Laar.

Prof. H. Bassett described experiments on:

The potassium salts of phenolphthalein.

A PHASE rule study of the system phenolphthalein—potassium hydroxide—water at 25° has shown that the conditions which prevail are very similar to those found in the analogous system containing sodium hydroxide (Bassett and Halton, *J. Chem. Soc.*, 1923, **123**, 1291). Although a number of hydrated forms of the mono-, di-, and tri-potassium salts of phenolphthalein can separate from aqueous solutions at 25°, they are all colourless. The behaviour of the tripotassium salt on heating to 150° suggests that a solid red salt is formed by elimination of one or two molecules of potassium hydroxide. No method of obtaining a pure red salt was found.

Prof. H. Bassett also read a paper on:

The hydrolysis of potassium ferricyanide and potassium cobalticyanide by sulphuric acid.

POTASSIUM ferricyanide was hydrolysed by sulphuric acid of varying concentrations, and the different products of hydrolysis were determined. With concentrated sulphuric acid, ferrous sulphate and carbon dioxide were obtained, a fact previously unnoticed, and the reaction could be represented by the equation:—

$$2K_3Fe(CN)_6+11H_2SO_4+13H_2O=3K_2SO_4+6(NH_4)_2SO_4+2FeSO_4+11CO+CO_2.$$

With more dilute acid the reaction followed the course indicated by the equation:—

$$2K_3Fe(CN)_6+6H_2SO_4=3K_2SO_4+Fe_2(SO_4)_3+12HCN.$$

The hydrolysis of potassium cobalticyanide by concentrated sulphuric acid was analogous to that of potassium ferricyanide, and could be represented by a precisely similar equation. With more dilute acid, hydrocyanic acid was obtained as in the case of ferricyanide, but the hydrolysis was slow owing to the greater stability of the cobalticyanide. By long digestion under a reflux the amount of hydrocyanic acid obtained with dilute acid was that required by the equation:—

$$2K_3Co(CN)_6+6H_2SO_4+2H_2O=3K_2SO_4+2CoSO_4+(NH_4)HSO_4+11HCN+CO_2.$$

A white compound of cobalt which appeared as an intermediate product of hydrolysis with dilute acid, was separated, whilst a white complex cobalticyanide was also obtained by the action of bromine on potassium cobalticyanide in aqueous solution. These substances appeared to be potassium aquopentacyanocobaltiates, analogous to the corresponding ferricyanide derivatives prepared by Briggs (*J. Chem. Soc.*, 1920, **117**, 1026), but they were not fully investigated.

Prof. J. C. Philip recalled an observation made in his laboratory by Dr. A. Bramley that in the case of solutions of ferric thiocyanate, spontaneous reduction to ferrous iron was accompanied by oxidation of the carbon to carbon dioxide.

Dr. N. V. Sidgwick instanced the removal of the residual colour of alkaline cuprous solutions by the action of carbon monoxide.

Prof. Bassett's final paper was entitled:

A study of the cupro-, argento-, auro- and thallo-cyanides of potassium according to the phase rule.

THE paper gives an account of a phase rule investigation (at 25°) of the four systems KCN, H_2O and CuCN, AgCN, AuCN or TlCN. In the case of the cuprous cyanide system the salts $K_3Cu(CN)_4$, $K_3Cu(CN)_4,H_2O$, $KCu(CN)_2$ and $KCu_2(CN)_3,H_2O$ were found to exist. Of these all except $K_3Cu(CN)_4,H_2O$ were previously known. Three potassium argentocyanides were obtained, viz., the well-known compound $KAg(CN)_2$ and two new ones $K_3Ag(CN)_4,H_2O$ and $KAg_2(CN)_3,H_2O$. The conditions under which the latter can be formed are very restricted. The bearing of the results obtained on Liebig's volumetric method for determining cyanides is discussed. Only one aurocyanide $KAu(CN)_2$ was obtained. In the case of thallium, a thallocyanide $KTl(CN)_2$ was found to exist, although it is stable in contact with solutions over only a very small range of concentrations. This compound is of interest because it contains univalent thallium in the anion.

Dr. N. V. Sidgwick, commenting on the author's triangular diagrams, remarked that the vertical solubility line was not fortuitous, but would be expected if there were complete formation of the compound $KAg(CN_2)$ from the insoluble cyanide.

Dr. T. Slater Price said he was interested to observe that the author had isolated salts of the existence of which he had some years ago obtained electrometric indications.

Prof. Bassett, replying to Dr. Sidgwick, said that one might expect to find the compound $KAg_2(CN)_3$ in solution as well, coming, as it did, intermediately between $KAg(CN)_2$ and AgCN. It was also interesting to note that he was unable to obtain the compound $K_3Ag(CN)_4$, the monohydrate always being produced.

SOCIETY OF GLASS TECHNOLOGY

The president, Prof. W. E. S. Turner, presided at the meeting held in Stourbridge on March 19.

The first paper dealt with the "Properties of lead-containing glasses." Prof. Turner, who communicated this paper, described the special properties of the alkali-lead oxide glasses, with particular reference to their thermal expansion, chemical durability and electrical properties.

Mr. J. Northwood followed with a paper entitled, "The Art of British Glass Decorators—The Duplication of the Portland Vase." The Portland Vase, he said, was regarded as the greatest achievement of the ancient glass-makers. The vase is composed of two glasses, the inner body or groundwork being of a very dark blue transparent glass, and the outer casing of white opal glass out of which the ornament and figures are sculptured. This decoration stands up in relief from the blue ground. The reproduction of the Portland Vase was accomplished by the late John Northwood, with the aid of his relative, Philip Pargeter. The casing of the blue body with a uniform outer layer of opaque white was considered at that time as a matter requiring great skill on the

part of the glass maker. It was believed that the actual maker of the glass used in this English Portland Vase was Daniel Hancock, of Wordsley. The work was begun in 1873. The exterior opaque white was slightly acted on by hydrofluoric acid, and the design drawn upon it. Then commenced the hard labour of removing the surplus white glass from round the figures and design, right down to the blue body-ground. Extreme care and patience were necessary to chisel out, without mishap, the delicate details in order to create a true reproduction. The vase was very nearly completed when it suddenly cracked, owing probably to a difference in coefficients of expansion of the two glasses. Still, the artist was not discouraged, and in 1876 the work was completed. The vase is now in the collection of Mr. P. Pargeter, of Stourbridge.

ACADÉMIE DES SCIENCES

On March 3 Prof. Moureu described his researches with Monsieur Dufraisse on the theory of catalytic auto-oxidation. Iodine and its compounds have been found to play an important part in oxidation by free oxygen. Thus a trace of iodine prevents any auto-oxidation of benzoic aldehyde whilst strongly accelerating the auto-oxidation of styrolene.

Monsieur Richet described work on the action of insulin on hyperglycæmia due to caffein. Prof. Lindet drew attention to a new class of micro-organisms discovered by Monsieur Guitoneau, and called by him micro-siphonaceœ, which reproduced many soil reactions such as the digestion of nitrogenous matter, and possibly the absorption of atmospheric nitrogen.

Monsieur Le Chatelier discussed the absorptive power of cuprous sulphate for carbon monoxide, a reaction which should be useful in analytical work, and which may prove useful industrially, as thanks to it, it becomes possible completely to eliminate carbon monoxide when making hydrogen from water gas.

On March 10, Monsieur Le Chatelier communicated a note by Monsieur Charrioux on a new process for the electrolytic purification of colloidal precipitates. The process, which gives good results with a colloidal suspension of alumina, cannot be applied to crystalline precipitates.

Monsieur A. Desgrez was elected a member of the Section of Free Academicians. Monsieur Desgrez, who has been general secretary of the French Association for the Advancement of Science for many years, and has organised many of that body's annual meetings, is a chemist whose researches have always had a biological and medical bent such as cancer and diabetes. To him was due the solution of the problem of regenerating vitiated air by means of sodium peroxide, and during the recent war he did valuable service in the work of protection against poison gases.

On March 17, the Académie heard the funeral oration of Count Chardonnet (*cf. Chem. & Ind.* March 28, 1924). Prof. Moureu described researches carried out at the University of Copenhagen on methods of estimating bismuth in the organism, utilising radioactive phenomena.

CORRESPONDENCE

CHEMISTS AND THE PUBLIC

Sir,—May I beg space to comment upon your recent Editorials in which you touch upon the question of the Chemical Societies.

Your remark, "If chemists wish to make an impression on the public they should abandon the practice of reading papers to each other . . .," seems very pertinent. And at the risk of appearing to indulge in cheap wit, I should like to supplement your words of wisdom by suggesting that it should be regarded as a breach of professional etiquette for a chemist to address a gathering of chemists, except on very special occasions. Let his addresses be confined to audiences of laymen, and let them be in a popular style.

Academic chemists, who are accustomed to speaking, and those technicists who are gifted in that line, would do far more good by public lecturing than by attending meetings of their fellow chemists and reading papers. Some sort of local club would afford the necessary opportunities for meeting one another. I have vivid recollections of a club run by the English-speaking colony in a small German town. We met there on Saturday nights; and social contact was assisted by a piano and card tables, with a small cask of beer as a catalyst; quite a small cask.

It appears to me that the study and practice of chemistry is in danger of being degraded to the level of a hobby. We have societies and associations for model engineers, pigeon and rabbit fanciers, philatelists and countless others. The members are enthusiasts in a particular subject and meet to discuss it. Their influence on public opinion is nil.

By continually addressing his fellow members a chemist advances himself within the limited range of a profession which is scarcely recognised as such by the general public. If the profession happened to be widely recognised, respected and exercising a powerful influence, such means of advancement within it would be excusable. But when the contrary is the case, it seems a waste of time. The most important parts of these addresses are usually printed, and can then be much more easily digested by their fellow chemists.

What the profession of chemistry needs is propaganda work. This may go against the grain in many cases, but without it there seems little to hope for. Reach the man in the street or adopt some other profession—bricklaying, fitting, plumbing or coal mining—these at least are essential trades and are recognised as such.

May I suggest that chemists cut out one of their subscriptions to journals—many of us take out more than are strictly necessary—and turn over the money to the support of some organisation devoted entirely to propaganda work. Something after the style of the *Children's Newspaper*, but with a wider range of appeal, might be useful. Say, one-third devoted to racing and football, one-third to news, and the remainder to general scientific information, reports of new discoveries,

and especially to emphasising the important part played by science in the life of the nation.

It may seem degrading to drag the bright flame of scientific enthusiasm through the gutter—I hate the idea myself—but it seems the only way.

I know that great difficulties have to be surmounted before chemists can present a united front to the world. There are so many divisions and subdivisions, so much fighting and wrangling with one another, this society with that, the academic chemists with the technical, and those with degrees with those lacking degrees. And in addition to the difficulty of securing recognition from the non-educated public there is the difficulty of securing it from the educated and literary classes; the task of overcoming the mutual suspicion and thinly veiled contempt which exists between scientific and literary men, between scientific men and business men, between the new order and the old. Within the profession there is the difficulty that it contains so many of widely different social position—an almost insuperable bar to unity.

Chemists may claim that they are united. It is, I fear, only a pleasant fiction. What kind of unity is there between the higher orders of academic chemists and the newly fledged industrial chemist? Nothing like the same unity as between the eminent consulting medical and the youngest hoister of a brass plate. Nothing like that which exists between the eminent K.C. and the rawest recruit at the Bar.

I do not wish, Sir, to disparage in any way the efforts now being made by our leading chemists to cope with some of these evils; nor do I underrate the value of this journal. On the contrary, I regard the decision to publish it in a semi-popular form, as the first step in the right direction.

You have remarked upon the exasperation which some people have displayed towards elementary articles appearing in your columns. I differ from them in believing that it would be advantageous to make these even more elementary and to increase their number.

This generation can scarcely hope to feel the benefit of any reforms. But we must try to ensure that the chemists of the coming generation have a chance of occupying the position they deserve in our everyday life; and to do this it is essential that we should reach the generation of laymen now growing up. It seems much more important that the man in the street should have his eyes opened to the wonders of a paving stone, than that a chemist should lecture to a physicist or *vice versa.*

I fear, that in the exuberance of the moment, I have used expressions that savour of sarcasm. If so, I crave pardon of any who may feel inclined to take offence. Stripped of their verbiage and reduced to a common denominator of moderation, in which "is and must" are replaced by "might and may," the views expressed are perhaps not without truth. They are really only the expression of a train of thought suggested by your editorials.—I am, Sir, etc., ROBERT GILMOUR

Belfast
March 31, 1924

THE INSTITUTE OF CHEMISTRY

Sir,—I have read the letters in recent issues of *Chemistry and Industry* and your editorial note in the issue of the 28th ult.

The letters serve a useful purpose in bringing to light misconception of the regulations of the Institute on the part of your correspondents. Possibly this is the explanation of the letters, and that they have not any necessary connexion with the attitude of mind of the quadruped to which you make reference.

Neither "A Chemist" nor "An Unqualified Chemist" appears to be aware that since 1917 it has been possible for a candidate to enter the Institute by the front door and yet without further examination, provided that he has complied with certain reasonable regulations.

With regard to the criticism of public analysts, by reason of the alleged action of one or two, it may be well to remark that the Council have invariably required candidates for the examinations of the Institute to take systematic courses in properly equipped universities and colleges, and have consistently for over thirty years discouraged training in private laboratories unless, in addition, adequate provision be made for such systematic instruction.

The Council are further aware that in many private and industrial laboratories there must inevitably be a number of unqualified assistants, but they have rendered it possible for such assistants to secure the qualification of the Institute.

Pupil apprentices and assistants who really wish to qualify can attend systematic evening courses at one of the institutions recognised by the Council of the Institute, and will thereby be enabled to qualify for admission to the examinations of the Institute. Many have so qualified, but it is our common experience to find that the complaints come from men who have neglected to take such courses until they consider themselves past the age for doing so, and past the age for taking the examinations.

If the writers of the letters will address themselves to me, I will gladly give them what assistance I can.—I am, Sir, etc.,

RICHARD S. PILCHER
Registrar and Secretary

Institute of Chemistry
30, Russell Square, W.C. 1

CHEMICAL CO-OPERATION

Sir,—Your editorial upon the above subject in the issue of the 4th inst. touches upon points that appeal to the business instincts of many members of the Institute of Chemistry and the Society of Chemical Industry. But your call for a pioneer leader to sally forth from the wilder parts of the Kingdom, and assume an "irregular and undignified disregard of rules and regulations," has been partially anticipated by the Bristol section of the S.C.I.

During the session 1922-3, under the chairmanship of my predecessor Mr. C. J. Waterfall, one joint ordinary meeting was arranged and held by the two local sections of the societies named, and during the session just concluded, one joint ordinary meeting and a dinner were held with such success, that at a

recent committee meeting of the Bristol section of the S.C.I., a resolution was passed and forwarded to the local section of the Institute, asking their members to throw in their lot entirely with us next session, as far as ordinary meetings are concerned.

This has been accepted, and for the session 1924-5, the six winter meetings will be held jointly, and although each section will still retain its own officials, the expenses of printing and postage will be somewhat curtailed. But what is more important, the policy of peaceful penetration has commenced, and it is believed that both sections will gain by this closer contact with each other.—I am, Sir, etc.,

Bristol M. W. JONES

QUALIFIED CHEMISTS

Sir,—The British Association of Chemists has followed with considerable interest the correspondence touching "unqualified" chemists which has appeared in your *Journal*; and the more so, since those who have engaged in it, and who very properly express a desire that their status should be more exactly defined, can accomplish this through membership of the Association.

But it ought to be understood once and for all, that those who criticise the Institute of Chemistry from the point of view of these "unqualified" chemists, do not mete out to it that measure of justice to which it may properly lay claim. The Institute is a body conferring an academic qualification, and therefore is subject to the restrictions that such an activity must necessarily impose.

Doubtless necessity has from time to time dictated to the Institute a policy which, to some, may have appeared unwise; but statements as to the elasticity of their regulations where personal influence has been brought to bear ought not to be made unless ample and exact means of verification are at hand. It is not suggested that these have been lightly or carelessly made; but such statements when unaccompanied by exact and final verification, we must necessarily deprecate and deplore.

The Association is, however, an opponent of the thesis—attributed by some to the Institute of Chemistry—that those who are not members of the Institute are, by that fact, unqualified persons. And the nature of the Association's constitution is such as to give it an elasticity to which neither the Institute nor any other academic body can properly lay claim. Qualification, a word to which much violence has been done, can be other than academic; and the Association includes within its ranks some who are not academically qualified. Rigid investigation, however, is in all cases made, the standard being, of course, necessarily high.

Among the many advantages at the disposal of the members of the Association may be mentioned the unemployment benefit and legal aid funds; while the defence of the professional chemist, his dignity and economic status are the Association's first concern.—I am, Sir, etc., HENRY T. F. RHODES
(Assistant Editor *B.A.C. Journal*)
108, Baker Street, London, W. 1

SUMMARIES OF PAPERS

Sir,—Summaries fulfil the important function of enabling a reader to see at a glance the scope of a paper and the results obtained. If his attention is then sufficiently attracted he will decide for himself whether to read through the paper closely or not.

Time is thus saved to the reader, and most authors now follow the excellent practice of providing such summaries—at the end of their papers. I make the suggestion that they should come at the beginning of the paper, immediately following the title and the author's name.

Logically on account of their function this is their proper place, and to put them there would only be following the practice of putting the table of contents of a book at the beginning thereof. For a similar reason indexes should be placed at the beginning, and not at the end of a book.—I am, Sir, etc.,

A. A. JONES
Huddersfield Technical College

GASEOUS COMBUSTION AT HIGH PRESSURES

Sir,—I believe at the conclusion of my correspondence with Calorifer last year I said that, if he would possess his soul in patience until the publication of some further experimental results, he might find them luciferous. These results have now been published in a paper entitled, "Gaseous Combustion at High Pressures. Part IV.—The Influence of Varying Initial Pressures upon the Rate of Pressure Development and the Activation of Nitrogen in Carbon Monoxide-Air Explosions," by Messrs. D. M. Newitt, D. T. A. Townend and myself, which appears in the current issue of the Proceedings of the Royal Society, A., Vol. 105, pp. 406—433. We would commend a perusal of this paper to any of your readers who may be interested in the subject, as I think it makes everything perfectly clear.—I am, Sir, etc.,

WILLIAM A. BONE
Imperial College of Science and Technology
April 3, 1924

ROTATORY DISPERSION

Sir,—I agree with Dr. R. H. Pickard that the existence of dynamic isomerism in solutions of tartaric acid and its esters has not been completely proved and I regret that, through inadvertence on my part, the abstract of my paper, which appears in your issue of March 28, reads as if I held the opposite view. Dr. Pickard's objections to the application of dynamic isomerism to the tartaric acid series appear to be based upon theoretical arguments, which cannot be tested experimentally until more perfect instruments are available. My view is that there is abundant evidence to justify the retention of the only working hypothesis in existence which enables us to interpret all the available experimental evidence. More evidence is needed and more is being accumulated. It will be soon enough to abandon the hypothesis when it has been clearly shown to be contrary to facts. This has been pointed out by Dr. Walker in his letter of March 28.

So far the only other explanation of anomalous rotatory dispersion that has been given is that of Dr. W. T. Astbury (Proc. Roy. Soc., 1923, A, 718, p. 527), who attributes the anomalies of tartaric acid and many of its derivatives to the combination of two opposing spiral formations. One of these is dextrorotatory and, since it is a property of the 4-carbon nucleus of the molecule, it is stable. The lævorotatory spiral, on the other hand, is easily broken up by solvents, etc., since it depends upon the junctions between the hydroxyl groups of neighbouring molecules.

Dr. Pickard fails to see what the bearing of my work is on these deductions. The reply is perhaps best given by a quotation from Dr. Astbury's paper, in which after discussing at some length the Bakerian Lecture for 1921 (without acknowledging my share in it), he proceeds to "the conclusion that the two extremes of rotatory power are the dextro in the very dilute solutions or when the hydroxyl groups are 'fixed,' and the lævo in the crystalline form . . ." and again (in italics this time): "The dextrorotatory property of ordinary tartaric acid is associated with the carbon nucleus of the molecule."

It seems to me that these views are difficult to reconcile with the facts :

(1) That the "fixed" molecule of methylene tartaric acid is strongly lævorotatory.

(2) That its specific rotation is practically constant over a wide range of concentrations, and

(3) That the curve of its rotatory dispersion, so far as it can be explored, can be represented by one term of Drude's equation.

Further evidence on tartaric acid itself will shortly be available for publication.—I am, Sir, etc.,

THE EPILATION OF SKINS

Sir.—I have again read Mr. Wood's paper to which he refers and which contains the test for enzyme action that he claims shows that my researches are wrong. It apparently consists of mixing a dilute solution of gelatin with a powdered extract of a conglomeration of organs of a dog's alimentary tract. If, after a certain time, at a certain temperature, the gelatin refuses to coagulate on boiling, he says that it is all peptonised by enzyme action, or, if the reverse, there is no enzyme present. Heavens! how can he genuinely assert either? He makes the same assertion, using the same tests for limes and soak liquors in the tannery. How can he preclude that the gelatin has become so swollen with dropsical imbibition that it can no longer coagulate, or that there are no new coenzymes, or inhibiters, or adsorption compounds that may bring the enzymes to equilibrium, etc., in his conglomerate mixture? Further, he asks us to trust his German test with gelatin as one for the effect of the limes on the skin. There is no gelatin in the skin as the tanner uses it. There may be a hundred fallacies in his test.

But it is of little use arguing with Mr. Wood and his preconceived ideas. He, like several others, seem to have missed the gist of my researches tha[t] if you remove the two enzymes from the ski[n] neither lime nor ammonia nor xylol, etc., will unhai[r] it. He states that thrombase is not a proteoclasti[c] enzyme and that it will not unhair a hide. O[n] my table as I write are many yards of artificia[l] furs made out of the hair and epidermis remove[d] from hides by thrombase proteoelasm, and th[e] leather made from the same pelts is, according t[o] experts, as good as or even better than what i[s] usually made to-day. "The proof of the pudding . . ."—I am, Sir, etc.,

H. C. Ross

PERSONAL AND OTHER NOTES

The President and Council of the Royal Society have appointed Prof. O. W. Richardson, F.R.S., to be the third Yarrow research professor of the Royal Society. Prof. Richardson, who is Wheatstone professor of physics in King's College, London, will remain a member of King's College and will continue to carry out his researches there.

We regret to announce the death, on March 28, of Mr. A. E. Tucker, at the age of 70. Mr. Tucker had practised in Birmingham for 40 years, mainly in metallurgical research and analysis, and had held the office of official analyst to the London Metal Exchange. He was a member of several scientific societies, and had served as chairman and member of the committee of the Birmingham and Midland Section, before which he read, some time ago, a paper on metal colouring. He leaves a widow and three sons.

Prof. G. Poma, professor of industrial chemistry in the Royal School of Engineering, Padua, and technical director of the Bonelli dyestuff factory, has died, aged 42 years.

Prof. E. Paternò has been appointed professor emeritus in the faculty of science of the University of Rome. Prof. R. Nasini has been appointed director of the pharmaceutical school of the University of Pisa. Prof. M. G. Levi has been nominated a member of the committee for the preparation of the national mobilisation of Italy.

Gilbert Baldwin, the chief chemist to the Mathieson Chemical Co., Niagara Falls, N.Y., was killed on February 22 by an explosion in the synthetic ammonia plant.

By the will of Miss Caroline Harrold, who left estate of the value of £26,681, the ultimate residue of the estate is to go to the University of Birmingham, for affording facilities and opportunities for research in the Faculties of Science and Medicine.

Dr. A. E. Houlehan, who died at Delaware on March 11, aged 39, was assistant director of the Wilmington experimental station of the Du Pont Co., and was responsible for important developments in the manufacture of organic chemicals required during the war. He later took a prominent part in organising research in dye manufacture for the Du Pont Co. Dr. Houlehan was a member of the Society of Chemical Industry.

The Royal Society has received from Messrs. Brunner, Mond & Co., a gift of 500 guineas for use in publishing the results of research in chemistry, physics and allied sciences.

The executive committee of the National Italian Congress of Industrial Chemistry, which is to be held in Milan from April 12 to 17, has decided to award the sum of 50,000 lire, as a whole or in part, for the best original papers dealing with applied chemistry read by Italian authors at the Congress.

The Council of the University of Manchester has received £507 to be invested and known as the "Professor Harold Baily Dixon Bursary Fund." The income of this fund, which will be administered by a committee appointed by the Council, will be used to assist students in the Department of Chemistry who may be in need of financial assistance in order to complete their degree courses. This sum represents the balance left after defraying the cost of the bust of Prof. Dixon, which has been placed in the Chemical Theatre of the University.

Dr. W. R. Ormandy has been elected president of the Institution of Automobile Engineers for the session 1924-1925.

On April 2, states the *Chemiker Zeitung*, Prof. Oscar Loew, "the Nestor of German agricultural chemists and plant physiologists" celebrated his eightieth birthday. Investigations on the chemical problems of life, the formation and properties of formaldehyde, the nutrition of plants, the use of lime and magnesia as soil dressings and many other subjects show the extent of Loew's interests.

German Dye Agreement

It is reported from Berlin that a large number of shares have been exchanged between the Basel Farbstoff Werke, Switzerland, and a large German dye company, as the result of an agreement regulating prices, conditions of sales and areas of market.

Methods of Analysis of Coal—Determination of Nitrogen

Experiments made subsequent to the issue of the description of the methods of analysis recommended by the Sampling and Analysis of Coal Committee of the Fuel Research Board have shown that the particular modification of the Kjeldahl method for the determination of nitrogen, described on pages 7 and 8 of their interim report (Fuel Research Board, Physical and Chemical Survey of the National Coal Resources, No. 2, "Interim Report on Methods of Analysis of Coal," 1923. H.M. Stationery Office. Price 1s. 6d. net) gives perfectly reliable results; there is a close agreement between the results of this method and those obtained by a proved modification of the Dumas method ("The Estimation of Nitrogen in Coal," by A. Baranov and R. A. Mott, *Fuel*, 1924, 3, 31, 49). It has also recently been proved that copper sulphate is *not* a suitable substitute for mercury, as stated in a footnote on page 7 of the interim report, since its use yields, in general, low results.

The Chartered Electrical Engineer

The following is part of a new by-law of the Institution of Electrical Engineers, which was adopted at a Special General Meeting of the Corporate members, held on February 28, 1924, and was allowed by the Lords of His Majesty's Most Honourable Privy Council on March 20, 1924:—

"Every member and associate member is, and is entitled to describe himself as, a Chartered Electrical Engineer, and in using that description after his name shall place it after the designation of the class in the Institution to which he belongs, stated in accordance with the following abbreviated forms, namely, M.I.E.E. or A.M.I.E.E., as the case may be."

Errata

In the account of the meeting of the Biochemical Society, published in the issue for March 21, the following corrections should be made:—P. 313, col. ii., line 1, for "doses of 15 c.c." read "doses of 5 c.c." Line 11, for "Mr. E. M. Luce," read "Dr. E. M. Luce." Line 40, for "than pasture-fed milk" read "than 5 c.c. of pasture-fed milk."

FRANCE

Potash in 1923

The French production of potash salts in 1923 totalled 1,275,429 metric tons, equivalent to 248,698 t. K_2O, compared with 1,052,217 t. (207,119 t. K_2O) in 1922. The production in 1923 included 409,535 t. of crude salts (12 to 15 per cent. K_2O), 350,039 t. of manure salts (20 to 22 per cent. K_2O), 110,529 t. of manure salts (30 to 40 per cent. K_2O) and 156,638 t. of chlorides (with over 50 per cent. K_2O). The chief exports were: United States, 5583 t. chloride; Great Britain, 18,195 t. chloride, and Netherlands, 40,100 t. chloride. In January, 1924, the production of potash salts was 125,914 t. (27,487 t. K_2O).

Milk Production in France

According to official statistics of the French Ministry of Agriculture, the production of milk was 106,503,550 hectolitres in 1921, 113,276,970 hl. in 1922, and 112,058,120 hl. in 1923.

AUSTRALIA

Pulverised Coal in Victoria

Experiments by the Victorian Railways on the use of pulverised brown coal as engine fuel, have given satisfactory results, including, it is stated, a large saving in fuel, labour and time, and similar results have been obtained under boiler plant at Newport.

UNITED STATES

Improved Catalyst for Nitrogen Fixation

It is announced from the United States that the Fixed Nitrogen Research Laboratory of the Department of Agriculture has developed a new catalyst with which yields of 14 per cent. of ammonia has been obtained during continuous running. The German catalyst gives a yield of 7 per cent. and its life is much shorter.

REVIEWS

Chemisch-Technische Vorschriften. *By* Dr. Otto Lange. Vol. III. Harze, Oele, Fette. *Pp.* xix+796. *Third edition, enlarged, and fully revised. Leipzig: Otto Spamer,* 1923. *Price, paper 50 goldmarks, bound 75 goldmarks.*

The volume forming the subject of the present review deals with the chemistry and technology of rubber, resins, gums and turpentine; petroleum and its products, including asphalt, tar and pitch; fatty oils and waxes and their related industries; hydrogenation; stearine, oleine and the soap and candle industries; perfumes and toilet preparations; disinfectants, sterilising agents and preservatives; water and industrial effluents; insecticides, fungicides and germicides.

When one reflects that Dr. Otto Lange's *Chemisch-Technische Vorschriften* is a work of six volumes each more or less comparable in bulk with this under review, one wonders whether to admire or to condole with him in essaying unaided the task he has undertaken. There is in the present volume alone material requiring the collaboration of at least half a dozen experts each having an exhaustive and critical knowledge of some main section of the work, for, frankly, it is impossible for one author to deal effectively with the many and diverse subjects included here for the all-sufficient reason that to do so requires an intimate working knowledge of the various industries which are within the purview of the volume and one is not convinced that the author at all times possesses this necessary qualification. Consequently, the faults are such as one expects to find: there is a want of balance, a disposition to give much detail where brevity would suffice with the corresponding fault of dealing only scantily with subjects of well-recognised importance, and an absence of that critical discussion of data which, in many cases, would help to guide the reader.

Despite the bewildering amount of information contained in this volume—and its closely written 800 pages contain thousands of references to patent specifications and published technical and scientific papers—one is impressed by the omission of much that is of real importance and more particularly by the fact that the books, technical papers and patents to which reference is made in the text are almost entirely German and this partiality, for which there is no possible justification, constitutes a very serious defect in the volume, a defect which greatly detracts from its value as a work of reference.

The general plan of the book is quite good and its sub-division into chapters with appropriate headings facilitates a grasp of the subject-matter. Commencing with an account of the occurrence and characteristics of the raw materials dealt with in each section, we are shown how these are exploited, converted into intermediate and final products, and the relationship of these to and bearing on other branches of chemical industry is indicated. The chemical aspect of each subject appears to be adequately treated and the author has wisely refrained from giving analytical details which can always be found in any of the well-known textbooks. The statistical information accompanying many of the chapters is useful though not always very adequate and more frequently not up-to-date.

Within the compass of a brief review it is impossible to refer in any detail to more than one or two sections, but in a careful reading of those sections which embrace the fatty oil industries one is surprised at the small amount of space devoted to the seed-crushing industry though the allied subject of extraction receives much fuller treatment. The great developments that are taking place in the cultivation of the oil palm in plantations in West Africa, and more particularly in the Dutch East Indies, leading to improved yields of the fruit, better methods of dealing with the kernels and the production of a commercial grade of palm oil greatly superior to what has usually been produced in the past, are facts which appear to have escaped the author's notice. The rendering and refining of such animal fats as tallow and lard require much fuller notice than has been accorded to them, and the same may be said in respect of butter and margarine which receive only passing mention.

The chapters devoted to an account of the methods and materials used in refining, bleaching and deodorising the fatty oils and waxes are well done and the same may be said of the treatment of such subjects as saponification, the production of stearine and oleine, the preparation of emulsified and sulphonated oils and hydrogenation. In the sections dealing with soap a good account of detergents other than soap itself is given and several interesting chapters are devoted to an account of the occurrence and properties of those curious bodies, the saponins, and their allies which frequently find use in the manufacture of vegetable soaps.

The volume will be found useful by the reader who uses it to supplement, but not to supplant, his own searches amongst chemical literature. To the very full index which has been provided an index of authors' names would have been an addition which many readers would have welcomed.

H. M. Langton

Chemical Synonyms and Trade Names. By W. Gardner. Pp. 280. London: Crosby Lockwood & Son, 1924. Price 25s.

Owing to the rapid advance of chemical industry, chemical trade names have become both numerous and confused, several different names often serving to designate a single product, and new names often giving no indication of the real nature of the product. Anything that will serve to prevent this confusion is to be welcomed, and of the attempts so far made the book under review is quite the best seen by the reviewer. A very wide ground is covered, and no noteworthy name appears to have been omitted, many uncommon names being included. Further editions will probably be wanted, and one will hope to see further condensation and the replacement of superfluous headings such as "soap" and "metal polish" by new and useful names.

LEGAL INTELLIGENCE

SAFEGUARDING OF INDUSTRIES ACT, 1921

The Referee's Award on the "rongalite" case runs as follows :—

"The question in this reference is whether sodium formaldehyde sulphoxylate and zinc formaldehyde sulphoxylate and the various forms in which they are marketed are properly included in the list published by the Board of Trade. It is unnecessary to decide whether they are fine chemicals or analytical reagents as in my opinion they are properly included in the list as synthetic organic chemicals."

"It is scarcely contended that the substances are not organic, but it is strenuously urged that the definition of synthetic organic chemicals ought to be restricted to such organic compounds as are built up from their elements or from such other organic groups as can themselves be built up from their elements. It is sought to exclude from the conception of organic synthesis those syntheses in which an inorganic molecule is combined with an organic molecule."

"In the Camphor case I refused to accept such a restricted view and I am not prepared to do so now. I think that such combinations are organic syntheses provided that they result in the formation of a structure not previously present.

"I think that the complainants have probably proceeded with this complaint relying on a recent article in the CHEMISTRY AND INDUSTRY REVIEW by Sir William Pope. They would have a strong case if that article expressed the whole view of Sir William Pope, but I am satisfied that it does not. I accept entirely his evidence as to that. Incidentally I may point out that the statement in the article that I decided that calcium carbide was not synthetic is wholly inaccurate. The question of synthesis was not dealt with at all in my award dealing with calcium carbide. Calcium carbide was not in the Board of Trade list, and I declined to order it to be inserted because I was satisfied that the Board was right in taking the view that calcium carbide was not so generally regarded as an organic chemical as to justify its inclusion."

EXCESS PROFITS DUTY

On April 4 the British Dyestuffs Corporation appealed from a judgment by Mr. Justice Rowlatt, holding that the Corporation was liable to pay excess profits duty on sums paid to them by the E. I. Du Pont de Nemours Co., for a process for synthesising indigo.

The appellant company claimed that these payments were not income, but payments for a capital asset. In 1916 the appellant company acquired a German factory at Ellesmere Port, and with it a secret process for synthesising indigo. For the right to use the process the American company agreed to pay ten annual sums of £25,000, ending in 1927. This was the sale of part of the appellant company's assets, and therefore it was wrong to regard the money received as profits.

Lord Justice Bankes said the question was whether the transaction was a sale of property for a price, or a method of trading, the price being part of the gains of trading. He read the agreement as a trading convention as to how and where the parties' respective businesses would be carried on. The annual payments were of the nature of royalties, and must be regarded as profits, so that the appeal failed.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Dyes and Dyestuffs

In a written reply to Mr. Hannon, Mr. Webb gave the following statement showing the quantities of dyes and dyestuffs (except dye-woods and raw dyeing substances) imported into and exported from the United Kingdom during the year 1923 :—

	Imports Cwt.	Exports (U.K. manufactures Cwt.	Foreign and Colonial merchandise Cwt.
Intermediate coal-tar products used in the manufacture of dyes (including aniline oil and salt, and phenylglycine)	1349	43649	75
Finished coal-tar dyestuffs—			
Alizarin	8409	22,150	7
Indigo, synthetic	8274	19,604	1
Other sorts	39,474	40,813	1577
Extracts for dyeing—			
Cochineal	773	31	450
Cutch	48,395	1395	18,807
Fustic	5997	310	173
Logwood	55,698	2140	6650
Other sorts	10,436	7584	1468
Indigo, natural	757	4	261

The direct foreign trade of the Irish Free State has been excluded from the above particulars as from April 1, 1923.—Mar. 25.

Indigo-dyed Cloth

Mr. Hartshorn, replying to Mr. Th[illegible]ne, said it had not been the practice for many y[illegible]rs past to require the use of natural indigo in the [illegible]e of Post Office uniforms; and he was inform[illegible] that by doing so additional expenditure would be incurred with no corresponding advantage. Therefore he did not feel that a deputation from the dyers would serve any useful purpose.—Mar. 25.

Lactose

Replying to Mr. Baker's enquiry as [illegible] the reasons which actuated the Department of A[illegible]culture to decide to stop the experiments in the production of lactose, Mr. Buxton said he hoped it might be possible to continue experiments at the Ministry's lactose factory.—Mar. 31.

Oil Fuel Supplies

Mr. Trevelyan, answering Sir H. Brittain, stated that the question of the production of motor spirit and other oils from British coal was under continuous investigation by the Fuel Research Board, both by researches at the Fuel Research Station, Greenwich, and by a close study of other attempts to solve the problem at home and abroad.—Apr. 2.

Chilled Meat (Formaldehyde Preservative)

Answering Captain Viscount Curzon, Mr. Wheatley said that the quantity of chilled meat being imported on the s.s. "Kent" is 463 quarters, and he was not aware that any arrangements had been made for further consignments of meat treated by formaldehyde. The Departmental Committee on Preservatives in Food had proposed to arrange for the inspection and investigation of the process for the general purposes of their enquiry.—April 1.

Fuel Research Board

In answer to Sir H. Brittain, Mr. Trevelyan said that the Board had produced from coal on a large experimental scale both a suitable fuel oil for naval and commercial purposes and an efficient solid fuel to take the place of raw coal. The Board, however, believed that neither its own work nor that of any outside body had yet proved the economic possibility of such production on a national scale.—Apr. 2.

Patent and Trade Mark Laws

In a written answer to Mr. Hannon, Mr. Webb said that he was aware of the lack of uniformity in the patent and trade mark laws of the countries signatory to the Industrial Property Convention of 1883, which was last revised at Washington in 1911. Every effort had been made in the past to obtain greater uniformity in the general principles of patent and trade mark legislation in the contracting States, and it was hoped that at the next Convention a further advance in this direction would be made.—Apr. 2.

COMPANY NEWS

BRITISH ALUMINIUM CO., LTD.

Including a carry forward of £15,778, the net profit for 1923 is £111,123, after providing for taxation, debenture stock, and setting aside £50,000 for depreciation, and £60,000 for reserve (now at £280,000). After providing for the dividend on the preference shares and an interim dividend of 5 per cent. on the ordinary shares, a final dividend is recommended of 10 per cent. per annum on the ordinary shares, making 7½ per cent. for the year, and leaving £18,071 to be carried forward. In 1922, the profit was £83,804, £30,000 was placed to depreciation reserve, £10,000 to reserve, and after paying 5 per cent. on the ordinary shares, £15,778 was carried forward. The report states that all the works operated at full production during 1923 and the demand for metal showed a continued increase.

BELL'S UNITED ASBESTOS CO., LTD.

The net profit for 1923 was £36,525 (£36,850 in 1922), and £37,911 was brought forward. It is proposed to pay a final dividend on the ordinary shares of 7½ per cent., making 10 per cent. for the year; to place £10,000 to reserve, leaving £31,483 to be carried forward. The report states that following the amalgamation of the Poilite and Everite businesses substantial savings have been effected by co-operative working.

MIRRLEES WATSON, LTD.

Credit balance on profit and loss account after deducting depreciation, directors' fees, and other provisions, amounts to £15,601, which, with balance brought forward, £4,086, makes available £19,687. It is recommended that £14,404 be applied in payment of dividend of 10 per cent., leaving £5,283 to be carried forward. Balance of profit for previous year was £2,929, and similar dividend was paid.

THARSIS SULPHUR AND COPPER CO., LTD.

A dividend of 10 per cent., less tax, is recommended for 1923. After writing off £27,486, £30,225 is carried forward.

LEVER BROTHERS, LTD.

The profit balance is £5,071,978 (an increase of £146,960), leaving £4,326,858 for dividends on the preference and preferred preference shares, £197,427 for the co-partnership dividend, and £240,000 (10 per cent.) for the ordinary dividend. £250,000 is placed to reserve and £57,693 carried forward. The capital of the company stands at £51,475,363 and reserves stand at £2,732,664.

ASSOCIATED PORTLAND CEMENT MANUFACTURERS, LTD.

The directors regret inability to recommend the payment of a dividend on the ordinary shares for 1923. After providing for preference dividend and placing £218,600 to reserve, £227,478 remains to be carried forward, as against £227,400 brought in. The decrease in profits is largely due to low export prices.

BRITISH PORTLAND CEMENT MANUFACTURERS, LTD.

At the ordinary general meeting it was stated that the debentures had been reduced by £28,347, sundry creditors had increased by £117,040 to £452,875, and investments and loans had increased by £645,202. The net profit for the year was £208,669 (£210,578) and including the carry-forward £393,812 remained for disposal. Investments had given satisfactory returns, but the Indian company had made a loss, owing to over production in India. The ordinary shares of the Humber Portland Cement Co. had been acquired for £600,000 by a subsidiary company. The demand for cement, though better, fell short of expectations, and competition was very severe, but a larger demand was anticipated in the future. It was decided to pay the preference dividend and a dividend of 10 per cent. on the ordinary shares, leaving a carry-forward of £187,751.

UNITED GLASS BOTTLE MANUFACTURERS, LTD.

Sir E. F. Oldham, speaking at the general meeting, said the company was in a sound financial position and that its business continued to expand, particularly in the export trade. The net profit was £43,388, and after making substantial depreciations and reserves, and including other amounts, there remained a net balance of £130,280. After paying debenture interest, enough remained to cover the interest on the preference shares, but it was considered advisable to defer payment for the present, in order to provide more working capital.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals .. .	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity. f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide ..	Expected to advance in sympathy with the crude metal.
Golden	5¼d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide ..	4s. per lb.
Carbon Bisulphide ..	£24—£26 10s. per ton according to quantity.
Carbon Black	Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride ..	£56 per ton, drums free.
Chromium Oxide ..	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hypo sulphite ..	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep ..	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£21 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 10s. per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall., 60% O.P. Dull market.
Solvent	5s. per gall. 10% O.P. Dull market.
Wood Tar	£5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead ..	£47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7¾d.—8d. per lb. Better demand, and firmer market. London prices reported up to 9d.
Crude 60's	2s.—2s. 3d. per gall. Market not so good.
Acid Cresylic, 97/99 ..	1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor ..	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Pure	1s. 8d.—1s. 11d. per gall.

Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 10½d. per gall. Few inquiries.
Middle Oil .. } 7¾d.—8½d. per gall. according to grade and district. Market again weaker.
Heavy .. .. }
Standard Specification }
Naphtha—
Crude .. .. .. 8d.—9d. per gall. } Better demand.
Solvent 90/160 .. 1s. 2d.—1s. 5d. } Prices show up-
Solvent 90/190 .. 1s. 2d.—1s. 3d. } ward tendency.
Naphthalene Crude—
Drained Creosote Salts £6—£7 10s. Demand not so good.
Whizzed or hot pressed £9 10s.—£12 per ton. Not much inquiry.
Naphthalene—
Crystals and Flaked .. £17—£18 per ton.
Pitch, medium soft .. 52s. 6d.—57s. 6d. per ton. Market again weaker.
Pyridine 90/140 .. 18s.—19s. per gall. Demand well maintained. Price again advanced.
Heavy .. 11s.—12s. Occasional inquiries; little business.

INTERMEDIATES AND DYES

Business in dyestuffs has increased and reflects an improvement in the textile trade. Orders have been for larger quantities than of late. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 9d. per lb. 100% basis d/d.
Acid Salicylic, tech .. 1s. 4d. per lb. Steady demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7½d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. [illegible] moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene 48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 2d. per lb. d/d.
Monochlorbenzol .. .. £63 per ton.
α-Naphthol .. .. 2s. 5d. per lb. d/d.
β Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 4½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 4d. per lb. d/d.
Nitrobenzene .. .. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. 11¾d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 2d. per lb. d/d.
p-Phenylene Diamine .. 10s. 4d. per lb. 100% basis d/d.
R. Salt .. .. .. 2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 6d. per lb. 100% basis d/d.
o-Toluidine .. .. 8½d. per lb.
p-Toluidine .. .. 3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine .. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is lifeless, values remaining at a low level.

Acid, Acetic 80% B.P. .. £48 per ton. Market easier.
Acid, Acetyl Salicylic .. 3s. 5d.—3s. 9d. per lb. Easier.
Acid, Benzoic .. .. Commercial acid 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. lb.
Acid, Boric B.P. .. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric .. .. 19s.—21s. per lb.
Acid, Citric .. .. 1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic .. .. 3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst. .. 6s. per lb., for 28 lb. lots.
Acid, Salicylic .. .. Prices quoted from 2s. 3d. per lb. down to 1s. 10d. for ton lots. Market rather weak.
Acid, Tannic B.P. .. 3s. per lb. Market quiet.
Acid, Tartaric .. .. 1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol .. .. .. 9s. per lb. d/d.
Acetanilide .. .. 2s. 6d. per lb. for quantity. Very weak.
Amidopyrin .. .. 13s. 6d. per lb.
Ammon. Benzoate .. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P. £37 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make.
Barbitone .. .. 15s. 6d. per lb. Weak market.
Benzonaphthol .. .. 6s. 3d. per lb. Firmer.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides— Market very firm and advancing. Heavy increase in price of bromine.
Potassium .. .. 10d.—10½d. per lb.
Sodium .. .. 10d.—10½d. "
Ammonium .. .. 11d.—1s. "
Calcium Lactate .. Prices vary over a wide range. Good English make can be had from 1s. 7d. to 2s. 3d. per lb.
Chloral Hydrate .. .. 3s. 9d. per lb.
Chloroform .. .. 2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate .. 6s. per lb. Little demand.
Guaiacol Carbonate .. 13s. per lb. for cwt. lots.
Hexamine .. .. 3s. 6d.—3s. 9d. per lb. for foreign makes. Weaker. Without much inquiry. Large stocks.
Homatropine Hydrobro-

Hydroquinone .. .. 4s. 3d. per lb. Foreign make.
Iron. Ammon. Citrate B.P. 1s. 11d.—2s. 3d. per lb., according to quantity.

Magnesium Carbonate—
Light Commercial .. £36 per ton net.
Magnesium Oxide—
Light Commercial .. £75 per ton, less 2½%.
Heavy Commercial .. £20 per ton, less 2½%.
Heavy Pure .. .. 2s.—2s. 3d. per lb., according to quantity. Steady market.

Menthol—
A.B.R. recryst. B.P. .. 67s. 6d. Strong upward movement due to disappointing Japanese crop.
Synthetic .. .. 20s.—35s. per lb., according to quantity. English make. Steady demand.

Mercurials .. .. Very much firmer in view of the rise in the price of quicksilver. Prices have been advanced by 6d. per lb.
Red oxide .. .. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate .. 3s. 6d.—3s. 7d. „
White precip. .. .. 4s. 7d.—4s. 8d. „
Calomel .. .. 3s. 11d.—4s. „
Methyl Salicylate .. 2s. 7d.—2s. 9d. per lb. for carboys. Weaker than other salicylates.
Methyl Sulphonal .. 25s. per lb. neglected.
Paraformaldehyde .. 3s. 6d. per lb., without much inquiry.
Paraldehyde .. .. 1s. 4d.—1s. 7d. per lb. in free bottles and cases.
Phenacetin .. .. 6s. 6d. per lb.
Phenazone .. .. 8s. per lb. for cwt. lots. Spot prices much lower than forward offers. Firmer tendency.
Phenolphthalein .. .. 7s. 3d.—7s. 6d. per lb. Firm.
Potass. Bitartrate—
99/100% (Cream of Tartar) .. .. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate .. .. 1s. 8d.—2s. per lb.
Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite .. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—
B.P. Crystal .. .. 8¾d.—9d. per lb. carriage paid. English make.
Commercial .. .. 8d.—8¼d. per lb. carriage paid. English make.
Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin .. .. .. 6s. 3d. per lb.
Salol .. .. .. 3s. 9d. per lb.
Silver proteinate .. 9s. 6d. per lb.
Sod. Benzoate, B.P. .. 3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923 1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—
Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside .. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) .. 76s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate .. .. Market firmer. Powder 2s. 5d.—2s. 9d. per lb. Crystal at 2s. 9d.—2s. 11d. per lb. Flake 2s. 10d.—3s. 4d. per lb.
Sod. Sulphide—
Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous £27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal .. .. .. 18s. 6d. per lb.
Tartar Emetic .. .. 1s. 4d. per lb.
Thymol .. .. .. 13s. 6d.—15s. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone .. .. 12s. 6d. per lb.
Aubepine .. .. .. 13s. 6d. „
Amyl Acetate .. .. 2s. 9d. „ Cheaper.
Amyl Butyrate .. .. 7s. 3d. „
Amyl Salicylate .. .. 3s. 3d. „
Anethol (M.P. 21/22° C.) 4s. „
Benzyl Acetate from Chlorine-free Benzyl Alcohol 3s. 3d. „
Benzyl Alcohol free from Chlorine .. .. 3s. 3d. „
Benzaldehyde free from Chlorine .. .. 3s. 6d. „
Benzyl Benzoate .. 3s. 6d. „
Cinnamic Aldehyde Natural .. .. .. 15s. 6d. „ Cheaper.
Coumarin .. .. 20s. „
Citronellol .. .. 16s. „
Citral .. .. .. 10s. „
Ethyl Cinnamate .. 15s. „
Ethyl Phthalate .. .. 3s. 9d. „
Eugenol .. .. .. 11s. „
Geraniol (Palmarosa) .. 35s. „
Geraniol .. .. .. 11s.—18s. 6d. per lb. Advanced.
Heliotropine .. .. 8s. 3d. per lb.
Iso Eugenol .. .. 15s. 9d. „
Linalol ex Bois de Rose .. 22s. 6d. „
Linalyl Acetate .. .. 22s. 6d. „
Methyl Anthranilate .. 9s. 6d. „
Methyl Benzoate .. 6s. „
Musk Ambrette .. .. 52s. 6d. „
Musk Xylol .. .. 19s. „
Nerolin .. .. .. 4s. „
Phenyl Ethyl Acetate .. 12s. 6d. „
Phenyl Ethyl Alcohol .. 16s. „

Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patent those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before June 2nd.; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—Applications

Andrews. Grading powdered material. 7627. Mar. 25.

Bechhold, Gutlohn, and Karplus. Production of emulsions. 7749. Mar. 26. (Ger., 29.3.23.)

Campbell. Separating solids from liquids. 7719. Mar. 26.

Dunstan and Renfry. Use of adsorbent substances. 8060. Mar. 29.

Ernst. Manufacture of bimetallic thermostats. 7843. Mar. 27. (Ger., 28.3.23.)

Graham. Apparatus for separating gases from liquids. 7708. Mar. 26.

Marks. 7604. *See* II.

Marks. Centrifugal apparatus. 7605. Mar. 25.

Mayhew and Ramsay. Grinding, milling, and pulverising apparatus. 7706. Mar. 26.

Pessell. Appliances for separating liquids etc. 7522. Mar. 25.

Seligman. Apparatus for effecting interchange of heat. 7616. Mar. 25. (July 18, 1923.)

Soc. Chimique de la Grande-Paroisse (Azote et Produits Chimiques). Purification of gases. 7697. Mar. 26. (Fr., 4.6.23.)

Urbain. Treatment of gases etc. 7187. Mar. 24. (Fr., 13.2.23.)

I.—Complete Specifications Accepted

31,807 (1922). Nielsen and Laing. Rotary retorts, kilns, dryers, or the like. (212,961.)

34,477 (1922). Reynolds and Brewin and Dickin. Grinding-mills. (212,978.)

34,850 (1922). Dorr Co. Treatment of pulps. (190,727.)

35,441 (1922). Tanier. Furnaces. (213,014.)

8769 (1923). Monkbridge Iron and Steel Co., Ltd., Kitson and Brown. (213,119.)

12,890 (1923). Young and Greene. Crushing machines. (213,151.)

63 (1924). Lawes, Apthorpe, and Cambridge and Paul Instrument Co., Ltd. (213,210.)

II.—Applications

Box, Davies, and Thompson. Separating fuel from ashes, clinker, etc. 7407. Mar. 24.

Brun. Manufacture of briquettes etc. 7979. Mar. 28. (Fr., 10.4.23.)

Cutter, Drew, and Duncalf. Process for manufacture of active absorbing carbon and phosphoric acid and its compounds. 8048. Mar. 29.

Donald. Drying peats etc. 7386. Mar. 24. 7812, 7813. Mar. 27.

Imray (Curtis). Carbonisation of coal. 7502. Mar. 24.

Marks (Peoples Saving and Trust Co. of Pittsburgh). Recovering heat of fuels at high temperatures, and recovering fusible solids in molten condition. 7604. Mar. 25.

Mons. Draining and pressing peat. 7848. Mar. 27.

Power-Gas Corp., and Rambush. Production of combustible gases and coke from bituminous fuel. 7750. Mar. 26.

Ramage. Low-temperature distillation. 7483. Mar. 24. (U.S., 9.4.23.)

Records. Liquid fuel. 7509. Mar. 24.

Soc. Chimique de la Grande-Paroisse. 7697. *See* I.

Soc. Française des Glycérines. Production of a decolorising and deodorant black composition. 7866. Mar. 27. (Fr., 1.5.23.)

Urbain. 7487. *See* I.

II.—Complete Specifications Accepted

1641 (1923). Davies. Carbonisation of coal, lignite, etc. (213,040.)

1974 (1923). Stalli. Distilling petroleum or mineral oil from oil shales, bituminous coal, etc. (213,046.)

7078 (1923). Perry. Apparatus for distilling carbonaceous material. (213,106.)

8708 (1923). Berl. Producing mixtures of oil and coal. (195,408.)

23,965 (1923). Bloxam (A.-G. für Anilin-Fabrikation). Manufacture of charcoal. (213,195.)

IV.—Application

Soc. of Chemical Industry in Basle. Manufacture of indigoid dyestuffs. 7622. Mar. 25. (Swiss, 18.7.23.)

IV.—Complete Specifications Accepted

25,351 (1922). Poma and Pellegrini. Process for the manufacture of H acid (amino-naphthol-disulphonic 1, 8, 3, 6). (190,114.)

34,368 (1922). Shannan, Siderfin, Adam, and Gas Light and Coke Co. *See* XX.

V.—Applications

Case, Garrow, and Novocretes, Ltd. Treating fibrous materials. 7823. Mar. 27.

Dreyfus. Manufacture of artificial textile products. 8059. Mar. 29.

Faust. Manufacture of artificial fibres, silk, etc. 7879. Mar. 27.

Hilton. Decorating fabrics from solutions of cellulose etc. 7772. Mar. 27.

Huebner. Production and utilisation of viscous solutions. 7882. Mar. 28.

King's Patent Agency (Duryea). Artificial fabrics. 7941. Mar. 28.

Vineke. Cork products. 7440. Mar. 24.

Vineke. Composition cork. 7441. Mar. 24.

V.—Complete Specifications Accepted

34,998 (1922). McRae. Extraction of cellulose from bamboo, bagasse, and other fibres. (213,003.)

11,009 (1923). Levy. Production of artificial filaments. (213,138.)

VI.—Applications

British Cotton and Wool Dyers' Association, and Robinson. Printing yarns etc. 7472. Mar. 24.

Geigy Soc. Anon. Dyeing or printing on acetyl cellulose. 7817. Mar. 27. (Ger., 31.3.23.)

Mairesse. Colour printing upon textiles, leathers, etc. 7436. Mar. 24. (Fr., 24.3.23.)

VI.—Complete Specification Accepted

19,187 (1923). Schlumpe. Hank-dyeing and like machines. (201,565.) July 31.

VII. Applications

Coley. Reduction of carbonates or bi-carbonates. 7427. Mar. 24.

Coloy. Reduction of sulphates. 7428. Mar. 24.

Cutter, Drew, and Duncalf. 8048. *See* II.

Henkel et Cie. Manufacture of mouldings of solid oluble alkali silicates. 7875. Mar. 27. (Ger., 2.5.23.)

Kassner. Manufacture of nitric acid etc. 7484. Mar. 24. (Ger., 31.3.23.)

Meyerhofer. Process of producing inorganic acids. 7862. Mar. 27. (Ger., 28.3.23.)

VII.—Complete Specification Accepted

5499 (1923). Cruse. Manufacture of acetate of alumina by electrolysis. (213,088.)

VIII.—Application

Cachemaille (Westinghouse Lamp Co.). Application of ranslucent coatings to vitreous objects. 8040. Mar. 29.

VIII.—Complete Specification Accepted

34,651 (1922). Vivian. Drying china clay. (212,986.)

IX.—Applications

King. Hard-setting compositions. 7856. Mar. 27.

Rekord-Zement Industrie Ges., and Tetens. Manufacture of concretes and mortars. 7620. Mar. 25.

IX. Complete Specification Accepted

17,139 (1923.) Cullerier. Treating marble to render it ranslucent. (202,282.)

X.—Applications

Coley. 7427 and 7428. *See* VII.

Metallbank und Metallurgische Ges. A.-G. Alloys and metals. 7519. Mar. 24. (Ger., 31.3.23.)

Rondelli. Testing corrosion of ferrous etc. materials. 7760. Mar. 26.

X. Complete Specifications Accepted

28,618 (1922). Jackson (Soc. Anon. J. Cockerill). Treatment of ores containing iron or other metal. (197,903.)

34,600 (1922). O'Donovan. Hardening steel articles. (205,037.)

XI.—Application

Pourbaix. Production of ozone. 7973. Mar. 28.

XI.—Complete Specifications Accepted

4813 (1923). Weissmann. Dry cells. (213,082.)

5499 (1923). Cruse. *See* VII.

XII.—Applications

Bechhold, Gotlohn, and Karplus. 7749. *See* I.

Bray. Manufacture of oil from vulcanized rubber. 7691. Mar. 26. (Belg. 18.12.23.)

Francesconi and Gaslini. Refining fats and oils. 7967. Mar. 28. (Italy, 26.11.23.)

Franke. Cooling-apparatus for production of crystallised oap powder etc. 7538. Mar. 25.

Pourbaix. 7973. *See* XI.

XII.—Complete Specification Accepted

34,743 (1922). Petroff. *See* XX.

XIII.—Application

King. Paints. 7857. Mar. 27.

XIV. Applications

Bray. 7691. *See* XII.

Ditmar. Manufacture of india-rubber etc. articles. 7844. Mar. 27. (Austria, 9.4.23.)

Ditmar. Manufacture of cellulose-caoutchouc products. 7845. Mar. 27. (Austria, 9.4.23.)

Peachey and Skipsey. Vulcanisation of caoutchouc. 7648. Mar. 26.

XV. Applications

British-American Tobacco Co. (Beckley). Obtainment of printed reproductions of photographs on metal. 7826. Mar. 27.

Mairesse. 7436. *See* VI.

XV. Complete Specification Accepted

22,129 (1923). Hoffmans. Cooling and drying glue, gelatin, and the like. (213,190.)

XIX.—Applications

Anderson and Karpinsky. Manufacture of butter. 7606. Mar. 25. (Fr., 16.4.23.)

Radcliffe. Purification of waste effluents. 7563. Mar. 25.

Sonsthagen. Treating chocolate etc. 7835. Mar. 27.

XIX.—Complete Specifications Accepted

17,500 (1923). Schoen. Flours etc. (203,661.)

1921 (1924.) Declercq. Water-purifying apparatus. (210,438.)

XX.—Applications

34,368 (1922). Shannon, Siderfin, Adam, and Gas Light and Coke Co. Manufacture of organic compounds by reactions involving replacement of substituent atoms or groups with liquid reagents. (212,970.)

34,743 (1922). Petroff. Separating oxidised fatty acids from non-oxidised fatty acids. (212,900.)

XXI.—Application

A.-G. für Anilin-Fabrikation, and Wilmanns. Negatives for photomechanical printing. 7754. Mar. 26.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—

Argentina: Aluminium, chinaware, earthenware, iron, cutlery, glassware, paper, paint and varnish (391); *Australia*: Iron and steel (353); Hardware, paint (Official Secretary, Commercial Bureau, Australia House, Strand, W.C. 2, No. 412/7/1/1/222): *Canada*: Brass foundry, hardware (355); Builders' hardware, paint, cutlery, crockery (358, 359); Plumbing supplies (13.396/E.D./G.C./2); *Chile*: Earthenware, hardware (393); *Dominican Republic*: Soap (394): *Egypt*: Leather (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W. 1); *Latvia*: Asbestos packing (8842/F.R./M.C./2); *Netherlands* Cutlery, leather (366); Brass tubes (368): Silk (370); *New Zealand*: Artificial silk (360); *Sweden*: Chemicals (375).

Foreign Company News

The Société de Soie Artificielle de Tubize has acquired at Lyons a large area of land for the construction of a factory for the manufacture of cellulose acetate silk by its associated company, La Célanèse Française. Plant to produce 500 kg. of artificial silk per day will be installed at first, but the plans provide for an ultimate daily production of 4000 kg. The production at Tubize is now 6000 kg. per day of collodion silk, and 500 to 600 kg. of viscose silk, and in 1924 it is expected to produce a total of from 8000 to 9000 kg. per day. The production of associated companies comprises 1500 kg. per day at Sarvaar, 25 kg. per day at Tomafzew, and 600 kg. per day in America, where production is increasing rapidly. The problem of dyeing cellulose acetate silk has been solved and at Lyons the dyers are taking great interest in it.

Owing to the amalgamation of the Société Industrielle du Celluloide with the Société Générale pour la fabrication des matières plastiques, the new company will be entitled Société Industrielle des Matières Plastiques.

Santonin

The Eastern and Russian Trading Co., Ltd., has sent a booklet and other literature, describing the properties and production of santonin, a valuable anthelmintic obtained from *Artemisia cenæ*, a plant which grows abundantly in Turkestan. Some of the literature received describes tests carried out by the Pharmaco-Therapeutic Institute, Leyden, on "santoperonin": the tests seem to show that this compound is inadvisable as a substitute for santonin.

Trade Information

Messrs. Williams Bros. & Co., of Hounslow, have sent a series of pattern cards illustrating the wide range of colours for all purposes which they manufacture. Special prominence is given to the Nigrosines and Blacks with which this firm is particularly associated, but all kinds of colours for varnish, lacquers, wood, leather, polishes, inks, soap makers and dyes for a variety of textiles are also made. Colours are provided for lake makers suitable for use with any material or solvent, and a speciality is the supply of harmless colours for foodstuffs. Careful matching to requirements is undertaken by a special staff, and Messrs. Williams are glad to supply special lists on application.

Messrs. Meldrums, Ltd., of Timperley, near Manchester, have sent a leaflet (F. D. Supplement) describing the Meldrum forced draught furnace, which was the pioneer in steam-jet furnaces 35 years ago, but which has been continuously improved. Special features claimed for these furnaces are their sturdy construction, efficiency, adaptability to all types of steam-boilers and their ability to utilise all classes of fuel. Messrs. Meldrums have introduced a new design of acid pump in Meldrum metal proof against mineral acids at any strength or temperature. The new design gives greater efficiency and a pamphlet (C 25/6) is supplied in which a graph is given showing the relation between head and output at different speeds, together with a table giving lifts, capacities and speeds of pumps from 1 to 6 in.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during March has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 534, of which 415 were from merchants or importers. To these should be added 17 cases outstanding on March 1, making a total for the month of 551. These were dealt with as follows:—

Granted, 420 (of which 380 were dealt with within 7 days of receipt).

Referred to British makers of similar products, 83 (of which 69 were dealt with within 7 days of receipt).

Referred to reparation supplies available, 26 (all dealt with within two days of receipt). Outstanding on March 31, 1924, 22.

Of the total of 551 applications received, 475, or 86 per cent., were dealt with within 7 days of receipt.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, APRIL 18, 1924 No. 16

EDITORIAL

THE discussion and consideration of the schemes for Chemistry House proceeds with that alacrity which is possible when complicated and revolutionary ideas are evolved which affect some ten thousand chemists. No doubt there are some who wish and intend that some definite step be taken at once, no doubt there are many whose imagination is only fired by such a scheme to an extent which produces a slow and low-temperature carbonisation. The scientific spirit which pervades the majority of chemists tends to a careful and methodical study of the problem in a tranquil frame of mind free from every trace of passion, and with no feeling of surprise or prejudice because the scheme is, or is not, the offspring of some particular individual or body or is, or is not, approved by bodies only indirectly concerned. The great majority of chemists already favour the scheme, the details are as yet known only to a few and when the details are disclosed and approved by a council or a committee which has the confidence of the great body of chemists the force behind the scheme—if any further force is needed—will steadily increase. No question of *amour propre* on the part of those who have propounded schemes which are accepted, rejected or postponed, need enter into consideration. All those who have been or are now busy with the scheme are devoting their time and energy unselfishly for the common good. The resolutions passed at the Club at last Monday's meeting show how great an advance has been made in the last few years.

* * *

How many perils do environ the man that meddles with cold iron! The engineering section of the British Empire Exhibition shows that chemists have meddled with cold iron to some purpose. We do not remember that we have ever seen any pure iron, but we assume that it is a disappointing material. The introduction of carbon into it is so long past that the memory of man runneth not to the contrary. The introduction of manganese, molybdenum, nickel, chromium, vanadium and titanium is due to the chemist as is the scientific investigation of the effect of the varying proportions of carbon, silicon, sulphur and phosphorus. Will the fulness of time give us a new metal? We have delved into the bowels of the earth to a distance of a few thousand feet and the geologist can assure us of the nature of the rocks for during a vertical distance of perhaps half a dozen or ten miles. We are apt to assume that what we know is a fair sample of the bulk, and we have often seen calculations of the relative proportions of the elements and how much is contributed by those of odd, and of even, atomic numbers. But we have every reason to think that the ·1 per cent. or whatever it is which we know is not a representative sample. The rocks at the surface have a density of about two and a half; the earth as a whole has a density of twice as much. We can no more judge of the nature of the earth from the thin skin we have observed than we can judge of the British Empire Exhibition from the first restaurant visited. Next week we shall give a long account of this great achievement in the Special British Empire Exhibition Number which we are now engaged in preparing.

* * *

The last days before the opening of the British Empire Exhibition are upon us. There is feverish activity in all the wide spaces of the Palace of Industry and the last exhibits are being delivered in lorries, carts, trains and any means of conveyance that can find a way down the crowded aisles. The dignified and continuous front of the exhibit of the chemical industries is adorned with the effective frieze depicting familiar operations in the chemical world, industrial and scientific, and tall, handsomely gilt columns with lotus capitals border the thoroughfares, bearing emblems appropriate to the particular industries before which they stand. The exhibit relating to pure science is—but that must await the official opening and our Special Number, there are so many good things.

THE FERMENTATION OF CACAO

By A. W. KNAPP

It is not possible by reference to published records to compile a complete scientific explanation of the fermentation of cacao. Many planters know how to carry out the process to the satisfaction of the buyers of cacao beans (as the seeds of the cacao tree are called), but those who superintend the work on the cacao estates have generally lacked the training and equipment to investigate the theory of the subject. On the other hand the scientists in Europe seldom have an intimate knowledge of the process, and are unable to obtain the fresh seeds on which to experiment. Even if they had the knowledge and the material, they would still find it difficult to lay down the best conditions to maintain, as the cocoa and chocolate manufacturers as a body have never stated exactly what they want. However, they do go so far as to indicate a preference for fermented cacao by paying more for it than for unfermented cacao from the same country.

Now that we have Agricultural Colleges in Trinidad and other tropical places we may expect to see great advances in this subject, as there is no doubt that a well-equipped bio-chemist on the spot could unravel many of the problems in a short time. It is proposed to give a critical review of the position as it stands to-day, together with an account of some experiments of the author.

The Cacao Seed or Bean

The fresh seed consists of two folded fleshy cotyledons and a white radicle (germ), enclosed in a leathery skin. As taken from the pod it is surrounded by a whitish mucilaginous pulp. There are two distinct kinds of seeds, those from the Criollo variety of tree and those from the Forastero variety. The principal difference is that the Criollo beans are white throughout, whilst the Forastero are purple. As over 90 per cent. of the world's cacao is Forastero, this paper deals mainly with this variety. Until we have more knowledge we may assume that the Forastero bean contains the same chemical substances as the Criollo, and in addition a purple tannin.

The beans have to be dried to make them a stable article of commerce, and as they dry more easily if they have been fermented, this was probably the original object of fermentation. It is an easy way of getting rid of the pulp. In Ceylon, where the pulp is removed by washing, it is first loosened by fermentation.

The amount of pulp on the seeds varies with the season. The pulp contains about 80 per cent. of water. Roughly speaking, 100 lb. of seeds fresh from the pod, if merely dried, lose about 61 lb. of water. During fermentation they lose about 11 lb. by evaporation, and 13 lb. of a liquid, known as "sweatings," runs away. On drying the fermented bean a further loss of 40 lb. by evaporation occurs, making a total of 64 lb. According to Hudson[5] from 100 lb. of fresh beans one obtains 39 lb. of unfermented cacao beans of commerce by merely drying, or 36 lb. of fermented beans of commerce by fermentation and drying.

The beans may be fermented by being put in heaps or in boxes, the latter being the more usual method. The bottoms of the boxes are usually perforated to allow the "sweatings" to run away, and the beans are generally covered with a layer of plantain leaves. The beans are usually turned from one box to another once a day, or every other day. The temperature of the mass rises, and the pulp breaks down and partly runs away. With Forastero cacao after six or seven days the pulp on the outside of the beans is a dirty brown, and the planter judges whether the cacao is fermented and ready for drying solely by observing this colour.

Fermentation of the Pulp

The following analyses of the "sweatings" (made in Messrs. Cadbury's Research Laboratory mainly by Mr. R. V. Wadsworth) give a good idea of the composition of the pulp. Analyses which the author and others have made of the liquid from the pulp show that it contains about 10 per cent. of reducing sugars (presumably dextrose and laevulose) and 2 per cent. of mucilage and pectin.

Cacao Sweatings

	From Trinidad			From Ceylon	
	0–18th hour	17th–18th hour	40th–42nd hour	From beans straight from pod	After 12 hours' fermentation

Colour	Light buff, cloudy	Deep yellow, cloudy	Buff, deeper than 1st, cloudy	Dirty yellow, cloudy	Dirty brownish yellow, cloudy
Pectin and mucilage	1·9%	2·1%	1·6%	—	—

The pulp and "sweatings" are obviously excellent media in which to grow yeast, and, later, acid-producing bacteria.

The cacao-pods are always broken, and the beans extracted, in the plantation, and the juicy beans are carried to the fermentation boxes, sometimes a considerable distance away. They are thus exposed

to any micro-organisms that may be in the air, as well as to those in the boxes. I examined cacao beans in Trinidad, as put in the box, and could find very few organisms. After 24 hours the pulp swarmed with yeast cells, but the numbers varied greatly in different parts of the box. It has been pointed out by Nicholls that a minute fruit fly (*Drosophila melanogaster*) assists materially in distributing yeasts and bacteria. After about 40 hours there were many budded yeasts, and after 60 hours the pulp contained great quantities of bacteria. Nicholls[5] states that there is no acetic acid, or other volatile acid, in the fresh fruits. The pulp of the bean as taken from the pod is acid, containing from 0·6—1·4 per cent. (estimated as acetic), and according to my observations the acidity of the pulp does not increase appreciably during the first 40 hours. In other words, acid-producing bacteria are not yet present in quantity. Observers have found a variety of yeasts and bacteria.

MICRO-ORGANISMS FOUND ON FERMENTING CACAO

Observer	Kind of cacao	Micro-organisms
Chittenden (1899)	Trinidad	(1) *Saccharomyces cerevisiæ* and probably *Penicillium glaucum*. (2) Lactic acid and possibly butyric acid bacteria.
Preyer (1901)	Ceylon	(1) *Saccharomyces theobromæ* (Preyer), resembles *S. ellipsoideus* (Hanson) and *S. membranæfaciens*. Length ·006 mm., diameter ·003 mm. (2) Bacilli and moulds (*Penicillium*).
Loew (1907)	Porto Rico	(1) *Saccharomyces ellipsoideus* with some *S. apiculatus*. (2) Acetic acid bacilli.
Nicholls (1912)	St. Lucia	*1st stage.*—Yeast, mainly "wild" yeasts (including *S. theobromæ*). *2nd stage.*—Acetic acid producing bacteria (bacilli and micrococci). *3rd stage.*—Putrefactive bacteria, and moulds.
Bainbridge and Davies (1912)	Jamaica	*1st stage.*—*S. apiculatus*, small quantities of *S. anomalus*. *2nd stage.*—Enormous development of true saccharomyces. *3rd stage.*—Acetic acid bacteria. *4th stage.*—Spore-bearing bacilli of *B. subtilis* type.
Lutz	..	*S. theobromæ*, *Sterigmatocystis niger*, *Pseudo-absida vulgaris*, and a new fungus, *Fusarium theobromæ* (Lutz).

It would appear from the above table that *S. cerevisæ*, *S. ellipsoideus*, and *S. theobromæ* have all given satisfactory cacao fermentations. Preyer and Nicholls have both emphasised the advantage of using a culture of the special yeast, *S. theobromæ*. In my experience the addition of yeast when the cacao is put in the box is an advantage—it saves waiting 24 hours whilst the yeast cells accidentally present multiply—but I have no evidence that there is any special merit in *S. theobromæ*. The addition of 1 pint of yeast obtained from a brewery started the fermentation earlier, and produced as good a cacao in one day less than the ordinary fermentation. A sample of tinned yeast, as sold to bakers, assisted the fermentation in the early stages, but did not produce quite so good an effect.

TEMPERATURES

It may be interesting to compare the temperatures which I obtained under a variety of conditions using the same cacao (mainly Trinidad Forastero).

TEMPERATURES OBSERVED IN VARIOUS SWEAT BOXES IN TRINIDAD

Quantity of beans 8-10 cwt. unless otherwise stated.

Beans turned after 16, 40, 64, 88 and 112 hours.

Curve 3 shows a normal fermentation of 10 cwt. of beans. The temperature in this case rises to 51° C. in 5 days, and then falls. Curve 5 shows a normal fermentation in a barrel (containing 3 cwt.) placed in a shed. This having relatively more area exposed rose more slowly, but being protected from the wind, gave good results. Curve 6 shows what happens if one attempts to ferment as little as ½ cwt. in a box, which is not protected from air-currents. The temperature rises only a few degrees, and the beans are only partially fermented. Curve 2 shows one of the experiments in which brewers' yeast was added. From the 24th-48th hour the temperature was at least 3° C. higher than usual, and at the end of the third day the beans were as advanced in appearance as the ordinary after four days. A similar advantage was obtained, as is indicated by Curve 1, by adding the "sweatings" (from beans which had been in the box 24 hours) to beans which had just been placed in the box. In order to obtain greater aeration perforated bamboo pipes were arranged horizontally through the mass of beans; the temperatures are shown in Curve 4.

I made a number of observations in Trinidad and Grenada of the temperature of fermenting cacao beans. The majority were in boxes which held about 8 cwt. of beans, but some held as much as 30 cwt. The beans were usually about 3 ft. deep. The averages are recorded below, together with certain related temperatures:—

TEMPERATURES OF CACAO FERMENTATION

Temperatures of a good cacao fermentation		Related temperatures
After 0 days	25° C.	
,, 1 day	30° C.	33° C. Cacao butter melts.
,, 2 days	37° C.	40° C. Action of yeast impaired. 42° C. Action of acetic acid bacteria (*B. Pasteurianus*, *B. Aceti* and *Mycoderma Vini*) and *B. Lactis Acidi* impaired. 44° C.–47° C. Cacao seed killed.
,, 3 days	47° C.	
,, 4 days	48° C.	
,, 5 days	49° C.	
,, 6 days	49° C.	50° C. Action of zymase ceases? 70–75° C. Cacao oxidase destroyed. Diastase destroyed.

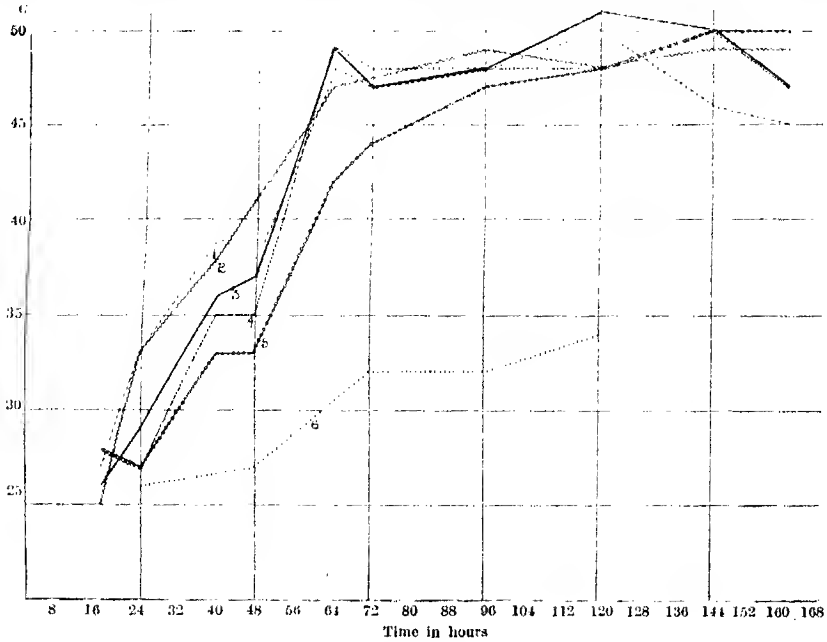
No one seems to have called attention to the very high temperatures which are maintained in cacao fermentation. It is well known that in the production of wine the action of the grape yeasts is impaired

above 40° C., and the temperatures favourable to cacao fermentation are those at which wine develops diseases. I certainly found some yeasts on the pulp, but after the fourth day the micro-organisms present were mainly non-motile rod-like bacteria, some isolated, others in pairs and chains.

Changes in the Pulp

The alcoholic and acetic fermentations break down the cells of the pulp, and the liquid they contain flows away. What one actually sees is that the pulp gradually loses its glutinous nature and finally becomes a thin coat of paste. It also changes colour. The first day it is white to pink; second day, pale pinkish-brown; third day, pinkish-brown; fourth day, light brown; fifth day, brown. This brown colour is due to oxidation of a tannin in presence of an oxidase, but whether the tannin was originally present in the pulp, or was acquired from the bean, I do not know. After the fifth day I examined the pulp under the microscope, and found that it contained a number of brownish-yellow spherical bodies, which I assumed to be yeasts stained by this brown colour.

The beans when put in have a delicate melon-like odour. After three days this has changed to a heavy, sharp, fragrant odour, such as might be given by a mixture of ethyl and amyl esters with a little acetic acid. Later, the odour suggests sour barm. Bainbridge and Davies[6] found amyl propionate, amyl acetate, and amyl butyrate in the essential oil of cacao. In relation to the presence of amyl butyrate, it may be mentioned that the production of butyric acid, because of its objectionable odour and taste, should be avoided. It is liable to be produced where the period of fermentation is long, and the aeration insufficient.



The "Sweatings"

The liquid portion of the pulp which flows away is slightly turbid, and of a pale brownish-yellow colour; the taste is faintly acid and sweet, the odour yeasty and apple-like. The addition of strong alkali causes it to gelatinise. The first "sweatings" are richest in sugars, the last richest in alcohol and acetic acid. This liquid is at present a nuisance to the planters, and at least ten million gallons must run to waste every year. Planters might with advantage use the first day's "sweatings" to pour over fresh cacao put in the box. It is evident that it could also be used to produce a drink resembling cider, which would contain, besides alcohol, small quantities of the stimulants, caffeine and theobromine. Hudson[5] has shown that it gives a mild, but strong, rose-coloured vinegar. To exploit these possibilities on a commercial scale the "sweatings" would have to be collected and treated at a central factory under scientific control.

(To be continued)

SAFEGUARDING OF INDUSTRIES ACT

Mr. Webb stated in the House of Commons that the Government had decided not to introduce legislation to extend the duration of the provisions of Part II of the Act, dealing with the making of Orders on the ground of depreciation of foreign currency. These provisions, and the duties imposed in accordance with them, will lapse on August 19.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 11 a.m.

A preliminary programme appears on this page.

In accordance with the provisions of by-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting: Dr. E. F. Armstrong, F.R.S., *President*; Mr. Julian L. Baker, Mr. C. S. Garland, Sir Max Muspratt, Bart., and Sir Wm. J. Pope, K.B.E., *Vice-Presidents*; Mr. John Allan, Prof. J. W. Hinchley, Dr. J. H. Paterson, and Mr. W. J. U. Woolcock, C.B.E., *Ordinary Members.*

Mr. W. J. U. Woolcock, C.B.E., has been nominated for election to the office of President under by-law 19; Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., have been nominated Vice-Presidents under by-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been re-elected Hon. Foreign Secretary.

Members are requested to nominate, on or before May 9 next, fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22.—An Ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if:—

(*a*) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the by-laws.

(*b*) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(*c*) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the by-laws.

(*d*) The nomination form is not received before or upon the day appointed therefor.

(*e*) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. Longstaff,
General Secretary

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

Wednesday, July 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. Presidential Address by E. Frankland Armstrong, D.Sc., F.R.S.; *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

Thursday, July 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*: Annual Dinner of the Society at the Midland Adelphi Hotel.

Friday, July 11. *Morning*: Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

Saturday, July 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

MEETING OF COUNCIL

The monthly meeting of Council was held on April 11, 1924, the President, Dr. E. F. Armstrong, F.R.S., in the Chair.

The President reported that the Société de Chimie Industrielle had invited delegates from the Society to attend the fourth Congress of Industrial Chemistry to be held at Bordeaux on June 15. It was agreed to ask any members who might be in Bordeaux at that time to attend as representatives of the Society.

The President gave further particulars regarding the scheme for "Chemistry House" which he had previously outlined, and after full discussion he was unanimously authorised to consult with the President of the Chemical Society and with any other interested Societies, including the Federal Council, with a view to at once carrying the Scheme into effect if it be found practicable.

Reports of various Committees were submitted, and 16 new members were elected:—Home 10; Overseas 6.

Mr. W. J. U. Woolcock, C.B.E., was nominated as President of the Society for the year 1924-25, and Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., were nominated as Vice-Presidents. Mr. Julian L. Baker was specially thanked for the valuable services he had rendered to the Society during the years he had been on the Council. Mr. E. V. Evans was re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., F.R.S., Hon. Foreign Secretary for 1924-25.

It was reported that Dr. Bjarne Johnsen will attend the annual meeting of the Society in Liverpool as an official delegate of the American Section.

Dr. E. F. Armstrong, F.R.S., was nominated a representative of the Society to attend the Centenary Celebrations of the Franklin Institute to be held in Philadelphia, Pa., on September 17, 1924. It was also agreed to ask the Chairman of the American Section to act as another representative of the Society.

It was agreed on the application of Sir I. Gollancz, on behalf of the British Academy Committee, to make good as far as possible any loss that the Tokyo Imperial University Library sustained in the recent earthquake in respect of the Society's publications.

The next meeting will be held on Friday, May 9, 1924, at 2.30 p.m.

MANCHESTER SECTION

The annual meeting was held on April 4, Dr. H. Levinstein presiding. The whole of the committee and officers of the Section were re-elected, there being no occasion for a ballot.

The honorary secretary (Mr. L. Guy Radcliffe) read his report of the transactions of the Section for 1923-1924. He said that the numerical strength of the Section was 506, as against 510 at this time last year. The number of papers arranged for, or read at the eight meetings of the session, was twelve and a joint meeting had been held with the Institute of Chemistry, the Society of Dyers and Colourists, and the Manchester Literary and Philosophical Society. On December 7 there was an innovation in the shape of a joint meeting between the Manchester Section and the Institution of the Rubber Industry, whilst on February 22 there was a joint meeting with the Liverpool Section. On March 7 the Section was fortunate in receiving the promised visit of Prof. F. Gowland Hopkins, who delivered a most delightful and philosophic address to a large and appreciative audience. At the time of presenting this report two meetings remained to be held, and for the annual meeting there was the paper from Prof. F. L. Pyman, whilst, at the last meeting in May, Dr. Arnold Renshaw had promised to read a paper on "Insulin," and there will probably be two short communications from Mr. J. Miller on "A Recent Bleaching Agent for Flour" and "The Detection of Persulphate in Flour." In concluding the report, reference was made to the death of Mr. William Thompson, a former chairman of the Section, and one whose interest in the Society commenced with the birth of the Society and ceased only with his death. His loss was much felt.

Prof. Pyman proposed and Mr. John Allan seconded, the adoption of the report, and the motion was carried unanimously. A very hearty vote of thanks was also accorded the hon. sec. for his services to the Section during the past year. The usual monthly meeting was then held.

Prof. F. L. Pyman, D.Sc., F.R.S., in reading his paper on "The Tautomerism of Amidines," stated that von Pechman found that only one amidine of the general formula

$$R.C.\begin{cases}NX\\NHY\end{cases} \quad \text{or} \quad R.C.\begin{cases}NHX\\NY\end{cases}$$

could be prepared, and that the behaviour of such compounds on alkylation with alkyl salts depended upon the relative characters of X and Y. Where these were similar, *e.g.*, phenyl and tolyl, he obtained on alkylation a mixture of the isomeric alkyl derivatives, but where they differed considerably in character (*e.g.*, phenyl and methyl) he was only able to isolate a single alkyl derivative. In the course of the present series of investigations, it had been shown that there was no qualitative difference between the two cases where X and Y were similar and where they differed in character. In both cases a mixture of the two possible isomeric alkyl derivatives resulted, the relative yields of the two being largely influenced by the relative characters of X and Y. In the earlier papers (*Trans. Chem. Soc.*, 1923, vol. 123, pp. 367, 3359) the behaviour of open-chain amidines was examined, and the present communication (with C. E. Hazeldine and the late John Winchester), recorded the results of treating 4 (or 5) nitroglyoxaline and 4 (or 5) phenylglyoxaline with dimethyl sulphate. It was found that the alkylation of 4 (or 5) nitroglyoxaline in this way gave 5-nitro-1-methylglyoxaline as the main product of the reaction, with mere traces of the isomeric 4-nitro-1-methylglyoxaline, and that all of a number of compounds containing the nitro group in the 4 (or 5) positions, with various other groups in the 5 (or 4) positions, behaved similarly, the main product being always the isomerdine with NO_2 : Me- 5:1. According to unpublished experiments (with I. E. Balaban) the bromine atom had an influence similar to but not so powerful as that of the nitro-group, whilst the known results of alkylating xanthines showed that the carbonyl group was similarly 5 : 1-derivative. The influence of the phenyl group, however, was different, for the alkylation of 4 (or 5)-phenylglyoxaline under similar conditions gave, as the main product of the reaction, 4-phenyl-1-methylglyoxaline together with a small quantity of 5-phenyl-1-methylglyoxaline. The methods of determining the orientation of the methylated nitro- and phenylglyoxalines were described.

SOCIETY OF PUBLIC ANALYSTS

A meeting was held on April 2, Mr. G. Rudd Thompson in the chair and four papers were read.

A Report on the World's Dairy Congress held at Washington, U.S.A., was given by J. Golding, D.S.O., who also described visits to laboratories, Universities, etc., in New York, Washington, Ithaca, Guelph, etc.

Messrs. L. H. Lampitt, D.Sc., E. B. Hughes, B.Sc., and M. Bogod, B.Sc., read a paper on "The Routine Examination of Dairy Products with Special Reference to the Mojonnier Tester" for the determination of total solids of milk. The tester consists of a hot plate on which the milk is evaporated in an aluminium dish, and an electrically heated and thermostatically controlled vacuum oven in which drying is completed, the dish being cooled off in a water-cooled desiccator. The time for a complete determination of total solids in milk is 21 minutes. The Mojonnier method for the determination of fat is a modified Röse-Gottlieb method. The extraction is carried out in a specially shaped flask, which can be shaken after adding each reagent, and then centrifuged.

The ethereal layer is decanted into an aluminium dish, evaporated on a hot plate, dried in a vacuum oven, and cooled in the desiccator. The time for a complete determination of fat is 30 minutes, or for total solids and fat together 38 minutes. Typical results were shown for these determinations on various milk products. An application of the Gerber method to the determination of fat in milk powders was advocated.

"Experiments on the Absorption of Copper following the Consumption of Vegetables containing Copper Sulphate," were described in a paper by Prof. J. C. Drummond, D.Sc., Miss M. G. Palmer, B.Sc., Miss D. E. Wright, B.Sc. Metabolism experiments have been made on rats maintained on diets containing a high proportion of peas containing added copper. As recorded by previous observers, most of this copper is not absorbed but is excreted by the alimentary tract. Definite evidence was obtained that some small proportion of the copper may be absorbed into the blood. This absorbed copper may be in part retained for a time by the liver, and is excreted by the kidneys. Rats maintained for two to three months on diets containing a high proportion of copper-peas showed normal growth and health. Close examination of the tissues at the end of the experiment showed no abnormality which could be attributed to the copper absorbed from the food.

A paper on "An Attempt to extend Mitchell's Colorimetric Method to the Catechol Tannins," was presented by Phyllis H. Price, B.Sc. (work done under the Analytical Research Scheme). Mitchell's ferrous tartrate reagent can be used for the colorimetric comparison of (1) catechol with catechol; (2) protocatechuic acid with protocatechuic acid; and (3) catechin with catechin, but the method does not give satisfactory results for the comparison of these substances with one another. The ration between the colorimetric results is not a molecular one, as observed by Mitchell for pyrogallol and gallic acid, where the carboxyl group acts as a diluent. Catechol tannins, unlike pyrogallol tannins, are precipitated by the combined action of the reagent and quinine hydrochloride or cinchonine sulphate, and this behaviour prohibits the application of the method to catechol tannins. A series of experiments has shown that in order to give the violet coloration with the reagent a substance must contain two hydroxyl groups in the ortho position.

CORRESPONDENCE

INTERNATIONAL SCIENTIFIC RELATIONS

Sir,—I have read the letter of Dr. Fritsche and your comments with very great interest. You may be surprised to know that I do not consider the letter an insuperable obstacle to internationa scientific relations. Dr. Fritsche gives a frank honest statement of the German point of view about questions on which Germans and the Allies cannot be expected to reach common ground for a generation at least—if we continue the present non-intercourse, it may be much longer than that. For a long time Frenchmen and Belgians will continue to believe that German "frightfulness" in the occupied regions was excessive—they saw it with their own eyes while most Germans knew of it only through censored reports. Germans will continue to believe that the conduct of their soldiers was justified by occasional acts of guerilla warfare by the Belgians and as a precautionary measure. The Allies will continue to believe that the war was one of aggression on the part of Germany—Germans will continue to believe that the determination of England to maintain her commercial and naval supremacy and the desire of France for "Revanche" and for the recovery of Alsace and Lorraine were the chief causes of the war —also that the agreements between England, France and Belgium for the defence of the last were a violation of neutrality and a partial justification for the German invasion.

When a war is once started it is easy to rally any people to the patriotic support of their country, and the rank and file of any people will believe that their country is right and the other wrong and *they will continue to believe this after the close of the war.* We cannot hope to change this fundamental fact.

In spite of the above conditions, which we must clearly recognise, I believe that the better class of *both Frenchmen and Germans* desire a permanent peace and that a "rapprochement" is possible. It is not very safe to prophesy, but I believe that the report of the "Experts" will be accepted by France and Germany. On the side of France it will give her the support of the Allies once more and will give her a larger sum in "Reparations" than she can hope to get in any other way. Without its acceptance it would probably be impossible to prevent the franc from going the way of the mark. It was dangerously near to doing that less than a month ago. In Germany, the refusal to accept will prevent any international loans and must soon lead to a financial chaos more disastrous than that through which she has passed.

The acceptance of the report must soon bring a *permanent* settlement of the "Reparations" question. Poincaré cannot continue to hold an indefinite sum hanging over Germany. Personally, I believe that the sum necessary to restore the "losses to the civilian populations," not including pensions or the costs of the armies of occupation, is about the limit of what the Allies can hope to get. Practically, if the amount could be put squarely on that basis, Germany would be compelled to acknowledge that that is in strict, or even in generous accord with the

terms to which she agreed after they were announced to her by President Wilson on November 5, 1918, and it should be possible to carry on a campaign on that basis *both in Germany and France.*

If this practical "rapprochement" is realised, as I hope it may be, I think that the intellectual leaders of England, France and Germany should lead in the movement for peace and should meet again on the basis of common intellectual and scientific interests, agreeing to avoid the discussion of political questions about which there is a difference of opinion. If we wait for a radical change of opinion *on either side,* we shall hinder rather than hasten that softening of differences which we desire. Scientific men can never be coerced to a change of heart in that way.—I am, Sir, etc.,

W. A. NOYES

Paris
April 8, 1924

QUALIFIED OR UNQUALIFIED?

Sir,—I have been both interested in and amused at the various expressions of opinion regarding the chemist and the Institute of Chemistry.

Some opinions have been sane and thoughtful, others, particularly that of Mr. Claremont, have been ridiculous. How else can one describe such a statement that only members of the Institute are qualified chemists?

Suppose such an attitude be followed to its logical conclusion, what may happen? Obviously if chemists who are not members of the Institute unite to form an opposing society, it would be quite in order for them to say only members of their own society were qualified chemists. Similarly people may form themselves into a society and say black is white!

I quite agree with Mr. Claremont that chemists should be properly qualified, but I do not agree with him or the Institute that the only way of qualifying is to attend a college recognised by the Institute.

Presumably the Institute would not consider me a qualified chemist, and consequently would like to oust me from my post, although I attended a technical school for several years and passed a considerable number of examinations in chemistry and allied subjects.

Unfortunately at the time I did not know that hydrogen, for example, was not hydrogen if prepared at an unrecognised college!

If the Institute would open its doors to the qualified chemist without asking how he became qualified, it would go much further towards attaining its objects in a year or two than it has previously during the whole of its existence.

But, no! a man may arrive at Minerva's Temple, but if the Institute is the commissionaire at the time, he will not be admitted to her presence unless he arrives in a Rolls-Royce, and yet it is a universal practice to honour a man who succeeds in the face of difficulties.

The fact is, the Institute is a very exclusive trade union, but differs from other trade unions in that it prefers to spurn a man rather than extend a hand of comradeship.

Between the Institute, on the one hand, and the employers, who to keep wages down fill their laboratories with about 90% of apprentices (if I may call them such), on the other, the position of the chemist —qualified or unqualified—is not an enviable one. —I am, Sir, etc.,

"IRON"

A DESIGNATION FOR MEMBERS OF THE CHEMICAL PROFESSION

Sir,—Mr. C. L. Claremont's letter on the Profession of Chemistry in the issue of March 7, revives a discussion which flourished in your columns last year and terminated to my regret without any reference to a proposal made (though as yet not adopted) in Canada, which would avoid the issue with the pharmaceutical profession. Is it not futile to demand that the members of that profession abandon a title, which as Mr. Claremont points out, is popularly associated with their calling and to which they have historical and legal claims? To students of chemistry the coining of words is a familiar practice. Why not coin one to designate the man qualified to practise the profession of chemistry whether as an investigator, teacher, analyst, consultant or manufacturer? The term suggested in Canada (by Mr. J. A. Macdonald Dawson of Vancouver, B.C.) is "Chemor." What objection can be taken to it?—I am, Sir, etc.,

J. F. SNELL
Professor of Chemistry

Macdonald College, Que.
March 28, 1924

THE EPILATION OF SKINS

Sir,—I have been taken to task for not answering Mr. Wood's hint about the possibility of the inhibition action of the salt in my guinea-pig experiment. Salt cannot inhibit an enzyme that is no longer there, besides, normal saline solution contains the same strength of salt as normal blood which certainly does not inhibit its own enzymes.—I am, Sir, etc.,

H. C. ROSS

113, Mount Pleasant
Liverpool

AN EXHIBITION OF CHEMICAL PRODUCTS

Sir,—It has doubtless been suggested before, though I do not remember having seen it, that one way of popularising chemistry and bringing to the notice of the public some concrete knowledge thereof, would be to have a permanent exhibition of chemical products, more or less on the lines of the Mineralogical Gallery in the British Museum of Natural History. There are very many substances, both organic and inorganic, which would form most attractive and interesting exhibits—finely crystallised masses of various salts, dyestuffs, specimens of trinitrotoluene and other explosives (in suitable quantities!) of the various metals, etc., etc. I remember such exhibits on a comparatively small scale at some of the Exhibitions in past years, and the Chemical Exhibits at Wembley this year (or some of them) might well form a nucleus for such a gallery.

Accommodation would doubtless be the chief difficulty; logically such exhibits should presumably find a home at the Victoria and Albert Museum, though there is, I fear, little chance of space being available there. Perhaps, however, room could be provided, at any rate quasi-permanently, at Wembley after the present Exhibition is over?

Later the more strictly scientific side of the proposal could be extended with the ultimate aim of having a complete collection of all the innumerable substances known to chemistry, so that in time it should become customary for the accounts of the preparation of new bodies presented to the Chemical or other Society to be accompanied by samples thereof for the National Collection, in the same way as a copy of every book published is deposited in the British Museum Library.—I am, Sir, etc.,

C. A. Silberrad

A CORRECTION

We regret that an error was made in publishing the letter from Prof. W. Bone, F.R.S., in our last week's issue. The letter was intended solely for the Editor's private information and not for publication. In the chance that a misunderstanding might arise, we are glad to publish this note.

PERSONAL AND OTHER NOTES

Chemistry House

At a meeting of certain Members of the Federal Council, and of the Chemical Industry Club Committee, held at the Club, on Friday, March 14, 1924, the following Resolution was unanimously agreed to:—

We are of opinion that the best interests of academic, technical and manufacturing chemical science will be ultimately best served by the immediate establishment of a Chemistry House, on a scale involving an outlay of, say, £30,000. We are of opinion that the scheme just outlined should be regarded merely as a basis of a larger scheme for providing adequate accommodation for all the organisations representing the corporate interests of academic, technical and manufacturing chemistry.

At the meeting of the Chemical Industry Club, held on April 14, it was resolved unanimously:—

1. That this meeting of the Members of the Chemical Industry Club, having heard the action taken by the Executive Committee on the subject of the establishment of Chemistry House to date, approves such action.

2. The Chemical Industry Club will support any sound scheme for the establishment of Chemistry House, whether this necessitates the merging of the Club in the scheme or not, but is strongly of opinion that such scheme should be approved by the Members of the constituent and associate bodies forming the Federal Council.

FORTHCOMING EVENTS

Apr. 22 to 24. International Cement Congress, Olympia, London, under the ægis of the Institution of Structural Engineers.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5¼d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide	4s. per lb.
Carbon Bisulphide	£24—£26 10s. per ton according to quantity.

Carbon Black ..	.. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride	.. £56 per ton, drums free.
Chromium Oxide	.. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black ..	.. 40s. per cwt., barrels free.
Lead Hyposulphite	.. 7½d. per lb.
Lithopone ..	.. £22 10s. per ton.
Mineral Rubber "Rubpron"	.. £15 10s. per ton f.o.r. London.
Sulphur	.. £10—£12 per ton, according to quality.
Thiocarbanilide ..	.. 2s. 9d. per lb.
Vermilion, pale or deep	.. 3s. 4d.—3s. 6d. per lb.
Zinc Sulphide ..	.. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—	
Brown	.. £14 10s. per ton d/d. Demand active.
Grey	.. £21 per ton.
Liquor	.. 9d. per gall. 32° Tw.
Charcoal	.. £7 5s.—£9 10s. per ton, according to grade and locality. Market steady.
Iron Liquor ..	.. 1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor ..	.. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote ..	.. 2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible ..	.. 5s. per gall. 60% O.P. Dull market.
Solvent ..	.. 5s. per gall. 40% O.P. Dull market.
Wood Tar ..	.. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead	.. £47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—	
Crystals ..	.. 7¾d. per lb. Only limited inquiry.
Crude 60's ..	.. 2s.—2s. 3d. per gall. Market not so good.
Acid Cresylic, 97/99	.. 1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95% ..	.. 1s. 10d.—2s. per gall. Steady demand.
Dark	.. 1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	.. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained ..	.. 10d.—11d. per gall. Very quiet.
Unstrained ..	.. 8½d.—9d. per gall.
Benzole—	
Crude 65's ..	.. 10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	.. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure ..	.. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% ..	.. 1s. 4½d.—1s. 7d. per gall.
Pure ..	.. 1s. 8d.—1s. 11d. per gall.
Xylol coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	.. 10d. per gall. Few inquiries.
Middle Oil .. / Heavy .. .. / Standard Specification	7½d.—8d. per gall. according to grade and district. Market again weaker.
Naphtha—	
Crude	.. 8d.—9d. per gall. Better demand. Prices show upward tendency.
Solvent 90/160	.. 1s. 2d.—1s. 5d. Better demand. Prices show upward tendency.
Solvent 90/190	.. 1s. 2d.—1s. 3d. Better demand. Prices show upward tendency.
Naphthalene Crude—	
Drained Creosote Salts	£6—£7 10s. Demand not so good.
Whizzed or hot pressed	£9 10s.—£12 per ton. Not much inquiry.
Naphthalene—	
Crystals and Flaked	.. £17—£18 per ton.
Pitch, medium soft	.. 52s. 6d.—57s. 6d. per ton. Market steadier.
Pyridine—90/140	.. 22s. per gall. Demand well maintained. Price again advanced.
Heavy	.. 11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	.. 1s. 6d. per lb.
Acid H.	.. 4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 9d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 4d. per lb. Steady demand.
Acid Sulphanilic	.. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	.. 1s. per lb. d/d.
Aniline Oil ..	.. 7¾d.—8½d. per lb. naked at works.
Aniline Salts ..	.. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 3d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £75 per ton.
Diethylaniline ..	.. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline ..	.. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluence—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 3s. 2d. per lb. d/d.
Monochlorbenzol ..	.. £63 per ton.
α Naphthol ..	.. 2s. 5d. per lb. d/d.
β Naphthol ..	.. 1s. 1d. per lb. d/d.
α-Naphthylamine	.. 1s. 4½d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline ..	.. 5s. 3d. per lb. d/d.
p-Nitraniline ..	.. 2s. 4d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 11¾d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.

m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is lifeless, values remaining at a low level.

Acid, Acetic 80% B.P.	£48 per ton. Market easier.
Acid, Acetyl Salicylic	3s. 5d.—3s. 9d. per lb. Easier.
Acid, Benzoic	Commercial acid 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. lb.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	Prices quoted from 2s. 3d. per lb. down to 1s. 9d. for ton lots. Market rather weak.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 6d. per lb. for quantity. Very weak.
Amidopyrin	13s. 6d. per lb.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. 3d. per lb. Firmer.
Bismuth Salts	A steady market. Prices according to quantity :
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market very firm and advancing. Heavy increase in price of bromine.
Potassium	9½d.—10½d. per lb.
Sodium	9½d.—10½d. „
Ammonium	10½d.—1s. „
Calcium Lactate	Prices vary over a wide range. Good English make can be had from 1s. 7d. to 2s. 3d. per lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. per lb. Little demand.
Guaiacol Carbonate	12s. per lb. for cwt. lots. A cheaper market.
Hexamine	3s. 6d.—3s. 9d. per lb. for foreign makes. Weaker. Without much inquiry. Large stocks.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 3d. per lb. Foreign make.
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	70s. Strong upward movement due to disappointing Japanese crop.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Very much firmer in view of the rise in the price of quicksilver. Prices have been advanced by 6d. per lb.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. „
White precip.	4s. 7d.—4s. 8d. „
Calomel	3s. 11d.—4s. „
Methyl Salicylate	2s. 3d.—2s. 9d. per lb. for carboys.
Methyl Sulphonal	24s. per lb. neglected.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 4d.—1s. 7d. per lb. in free bottles and cases.
Phenacetin	6s. 3d.—6s. 9d. per lb.
Phenazone	8s. per lb. for cwt. lots. Spot prices much lower than forward offers. Firmer tendency.
Phenolphthalein	7s.—7s. 6d. per lb. Firm.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal	8¾d.—9d. per lb. carriage paid. English make.
Commercial	8d.—8½d. per lb. carriage paid. English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Salol	4s. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—	
Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate	Market weak. Powder 2s. 4d.—2s. 9d. per lb. Crystal at 2s. 6d.—2s. 10d. per lb. Flake 2s. 10d.—3s. 4d. per lb.

Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	.. 18s. 6d. per lb.
Tartar Emetic ..	.. 1s. 4d. per lb.
Thymol	.. 13s. 6d.—15s. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.	
Aubepine	.. 13s. 6d. ,,	
Amyl Acetate ..	.. 2s. 9d. ,,	
Amyl Butyrate ..	.. 7s. 3d. ,,	
Amyl Salicylate ..	.. 3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d. ,,	
Benzaldehyde free from Chlorine ..	.. 3s. 6d. ,,	
Benzyl Benzoate	.. 3s. 6d. ,,	
Cinnamic Aldehyde Natural	.. 15s. 6d. ,,	
Coumarin ..	.. 20s. ,,	
Citronellol ..	.. 16s. ,,	
Citral	.. 10s. ,,	
Ethyl Cinnamate	.. 15s. ,,	
Ethyl Phthalate ..	.. 3s. 9d. ,,	
Eugenol	.. 11s. ,,	
Geraniol (Palmarosa)	.. 35s. ,,	
Geraniol	.. 11s.—18s. 6d. per lb.	
Heliotropine ..	.. 8s. 3d. per lb.	
Iso Eugenol ..	.. 15s. 9d. ,,	
Linalol ex Bois de Rose ..	32s. 6d. ,,	Very much dearer.
Linalyl Acetate ..	.. 32s. 6d. ,,	Very much dearer.
Methyl Anthranilate	.. 9s. 6d. ,,	
Methyl Benzoate	.. 6s. ,,	
Musk Ambrette ..	.. 52s. 6d. ,,	
Musk Xylol ..	.. 19s. ,,	
Nerolin	.. 4s. ,,	
Phenyl Ethyl Acetate ..	12s. 6d. ,,	
Phenyl Ethyl Alcohol ..	16s. ,,	
Rhodinol	.. 57s. 6d. ,,	
Safrol	.. 1s. 10d. ,,	
Terpineol	.. 2s. 9d. ,,	
Vanillin	.. 25s. 3d.—26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 15s. 6d. per lb.
Anise Oil	.. 3s. per lb. Firmer market forward.
Bergamot Oil ..	.. 18s. 6d. per lb.
Bourbon Geranium Oil	.. 35s. ,,
Camphor Oil ..	.. 75s. per cwt.
Cananga Oil, Java	.. 9s. 9d. per lb.
Cinnamon Oil, Leaf	.. 6½d. per oz.
Cassia Oil, 80/85%	.. 9s. 3d. per lb.
Citronella Oil—	
Java 85/90% ..	.. 5s. 3d. ,,
Ceylon	.. 3s. 9d. ,,
Clove Oil	.. 8s. 4½d. ,,
Eucalyptus Oil 70/75% ..	2s. 3d. per lb.
Lavender Oil—	
French 38/40% Esters	26s. per lb.
Lemon Oil	.. 3s 4d. ,,
Lemongrass Oil ..	.. 2¾d. per oz.
Orange Oil, Sweet	.. 13s. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 27s. 6d. per oz.
Anatolian ..	.. 23s. 0d. per oz.
Palma Rosa Oil ..	.. 19s. per lb. Very short supply.
Peppermint Oil—	
Wayne County	.. 21s. 9d. per lb. Again advanced.
Japanese ..	.. 20s. per lb. but very little being offered.
Petitgrain Oil ..	.. 10s. per lb.
Sandal Wood Oil—	
Mysore	.. 25s. per lb.
Australian ..	.. 21s. per lb.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*British India*: Aluminium ingots (The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *Canada*: Cast iron pipes (13457/E.D./E.C./2).); Zinc dross and zinc ashes (Canadian Government Trade Commissioner's Office, 73, Basinghall Street, London, E.C. 2.); *Chile*: Copper, cast iron, insulators (9617/F.L./G.C./2.); *Cuba*: Hardware, glassware, silverware, (411); *Egypt*: Tin solder (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W. 1.); Ref. Muh. 1924/19/5.; *France*: Maritime materials (403); Copra, ground nuts, copper sulphate, sugar, (405); *Italy*: Leather (407); *Peru*: Glassware, surgical instruments, chemicals (412).

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, APRIL 25, 1924 No. 17

EDITORIAL

THE letter from Prof. Noyes which we published in last week's issue carefully avoids discussion of one or two interesting ethical questions. His letter is on the whole a plea for chemists of all nations to forget the past and live in the future in amity with each other. If the Germans believe that this nation and three or four others combined in the summer of 1914 to crush an innocent Germany is it right that they should forget or pretend to forget this circumstance? Would it be right for the Belgians to wipe the slate in so far as the German invasion of Belgium is concerned? Could such an idea be anything except a piece of hypocrisy? What is the proper and high-minded attitude for Belgians, whether chemists or not, to adopt towards the Germans who claim that their treatment of Belgium was well deserved? Perhaps it is suggested that the ideal course is for the Belgians to say to the Germans "What we have heard about Dinant and Louvain and some other places is doubtless much exaggerated; your invasion of our country was more an error of judgment than a crime; send two or three of your distinguished chemists to lecture to us in Brussels as a token of our goodwill." We are not experts on ethics either national or international, and we are not clear whether if Belgium or France take up an attitude of refusal to be friendly with Germans who justify their conduct, we ought to blame them or applaud them. The point is not a mere academic one, it is of some consequence for the future. If some day, twenty or fifty years hence, the United States of America, or France, or Great Britain copies, with the improvements which that interval of time suggests, the conduct of Germany during the late war, is it better that the other nations of the world should on the conclusion of peace invite the belligerents to shake hands all round or should they show their disapprobation in any way?

* * *

On a pure point of morality if country A guarantees the integrity of country B and afterwards invades country B, what attitude should the inhabitants of country B take up when country A has been pushed out? The Germans, it seems, justify their actions in Belgium and would repeat them in similar circumstances. If the Belgians now offer to the Germans the right hand of good fellowship are we to conclude that they are men of noble dispositions or that they would be fit inmates of an asylum? We have met with people who consider the German treatment of Belgium to be a shocking crime unworthy of any civilised nation. We do not know whether Prof. Noyes thinks otherwise, but what advice does he offer to those who hold such an opinion? Are they to pretend they are mistaken? Are they to try and forget the evidence, which, when it was fresh in their minds, drove them to such an opinion? Are they to assume in spite of it that those who a few years ago behaved in that manner to Belgium are now milder in manners and gentler in their ways? The German men of science, according to Dr. Fritzsche, are satisfied that the Germans were then mild and gentle enough. We suppose our own opinions, those of us who were grown up in 1914 and capable of understanding what was done, are of no account. If we still feel any indignation it should be with Italy and the United States, we imagine, for obstructing the Germans in their mildness and gentleness. Before we lose our heads in sophistry and illusion let us look at this extreme case in cold blood and consider what is just and not what is expedient. Let us admit this is an extreme case; let us admit that the German accounts were, as Prof. Noyes puts it,

highly censored; the facts remain, *magna est veritas*; the Belgians know what happened, we in this country have a pretty shrewd idea. Is it wise or just or desirable that we who know less than they should say to the Belgians, "Forget the past"? Why should they forget it? You might as well ask a chemist to forget that picric acid is explosive or that sulphuric acid will dissolve zinc. We would like to ask Prof. Noyes whether he thinks he has enough evidence to justify him in having any definite opinion about Germany's treatment of Belgium. We will not ask him what his opinion is. If he has no definite opinion perhaps he might investigate such evidence as there is and find out as a scientific man what the essential truth is. If he has a definite opinion we feel sure that the opinion of the Belgians, whether it agrees with Prof. Noyes' or not, will be much more definite. We think that Prof. Noyes is doing a good work in trying to promote a better feeling between chemists of all nations; we wish him every success, and we think that any future good feeling will be founded on a knowledge of the truth and not on a pretended ignorance of essential facts. Let us build on realities whether we are building friendship or knowledge. Is the German treatment of Belgium merely a political question about which there is a difference of opinion? Is there no question of morality, of justice, of humanity? Or is the whole difference of opinion comparable with a divergence as to whether ammonium hydroxide does or does not exist in solution? Let us stick to realities; we know all the essential facts about the invasion and occupation of Belgium by the Germans—there is no real dispute about the essentials, the Governments of Belgium, Germany and some other countries knew the truth and published a great deal of it. The rulers of Germany know as well as we do that on the whole it was a shocking business. The German Chancellor himself and many others knew it was in 1914; so long as the German men of science approve of the invasion and occupation so long will it be ineffectual for any one to suggest to the Belgian chemists that they shall sit down peacefully to lunch with the German chemists. So far as the Belgians are concerned let us wait until they have rather more confidence than they now have in the friendly intentions of the Germans. When the Belgians are ready to forgive let us rejoice; let us not urge or advise them to reach this state of mind.

* * *

We publish in this issue a review by E. F. A., on Osborne's book on "The Vegetable Proteins." Knowledge of the compounds contained in plants and of the chemical processes which go on in plants has increased enormously during recent years. Many of us can recollect the time when the botanist regarded chlorophyll, starch and cellulose as compounds of a degree of complexity far beyond the reach of the human mind. At that time but little was known of the chemistry of plant life beyond the fact that plants absorbed carbon dioxide and evolved oxygen. Bit by bit facts have been accumulated, new compounds isolated and their structures determined. We have now an accurate knowledge of the many terpenes and camphors produced by plants, of many of their scents and colouring matters. The various kinds of chlorophyll have been separated and distinguished, the occurrence of hydrocarbons such as pentane and carotin has been studied with care. Starch, inulin, cellulose and ligno-celluloses are no longer mere names. The alkaloids have been synthetically prepared or so closely investigated that their constitution is no longer a matter of speculation. Enzymes have furnished a copious literature and those monographs on Biochemistry which deal with plant life contain a mass of information of considerable scientific value. The sugars and other carbohydrates have been studied so much that their chemistry may now be considered as almost worked out. How agreeable it would be to have an account of botanical chemistry written in such a way that a retired solicitor or a white-lead manufacturer, whose curiosity is not entirely extinguished, could sit down in his garden under his mulberry tree and read it, every now and then getting up to admire the *Primula farinosa* which this imaginary individual has reared with such care and comparing its waxy covering with the inadequate description of it given in print!

* * *

We are informed that the American Chemical Society has arranged with the National Research Council for the publication by the Williams and Wilkins Company of Baltimore, of a new venture to be called *Chemical Reviews*, consisting of a yearly volume of about five hundred pages to be issued in four numbers in January, April, July and October in each year. The Editor-in-chief is Professor W. A. Noyes, and arrangements have been made with the Chemical Society here to give Fellows the advantage of having the American Chemical Society journals and *Chemical Reviews* at the same price as the Members of the American Chemical Society. This very friendly arrangement will be much appreciated. The price of *Chemical Reviews* is four dollars a year to such favoured persons and the list of contributions to the first two numbers suggests that the new journal will be an attractive one. The first number will contain papers by T. W. Richards on "Atomic Weights and Isotopes," by J. C. Irvine on "The Constitution of Polysaccharides," by F. G. Donnan on "The Theory of Membrane Equilibria," by M. Gomberg on "Organic Radicals." The second number will contain papers by G. N. Lewis on "The Quantum Theory of Chemical Affinity," by A. F. Holleman on "Some Factors Influencing Substitution in the Benzene Ring," by T. Svedberg on "Some Recent Advances in the Field of Colloids," by G. Urbain on "Twenty-five Years of Research on the Yttrium Earths," and by A. A. Noyes on "The Systematic Detection of the Rarer Chemical Elements." *Chemical Reviews* will not be confined to articles on purely theoretical topics but will also accept articles of suitable nature on industrial topics. We hope to deal with this subject at a later date when we have fuller information.

British Empire Exhibition

Wembley, April—October, 1924

The British Empire Exhibition at Wembley is already very good and by the time these notes appear in print it will be even better. It has been so much advertised and so much discussed, in Parliament, in the Association of British Chemical Manufacturers, in the Society of Chemical Industry, in this *Journal* and in the daily newspapers that already many of us are a little prejudiced against it. But let us consider the matter in a really scientific spirit. The Exhibition is to illustrate the British Empire, perhaps no unworthy or inadequate topic; it will give us oracular demonstration, as Mr. Caleb Trotter called it, of India, Ceylon, Burma, Malaya, Hong-Kong and other places with architecture distinctive of each country and something to illustrate to us the natural and artificial products appertaining thereto. The buildings in the Exhibition representing the countries we have mentioned are alone well worth a journey from Manchester, Glasgow or Leeds to Wembley. To begin with these buildings are of unusual styles and are beautiful. The architects who have designed them had good taste; the craftsmen who assisted in their construction were skilled in their crafts, the artists who have adorned these buildings with friezes and frescoes have given the visitors real pleasure. There is a high standard about all these buildings, they do not look like Exhibition structures, they look like the real things and no doubt but for the expense they would have been. That ingenious philosopher, Dr. G. Blas, said "real virtue is a very expensive article; plated goods look just as well and are within the reach of all purchasers."

There is no doubt that the British Empire Exhibition has every right to be as imposing a landmark as was the 1851 Exhibition. Whether it will be is another question; the skirts of happy chance and the law of probabilities discussed gravely in a recent article in these pages affect this problem. But as the 1851 Exhibition will for ever, as "Q" put it, be associated with popular science, crochet antimacassars, corkscrew curls and prunella boots, so the Exhibition of 1924 will be typical of art, ideas, fashions and hopes which subsequent generations will scoff at. What will our grandchildren think of the Glasgow girls with their knee-breeches, bobbed hair and gaspers, who from coigns of vantage have left monuments of Georgian Art? What will they think of present day politics, present day literature and present day journalism? How few of us journalists have enough talents to keep our literary reputations alive so long as we ourselves live!

Wembley is obviously great enough and good enough to mark an epoch and this must be the excuse for trying to convey to the readers of this article the sort of impression made by a visit to the Exhibition. After seeing half-a-dozen typical buildings you realise that Wembley is far, far better than you had any right to expect and then you will wander, finding everywhere fresh objects of interest. Such sights again cannot be found, in any place on English ground, be it at wake or fair. Although the ground is English there is an obvious Scots accent attached to many of those who have been engaged in the construction of this Exhibition. It might be worth while some day to give Sir Robert M'Alpine a free hand to rebuild Airdrie and other towns in the purlieus of Glasgow! We cannot keep closely to our topic nor do we think any visitor who possesses a soul will steer a straight course when he sets foot in the Exhibition. Surely the walled city of the Gold Coast will drag him from his path or Australia or New Zealand or Canada or Newfoundland. The brooks and streams, the lakes, the gardens, the colonnades, the Stadium, the ever-moving railway, the water-chutes and other amusements will be as Sirens attracting all except a small remnant; duty will bind a certain number of qualified chemists with chains and unqualified with links of iron. There are upwards of fifty restaurants and cafés, bands giving music of all degrees from the austere tom-tom or the soulful ram's horn to the most exponential of Bach's fugues and the super dominant seventh characteristic of our very latest composers.

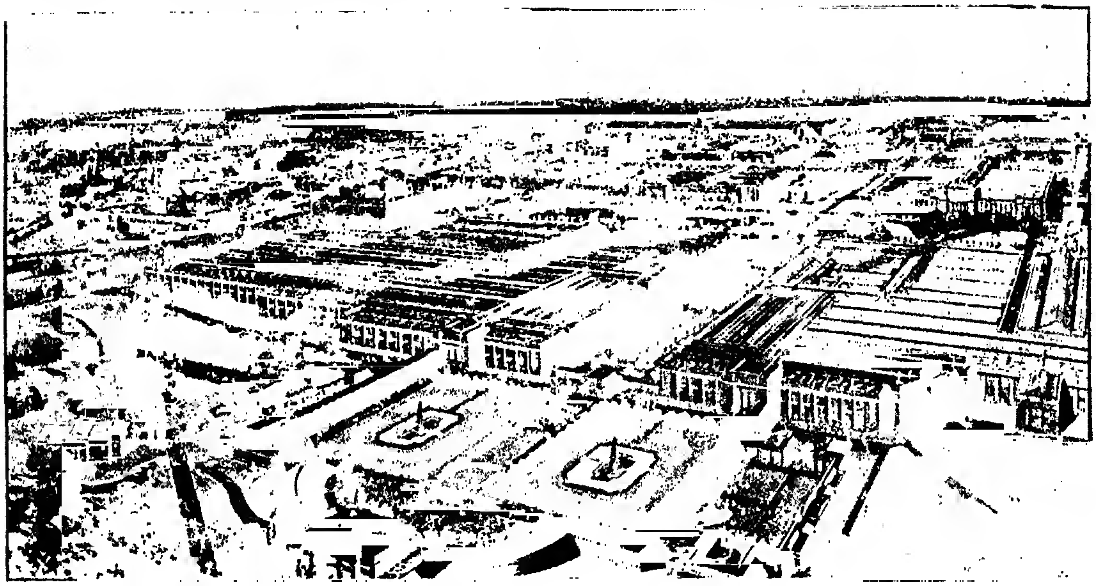
It may be assumed that everyone of sound mind has some interest in science, industry, art, music, sport, history and geography. Here is something for everyone and we think that the huge Engineering Palace and the huge Palace of Industry, in which latter are the chemical exhibits, will provide interesting matter for many of the visitors. Chemists should make a point of seeing this exhibition as

frequently as possible; they will be reminded of many half-forgotten facts of chemical history, they will be vividly impressed—if they are not already of a sufficiently guid conceit—by the way in which chemistry is being utilised in industries which formerly dispensed with it.

So vast an Exhibition demands a good deal of time; it is better to go for two or three hours than not to go at all, but probably those who go a dozen or a score of times will find they have still many new things to distract them. You are surprised by some building, half hidden, or unnoticed and you find it is a singularly interesting symbol of Aden or Fiji or East Africa or Jamaica or the Falkland Islands until finally you are profoundly impressed by the extent and the variety of your Empire. Mere maps, Whitaker's almanacks, statistical reports and the works of Flavius Josephus that learned Jew—will never drive this home. Of course we all know about the Malay Straits—or is it States?—and of false sizes and in false bearings, is more dangerous than utter darkness. The Wembley Exhibition gives us a reliable standard. If it includes Malta and Ireland these still form part of the Empire. We hunted all over for Minorca, Boothia Felix, and the Ionian Islands which we were doubtful about and found none of them. If the next time we are equally unsuccessful we shall conclude that Napoleon or Washington deprived us of these. A collection of postage stamps is not an infallible guide but the Empire Exhibition is. By the way, why was Boothia called Felix? Felix calls up some recollection, we know not what, some phrase we have recently come across.

The Palace of Industry: The Chemical Section

Keeping on walking and turning to the right we now enter the Palace of Industry which includes the Chemical Section organised by the Association of British Chemical Manufacturers. A large committee



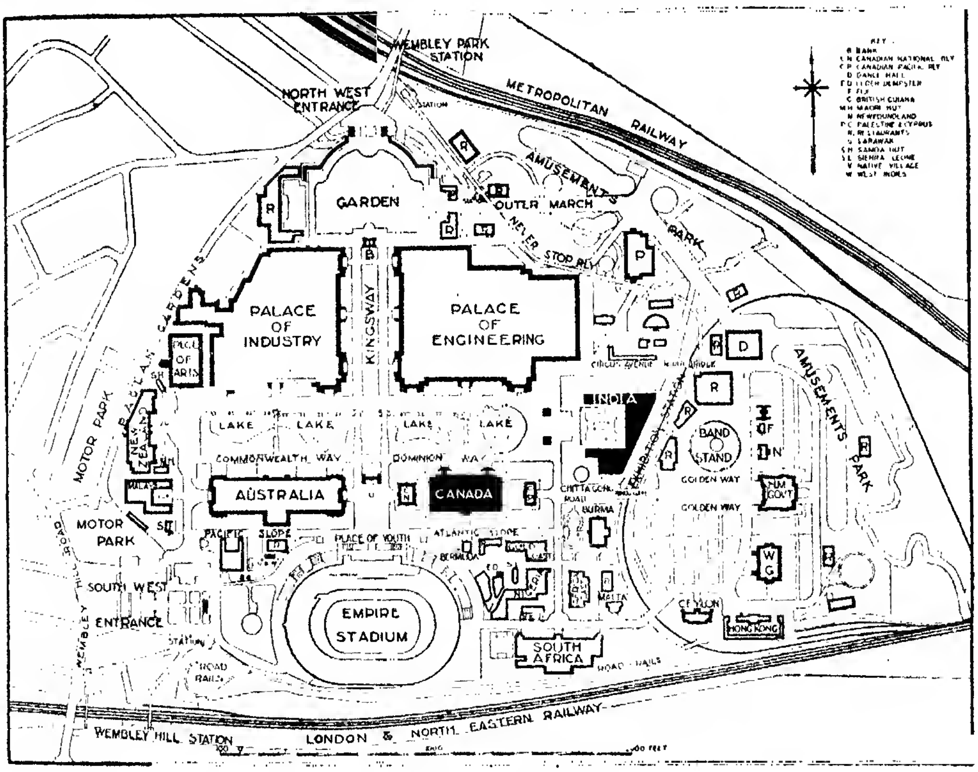
Stamford Raffles, but it is such a long way off, and a long time ago, and perhaps it isn't true. And then we find a building with a dome and minarets of truly Oriental flavour, filled with products from the spicy islands, and we seem to be in touch with something real at last. We would be prepared to testify about it in a court of law or even to wager a brother chemist the price of a dr***. It has always been a mystery to us how people can imagine they believe half the things they think they do believe. The legendary imperceptibly pass into the historical; Armstrong's views on ions and ikons are Findlay's views, but seen through a different medium. Armstrong no doubt thinks of the ionic medium, as Macaulay put it, just as that transparent haze, through which the sailor sees capes and mountains was concerned in the organisation of this Section. It consisted of Mr. W. J. U. Woolcock, the Chairman, Sir Max Muspratt, Bart., and Mr. R. G. Perry for the Association of British Chemical Manufacturers, Mr. Chester Fox for the United Kingdom Soap Makers' Association, Dr. E. F. Armstrong, Mr. E. V. Evans and Mr. J. L. Baker for the Society of Chemical Industry, Mr. R. Gosnell and Mr. H. Barrett for the Perfumery Committee, Mr. E. Hickson and Mr. J. B. Atkinson for the Society of Dyers and Colourists, Mr. C. A. Hill and Mr. Wippell Gadd for the Drug Club, Mr. E. O. Hughes and Mr. P. G. Somerville for the National Benzol Co., Ltd., Mr. F. Kingzett and Mr. Godber for the British Disinfectant Manufacturers' Association, Commander R. E. Stokes-Rees for the Institution of Petroleum Technologists,

Dr. J. T. Hewitt and Professor J. F. Thorpe for the Chemical Society, Mr. R. Pilcher for the Institute of Chemistry, Dr. S. Miall for the Federal Council, Mr. T. H. J. Carroll and Mr. F. C. O. Speyer for the British Sulphate of Ammonia Federation, Mr. L. M. G. Fraser for the British Chemical Plant Manufacturers' Association, Mr. N. Garrod Thomas for the National Sulphuric Acid Association, Mr. E. T. Nethercoat and Mr. T. Marns for the Pharmaceutical Society, Mr. S. Sadler for the Association of Tar Distillers, and Professor Hinchley for the Institution of Chemical Engineers.

This Committee held several meetings in 1922, 1923 and 1924 and the advice of its members was doubtless of great value to the Exhibition authorities,

The Scientific Exhibit

One of the most original features of the Chemical Section is the scientific exhibit intended to illustrate the work of the present generation of British chemists. This has been organised by a sub-committee of the large A.B.C.M. committee previously mentioned. The sub-committee which had as its chairman Dr. Herbert Levinstein, was assisted by many of the most noteworthy of our chemists and kept closely in touch with the committee of the Royal Society so as to avoid unnecessary overlapping. Dr. Levinstein devoted himself to this agreeable task and secured help from all those universities and other places where chemical research is carried on. He has taken immense interest in this exhibit and the



Plan of Exhibition

but the driving force was that of the chairman, Mr. Woolcock, and he did the lion's share of the work; and a very considerable and notable piece of work it was. Mr. Woolcock was suave, tactful or threatening as occasion required; he has a *curiosa felicitas* of his own, a disingenuous and courteous bluntness which is difficult to resist. By judicious cajolery, flattery, determination and attention to detail he got the business through and the chemical section was always as far ahead as any other. Everyone who visits the Chemical Section should feel a little grateful to him.

result fully justifies the time spent on it by him and his co-workers.

In the centre of the Scientific Exhibit is the Fiery Fountain, an attractive scientific toy which will probably interest the general public more than the other exhibits of more scientific importance displayed in this section.

Issuing from a rock is a stream of water flowing in a graceful curve on to a glass flower and thence overflowing into a mossy pool. As the stream of water touches the flower it appears to catch fire and the flower is brightly illuminated by fiery water.

As you look, the colour changes from fiery white to fiery red, from fiery red to the vivid green like that shown by a Verey light, but the water flows over the flower entirely colourless. As it falls on to the tank below it again shows a brilliant iridescence.

Many pretty experiments have been shown with phosphorescent and fluorescent substances. Most of these depend for their full effect on a darkened room. Here we have daylight and no doubt many besides the general public will be puzzled to know how this pretty and attractive effect is obtained.

The exhibit has been prepared by the Manchester College of Technology. Many experiments have been made to bring this device to perfection and Principal Mouat Jones and Mr. Hodgson are to be congratulated on providing a very successful and ingenious attraction.

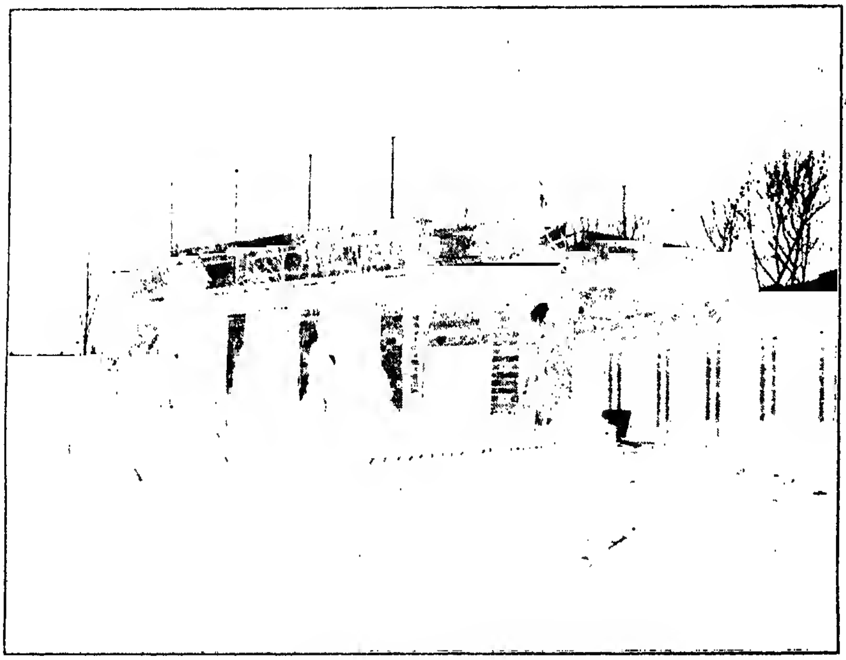
The Alkaloid Section, organised by Dr. T. A. Henry and Professor F. L. Pyman, consists of a large number of little bottles containing crystals and powders of all kinds and colours and interspersed among the bottles are cards with chemical hieroglyphics inscribed on them.

The diagrams with their mysterious hieroglyphics shown in these cases tell the story of how much has been achieved for each alkaloid dealt with. Thus, one of them shows how it is possible to start with a component of nutmeg oil and passing from it through a whole series of compounds to arrive at alkaloids such as cotarnine and hydrastinine, which have important medical applications as styptics and from these in turn even more complicated alkaloids have been produced.

Apart from these medical and chemical aspects of alkaloids, they are not without interest in other directions. Thus the exhibit includes a comprehensive series of the highly poisonous alkaloids obtained from the aconites of Japan, India and England. Aconite roots have been used as arrow poisons as well as in medicine, and they owe their use in these directions to the toxic alkaloids they contain.

Finally it may be of interest to add that the specimens shown represent work done wholly in Great Britain, that practically every type of alkaloid is included—a sure sign of the importance of the British contribution to knowledge on this subject—that every important British authority on alkaloids has contributed to the exhibit, and that no such collection has ever been got together before.

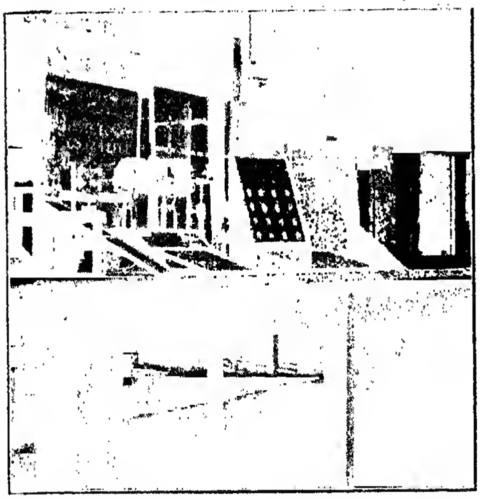
The exhibit of Inorganic and Physical Chemistry was arranged by Prof. F. G. Donnan and is very comprehensive. It includes apparatus for determining the rate of solution of gases by water, lent by Prof. Adeney. Prof. Allmand shows photochemical cells, electrolytic manganese and other objects of interest; Prof. Bassett shows models and specimens to illustrate the phase rule. Dr. Egerton shows specimens of distilled metals and notes of various vapour pressures. Dr. Friend has an exhibit showing the corrosion of metals and the various pigments which are used to prevent corrosion. The Royal Institution shows some of the Historical



The Main Entrance to the Grounds

Collection of Apparatus of the late Prof. Sir James Dewar, and there are several other exhibits of apparatus used by physical chemists.

Prof. McBain has done much original work on colloids and the committee gladly availed itself of his help in organising the exhibit of colloid chemistry. Dr. Hele Shaw's Stream Line Filter shows how colloids may be filtered. Banded precipitates are shown by Dr. Bradford and Mr. Emil Hatschek. Many chemists who know these only



In the Scientific Exhibit

from illustrations in books will be glad to see actual specimens. Prof. McBain himself has an exhibit of soap solutions and other exhibitors show colloidal rubber, clay and carbon. Prof. Hardy's work on the distribution of water in a gel is also shown.

There are exhibits showing the progress in explosives during the years 1900–1924 collected by Sir Robert Robertson and lent by the Board of Trade, the Imperial War Museum, the Science Museum, the Research Department of Woolwich, Messrs. Nobel's Explosives and others. Some of the exhibits refer to an earlier period, for instance, the first practical smokeless powder made so long ago as 1882 by Mr. Walter F. Reid, a former President of the Society of Chemical Industry. There are models of plant for the manufacture of guncotton and nitroglycerine and for the recovery of acetone on the lines worked out by Nathan, Thomson, Rintoul and Sir Robert Robertson himself. There are devices for detecting the gradual decomposition of nitroglycerine, the calorimetric apparatus of McNab and Leighton for determining heat values of gases and sundry information about the new explosives developed during the war and models of plant for their manufacture.

Crystal structure as we now understand it, owes much to the labours of the Braggs. Prof. W. L. Bragg shows a considerable number of models of crystals made to a scale of one hundred million to one.

There are exhibits arranged by Prof. Smithells to show the structure of coal, the nature of flame and the removal of sulphur compounds from coal gas.

The Cavendish Laboratory of Cambridge shows a number of interesting things, diagrams explaining much of the work of Rutherford, Geiger, Andrade and Moseley: photographs of mass spectra by Aston, and of α-particles by Wilson. The importance of this work and the valuable contribution to knowledge made by the Cambridge school, are well-known to most of our readers. This exhibit has been organised by Sir Ernest Rutherford.

Dr. Ormandy has arranged a number of exhibits of various plastic materials, the conversion of cellulose into sugar: phenol and cresol condensates prepared by Synthite, Ltd. and the Damard Lacquer Co., also casein products prepared by the Erinoid Company.

The metallurgical exhibit is not a large one, having regard to the great mass of recent work on the structure of metals, but it is not easy to show in such an exhibition the microscopic structure of steels and alloys. The microscope is becoming of considerable importance in many industries, and the industrial section of the Royal Microscopical Society will convince anyone who is fortunate enough to attend its meetings how many problems the microscope is helping to solve. Prof. F. C. Thompson has taken charge of this exhibit, which includes some interesting exhibits of the crystallisation of metals.

Colouring matters always form an attractive display; the scientific work done here in this branch

In the Scientific Exhibit

of chemistry is not so easy for him who runs to read as is a mass of brightly-dyed fabrics. Prof. Hewitt has, however, collected some interesting things, some original dyes prepared by Sir William Perkin, sixty or seventy years ago, natural dyestuffs prepared by Prof. A. G. Perkin, the plant pigments, anthocyanidins extracted by Dr. Everest and the pyrylium salts made by Prof. Hewitt. There are also dyestuffs shown by Prof. Heilbron, Dr. Silberrad, the British Dyestuffs Corporation, and L. B. Holliday and Co.

The English and Scotch chemists have carried out some important investigations on the structure of terpenes. Hard thinking and logical reasoning on these subjects do not necessarily impress the imaginations of some thousands of visitors who have never heard of a benzene ring. The terpene specimens provided by Prof. W. H. Perkin and Prof. G. G. Henderson will nevertheless be of interest to all who have studied organic chemistry.

Catalysis is of great importance industrially, and the theory of it is both difficult and interesting. Dr. Hilditch has gathered together some good models and units of plant employed by the United Alkali Company, and some oils hardened by catalytic processes, prepared by Messrs. Crosfields, Ltd. The words catalysis and analysis have always appealed to chemists; in Greek it would seem that they mean, respectively, breaking down and breaking up, though catalysis is the exact equivalent of the phrase, breaking up, as applied to a school. The idea of catalysis is very closely akin to the idea of rest after labour, a sojourn in a country inn at Lyme Regis, after a busy term at Sheffield. This is catalysis as the old Greeks would have understood it. Some favoured visitors may have the opportunity at the Exhibition of seeing catalysis as applied to editors.

We have not forgotten the exhibit of chemical engineering arranged by Prof. Hinchley, but as we intend to have a special article dealing with chemical engineering at the Exhibition, a fortnight or three weeks hence we will not deal with this now, except to mention that it is worthy of a visit.

This scientific exhibit and the book written as a supplement to it to record the recent advances in chemical knowledge in this country, bring home to us the flourishing state of chemistry. So far as the Structure of the Atom is concerned we may well be proud of the British share. This particular subject will fill us with pride until some daring speculator shall advance new and better hypotheses.

Man does with dangerous curiosity,
These unfathom'd wonders try:
With fancied rules and arbitrary laws,
Matter and motion he restrains:
And studied lines and fictions circles draws:
Then with imagined sovereignty,
Lord of his new hypothesis he reigns.
He reigns: how long? till some usurper rise;
And he, too, mighty thoughtful, mighty wise,
Studies new lines, and other circles feigns.

These verses are almost as true to-day as they were when they were written, nearly two hundred and forty years ago.

This Exhibition has taken two years to organise, and has cost twenty million pounds sterling to build. It always seems more impressive to put in the word sterling; its significance is nevertheless comparable to the mere expletive. And at the finish there is a rush and a scramble to get things done in time, late and early hours spent in hurried work. The book we have spoken of, a record of modern British chemistry, prepared by the greatest living experts in their own departments, is an instance of this. Dr. E. F. Armstrong, who has edited this and written an excellent introduction to it, has had to issue frantic appeals at the eleventh hour to authors, printers, publishers *et hoc genus omne* to get the compilation ready in time. He has done it and done it well, but probably he has had to sit up so late that hardly here and there a hackney coach, appearing, showed the ruddy morn's approach.

Even the editorial staff wish that Special Numbers did not coincide so nearly with Easter holidays, making an undue rush to print two numbers in one week, and they regret the light-hearted way in which, four or five months ago, they undertook the issue of a set of elementary pamphlets, intended to show how chemistry pervades the whole of human life, beginning with the laws which keep the planets in their radiant courses, and ending with some precept deep for dressing eels or shoeing horses, ranging in fact from stellar chemistry and biochemistry to metallurgy. But the one man whose task we have not coveted and whose responsibility we have not envied is Mr. Woolcock.

The Chemical Exhibit

Heavy Chemicals

No exhibition, including the chemical industry, would ever be complete without the participation of those two giants in the chemical trade, Brunner, Mond and Co., and the United Alkali Co. So much could be said about either of them that it is difficult to know where to begin. Brunner, Mond and Co. not only exhibit a full range of their own products at their stand, but provide space for their subsidiary companies. A special feature is the demonstration of P. 84 silicate of soda for hardening concrete, and samples of other grades of silicate of soda suitable for other purposes are also to be seen. All sorts of products ranging from soda ash to caustic soda, ammonium chloride to calcium chloride are there, to remind the onlooker of the importance of the alkali industry whether to other industries or to the home. Attention should be called to the exhibit of crystal calcium chloride, which contains up to 75 per cent. of the salt and is of pharmacopœal purity in regard to its content of arsenic.

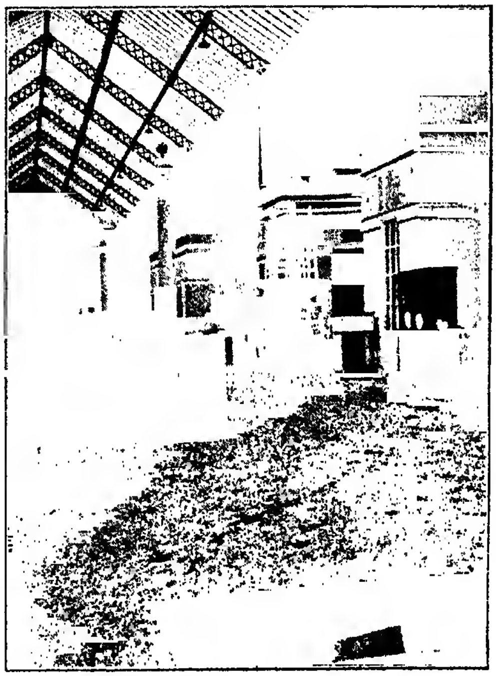
Of the subsidiary companies, the Castner-Kellner Alkali Co., Ltd., provides exhibits which show the extraordinary range of uses to which its products are applied and remind one that its works, engaged in the manufacture of sodium and chlorine products, ranging from metallic sodium to hydrochloric acid, are remarkable for their scientific planning and equipment. Those interested in the soap, dyestuff, paint, oil extraction, rubber or laundry industries, will find a visit to this stand well worth while. An electrolytic process of a different type is also utilised by Electro-Bleach and By-Products, Ltd., to manufacture chlorine, soda, bleaching powder, sesquicarbonate of soda and salt. An interesting by-product of the manufacture of caustic soda by treating sodium carbonate solution with lime is carbonate of lime, which, produced in a very fine state of division, is eminently suitable for agricultural use and for "stone-dusting" mines. Many high-grade chemicals are shown by Chance and Hunt, Ltd., a firm which supplies ammonium carbonate

(for the baking trades), caustic soda, sulphuric and hydrochloric acids, ammonia, sodium sulphide of various grades, saltcake for glass and paper making and iron-oxide pigments. This firm neglects no opportunity to improve its products or processes and is willing to investigate problems connected with the use of its products. The Calder-Fox scrubber patented by the company is a successful method for removing acid mist in the exit gases from sulphuric acid concentration plants, and information about it is willingly given to intending users. Lime in one form or another fills a multitude of users, amply illustrated by the Buxton Lime Firms Co., whose output exceeds a million tons a year. The physical and chemical properties of lime are too often neglected, but the products of the company possess characteristics that comply with needs ranging from agriculture to concrete making, water softening and various chemical processes. Synthetic Ammonia and Nitrates, Ltd., whose works for the fixation of atmospheric nitrogen at Stockton-on-Tees are now completed, exhibits samples of ammonia and sulphate of ammonia that remind one that, although the plant can produce nitrogenous fertilisers in quantity, it could, in time of war, supply huge quantities of nitrates, thus rendering the country independent of foreign supplies.

No introduction is needed by the United Alkali Co., which, though a descendant of the pioneers of the British chemical industry, is as new in its processes as it is old in years. Although samples of the company's products are shown in various portions of the stand, the main object of the exhibit is to show, by photographs and other means, how widely those products are utilised in the various industries of the country, whether the manufactures be paper, glass, textiles, dyeing, printed calico, galvanised iron, foodstuffs, leather, or even ice. Thus the bleacher and the mineral-water maker, the match maker, and wire maker, the cotton printer and the water engineer are all beholden in some way to the United Alkali Co. The chief manufactures at the company's various works are, of course, sulphuric acid, caustic soda, soda ash, and chloride of lime, all products essential to industry, but it should also be pointed out that the company is the largest manufacturer in Great Britain of that most important fertiliser, superphosphate, and that others of its products such as salt, soda crystals, and cleansing materials are as indispensable in the home as superphosphate is on the farm. An interesting development of the company's scope is the manufacture of organic chemicals and dyestuff intermediates, of which the national importance is shown in a diagram that should be seen by all those who are interested in the continued growth of the dyestuffs industry in this country.

Another of the firms which extract salt from the mid-Cheshire brine fields is Murgatroyd's Salt Works, Ltd., and their stand is remarkable for the number of grades of salt shown. All grades are there, from coarse salt for curing fish, dairying, cooking and the table, up to fine salt that is analytically pure, and including even salt that will not cake when exposed to damp, the change being produced, not by adding substantial amounts of other chemicals, but by physical treatment. In addition, a coarse, uniform salt is shown that does not "ball"; it is supplied for the manufacture of salt cake and a quality is made free from calcium and magnesium compounds. Here on this stand can thus be seen one chemical which, in various grades, covers the range from fine to heavy chemicals, as well as being an important food adjunct, a supply of 15 lb. per annum being necessary for health for a grown man.

In their exhibit, Messrs. F. W. Berk and Co. chiefly show specimens of their main products, hydrochloric, nitric and sulphuric acids for a variety of uses, as well as samples of other of their well-known products, including lactic acid, hydrogen peroxide, alkaloids, mercurials, sulphur, mercury, potash salts and a large range of crude drugs. This



Part of the Chemical Hall as it was

company specialises in the export trade, being a merchant as well as a manufacturer, and the exhibit also shows the methods of packing materials for export so as to ensure both safety and economy. The company owns works both at Stratford, London, and at Pentrepoth, Swansea, and as the heads of the various departments have been with the firm for periods ranging over forty years, an accumulated experience and a knowledge of requirements are available that are not less valuable to the buyer than the technical qualifications at command.

A useful range of industrial chemicals is exhibited by J. M. Collett and Co., Ltd., of Gloucester, their exhibit including the metabisulphites of potassium and sodium, the sulphites of lime and soda, as well

as sodium bisulphite (anhydrous and liquid) and bisulphite of lime.

On approaching the stand of Joseph Crosfield and Sons, Ltd., one is immediately reminded of soap, of course, but there are other products of this company that are equally noteworthy. Take Crosfield's Pyramid brand glycerine, for instance. This is supplied in qualities suitable for use in the manufacture of many chemicals and industrial products, such as lubricants, leather dressing and polishes, inks, toilet preparations, drugs, and then it finds use in surgery, printing and dyeing. Caustic soda is an important product of this Warrington firm, but there is also silicate of soda—and it is time that the public realised that this protean body has many other uses than that of preserving eggs; it is a universal adhesive as well as a "hardener" for concrete and cunningly changed in form, it becomes Doucil, the new material for softening water and absorbing vapours. Visitors to this stand will not fail to be impressed with the complexity of modern industry, as illustrated by a firm whose products range from soap to cement, and if they realise the quality of the scientific direction that lies behind it, all the better for chemists and chemistry.

The fine colour of the exhibit of sulphate of copper by James H. Dennis and Co., Ltd., cannot fail to catch the eye. The product, of which the firm is the oldest and largest maker in the world, is of 98 to 99 per cent. purity, and has been used to protect the French vines from diseases for over fifty years. It is used for the prevention of plant diseases, as a weed killer, for purifying water, and as an addition to asphalt to make improved road material. Those who have seen the ravages of disease in the vine yards in certain years will understand the importance of this cœrulean chemical.

A large number of industries will find attractions at the stand of B. Laporte, Ltd. There is hydrogen peroxide of all strengths and qualities for bleaching wool, silk, straw plait, gelatin and many other products, and barium salts are present in quantity, such as barium peroxide (which is not only the purest made, but also the only British make), the carbonate for the ceramic, glass and sugar industries, the sulphide for the tanner and the purification of acid, and the sulphate, known in the colour trade as blanc fixe. Sodium salts are there, too, whether the hypochlorite or pyrophosphate, the acid pyrophosphate used in baking, the sulphide, bisulphite, perborate—all of such great industrial utility. Soap, washing powders, blues and other laundry requisites, are also shown, in addition to sundry preparations for various technical and trade purposes.

Nickel and its salts and the Maple brand of copper sulphate predominate, as might be expected, at the stand of the Mond Nickel Co., and will remind the scientific observer of the beauty of the process by which nickel is purified, the impure material becoming the attractive metal that is now so ubiquitous, whether as coinage (and the company has supplied several foreign Governments for this purpose), or as a shining mask for baser metals in a thousand different ways. Next time visitors are "abroad," the sight of the clean, bright coinage in Belgium and other countries will bring up memories of the stand of the Mond Nickel Co. Some of the metals of the platinum group are also produced by this company, so its stand does not lack interest.

Sulphuric acid is so important a chemical, such an index to the general industrial prosperity, that it may be said to carry its own recommendation, and Spencer Chapman and Messel, Ltd., have made it so long and so extensively, that little remark is needed. In an oval glass case stands a central bottle filled with crystals of sulphur trioxide, and surrounding it are specimens of oleum and sulphuric acid. Charts are exhibited showing the various properties of these two products, and the stand should not fail to impress those who can appreciate the vast economic import of the crystals and specimens displayed with such elegant simplicity.

To the uninitiated it may come as a surprise to hear at the stand of the Washington Chemical Co. (with Turner Bros. Asbestos Co., Ltd.) that the works of this company, covering 50 acres, and the largest of its kind in Europe, produces solely magnesia in its various forms. But there it is: magnesia, light, heavy or calcined, is used in making rubber products such as tyres, in making explosives, soap, ink, enamelware, scientific glassware, china, paper and toilet papers, and it is to be found even in fine table salt. Founded in 1840 by Pattinson and Newall, both Fellows of the Royal Society, the company has developed continuously, and whether "Pattinson's" magnesia is used in the pharmacy or in industry, the product is always found to be uniform in colour, texture, composition, and purity.

No-one should miss the wonderful display of crystals of various alums on the stand of Peter Spence and Sons, Ltd., a firm with nearly 80 years' experience behind it. One huge crystal weighing over 200 lb. took four years to grow, and is probably the largest single artificial crystal ever produced. On each side of this exhibit is a large pyramidal column, over 5 ft. high, which is built up of about 140 practically perfect octahedral alum crystals. But there are many other exhibits besides crystals, such as the specimens illustrating various salts of aluminium, and their manifold applications in dyeing, paper making, leather manufacture, fire-proofing, water purification, and the specimens of titanium preparations, *e.g.*, titanous chloride and sulphate used for reducing and stripping, and titanium potassium oxalate, used in dyeing leather. Messrs. Spence also show sulphuric acid, carbonate of lime, silica and various other industrial materials of which they are large producers.

"How was it done?" This question was asked by a visitor on hearing that Messrs. J. and E. Sturge, Ltd., manufactured the required grade of precipitated chalk, not by mixing a lighter with a heavier grade, but by manufacturing direct to the bulk required thus ensuring a uniform product that could be repeated at any time. However it was done, Messrs. Sturge's stand exhibits the results, a remarkable range of graded samples, whose structure is depicted in photomicrographs. Pleasant memories are awakened by the exhibit of products derived from the grape, including the more important tartrates.

There are also products derived from the lemon—citric acid and various salts—in addition to potassium carbonate and bicarbonate, and magnesia. All these materials are subject to rigorous analytical control, and are as free from common impurities, such as lead or arsenic, etc., as is possible. So visitors can sip their lemonade or clean their teeth without the slightest fear of ill-consequences.

A beautiful display, both in form or colour, is given on the stand of J. and J. White, Ltd., the oldest and largest manufacturers of chromium compounds in the world, and a striking feature is the contrast between the dullness of the raw materials and the brilliance of the finished products. The chief products shown are potassium bichromate and sodium bichromate, used chiefly in dyeing and tanning, and tanners will be interested in the removal of the uncertainties due to indefinite strength of chrome tanning liquors by the provision of chrome-tan, of definite strength, sold both as liquor and crystals. Oxide of chromium is shown of great purity, for the manufacture of ferrochrome and non-rusting cutlery, as well as for paint making. There are also chromic acid for use in electric batteries, ammonium bichromate, used in fireworks and photography, and a number of other chrome compounds, which, if not of great commercial value, are of note for their variety of colour. An interesting by-product is dry, neutral sulphate of ammonia, a contrast among so much brilliance.

The stand of Baird and Tatlock (London), Ltd., brings up memories recalling the astounding feats of genii in the Arabian Nights. Was something wanted hurriedly in the laboratory, Baird and Tatlock used to produce it and even now, despite the scepticism engendered by advancing years, one wonders how they did it. No matter what sort of apparatus was wanted, whether a laboratory bench, a Sohxlet, distillation apparatus, a pipette, or a clay triangle, they had it and all sorts of interesting chemicals as well. They earned a debt of gratitude during the war, and it is pleasant to be reminded of it at their stand.

On the right hand side of the stand of W. J. Fraser and Co., Ltd., Dagenham, is a vertical autoclave with mixer, such as is used for producing organic chemicals, and by it is a horizontal steam-jacketed high-pressure dryer fitted with an internal agitator. These and the other exhibits can illustrate but a small part of Messrs. Fraser's production, which includes chemical apparatus of all descriptions, so recourse is had to photographs showing stills, condensers, autoclaves, mixers, heaters, coolers, driers, pans, tanks, conveyors, pumps, and compressors, and even weighing and measuring apparatus. There is also a large model of a Mills-Packard sulphuric acid plant, and the stand should be visited by those who wish to know what a chemical plant manufacturer in this country is doing.

Coal and its Products

At the sign of the Benzene Ring used so cleverly for decorative purposes by the South Metropolitan Gas Co., the tyro will learn more about Metro chemical products derived by distilling coal. Metro sulphate of ammonia, presented in glistening bulk in terrace-garden-like surroundings, shows that its reputation for dryness and neutrality is deserved and the wooden balustrade around it is stained in various shades to show the series of browns obtained by treatment with Metro creosote. Noticeable are the gas-lighting arrangements displayed above samples of solid smokeless fuels held in braziers surmounting four octagonal cabinets, each of which contains Metro products such as dye intermediates, ammonia, coal tar of various grades, pitch and heavy inorganic acid. Other specialities to be seen are road tar to the specification of the Ministry of Transport, a powerful disinfectant fluid, benzol, and pitch. It is a long step from Durham coals to Metro dye

Another Portion of the Chemical Hall

intermediates, but there they can be seen, and though samples of gas will hardly be shown, its qualities are well enough known to the seething populations of South London.

The Gas Light and Coke Co. bears its 111 years of existence lightly, and provides a stand showing not only its well-known products such as tar, ammonia and cyganogen compounds, but also some of its later developments such as betanaphthol and naphthalene, cresol and pale liquid carbolic acid of much higher purity. The company and its products are too familiar to need any introduction and it will suffice to point out that on the stand there is a working model to demonstrate the ease with which the company's neutral sulphate of ammonia can be applied to the soil, a point the importance of which can be fully realised only by those who have had to cope with rotted bags and a clogged fertiliser drill during a short spell of fine weather at sowing time.

The Uses of Tar

The public is beginning to realise that tar has uses other than on roads or sheds. The examples of primary and intermediate products obtained by the distillation of coal tar exhibited by the Midland Tar-Distillers in co-operation with the South Western Tar-Distilleries and Messrs. Burt, Boulton and Haywood Ltd., should give more valuable enlightenment. Samples of products for treating roads, for horticulture, disinfecting, tanning and for medicinal use are on show, and there are interesting models of the Midland Tar Distillers' plant for the continuous distillation of coal tar and of the Burt, Boulton and Haywood creosoting plant. One is glad to see the range of useful and ornamental articles manufactured from phenol by Synthite, Ltd., which is the largest manufacturer of formaldehyde in this country. The process used is, of course, that in which phenol is condensed with formaldehyde to produce plastic materials, which are coloured, shaped and treated so as to produce various articles.

Messrs. Burt, Boulton and Haywood are also exhibiting at another stand, where samples of wood preservatives are accompanied by specimens of timber creosoted over 70 years ago, showing the efficiency of creosote for preserving wood. All types of disinfectants are exhibited, and an interesting new product is colloidal sulphur, which is finding increased use in horticulture and veterinary work. On the same stand, demonstration is given of the Premier Mill, together with finely ground pigments, emulsions, and other products prepared by it.

Jeyes Sanitary Compounds Co., do not desire so much to delight the eye as to impress the mind, as their stand is designed to show the great stability, high germicidal strength and relative non-toxicity of Jeyes Fluid and Cyllin. The apparatus for standardising disinfectants by means of the Rideal-Walker test is demonstrated at the stand, and in addition to several sanitary preparations, an alarming series of bacterial cultures from town air and other sources of infection attracts attention.

An illuminated globe representing the world is found at each corner of the highly original stand of Newton Chambers and Co., Ltd., and Izal Germicide appears to be overflowing from the huge bottle in the centre, supported on a pylon, and running in streams to every corner of the globe. The bottle rests on a glass stand showing silhouettes of the company's collieries and chemical and iron works and the supporting pillar springs from those key-products, coal and iron. Show cases contain an array of other products manufactured by the company, which dates back to 1793.

The Kalbitum Paint Co. show black bituminous paint that is claimed to be an efficient and economical preservative for iron and steel work in many kinds of plant. The paint is applied cold and does not require skilled labour. An attractive blend of colours characterises the stand of the Keystone Varnish Co., which exhibits paints, varnishes and enamels for a wide variety of purposes.

Dyestuffs and Intermediates

A lighthouse, happily surmounted with a block of coal and surrounded by resplendent columns, summons with its flashing lights the curious to a stand that is a fairyland—or is it an Aladdin's cave?—of light and colour. The British Dyestuffs Corporation, Ltd., secure in the glow of colour from cotton and silk, velvet and muslin dyed with its products, has largely dispensed on its main stand with the usual show of samples in bottles, and the result is singularly attractive. Their flashing lighthouse dominates the hall, but without its call there is interest enough. Imagine a large exhibit which demonstrates the various stages of the dyestuffs industry from prehistoric days up to those of Perkin and the present time! There are colours out of date, colours up to date and colours that have apparently just emerged from the factory. The public will begin to understand the real significance of that trite expression, a feast of colour, and incidentally will gain a pleasant—if distant—glow of proprietorship in considering the improved fortunes of this national company. But what a task was that of selecting material for this stand! To choose exhibits from materials that are used in dyeing every kind of textile, in making lakes for paint, varnish, distemper, ink, in dyeing leather, in curing disease, in vulcanising rubber, in colouring photographic films is obviously not easy—there surely must be a B.D.C. colour for every known purpose and some new ones. And if you want your bottles, there on another stand are specimens of fine chemicals, photographic chemicals, medicinal chemicals and many more. And if you want to know anything, a chemist will tell you how the dyes are made and another gentleman will sell you any quantity, swiftly, painlessly, and economically.

The exhibit of the British Alizarine Co. will certainly attract much attention, whether from the point of view of the colour or the quality of the products shown. Here can be seen all sorts of alizarine colours, reds, oranges, pinks, mauves, blues, greens produced on different materials by the various methods set out in the company's pattern cards. A noticeable feature is the large number of shades such as salmons, terra-cottas and other mixed shades obtainable in printing on cotton with Alizarine Orange. Then there are the Anthracene Browns, and a fine series of Alizanthrene Vat Dyes on cotton yarn. There is much attractive material on this stand.

A visit to the Colne Valley in Yorkshire leads to the acquisition of much knowledge. The wise man will in some parts learn how not to be a "furriner" and how to pronounce Slaithwaite as Slowitt, and if he goes to Milnsbridge he will find, in a valley where factories hum amidst stark uprearing rocks the Colne Vale Dye and Chemical Co., Ltd., who, in that greyness, produce aniline dyes to clothe the native in Kamchatka or Benin or to ornament the coster's Sally on Hampstead Heath or someone's Harriet on the Great Orme. Their telegraphic address is Aniline, Huddersfield, and their stand is easily found at Wembley.

The interesting exhibit of the Clayton Aniline Co., Ltd., illustrates the complete range of products manufactured by this firm, samples of about 250 colours and 100 intermediates being shown, in addition to samples demonstrating the working up of raw materials into dyestuffs and the application of dyestuffs in dyeing, painting, printing, leather treatment and other trades.

The policy of Hickson and Partners, Ltd., to make only a few colours but to make these on a large scale will attract visitors to their stand, especially as the firm claims to be the largest maker of Roseine in this country. This dye is, of course, magenta, but as the firm believes in British names for British products, the original name of Roseine, due to Brook, Simpson and Spiller, has been given to it. The stages in which the firm's products are manufactured are shown in an attractive manner, the care taken to keep a high standard of purity being very noticeable, and giving an explanation of the excellence of the effects produced by this firm's dyes, which are finding important outlets at home as well as abroad.

A most original and instructive stand is that of L. B. Holliday and Co., Ltd. Realising the bewilderment that must result to visitors confronted with a large number of dyes accompanied by samples to show the great variety of their applications, the firm has provided a demonstration to prove that British-made dyestuffs are equally fast as the best foreign dyestuffs. The samples exhibited show that the comparison is in no way to the disadvantage of the British product. This exhibit should dispel any lingering notions that British-made dyes are of other than first-class quality.

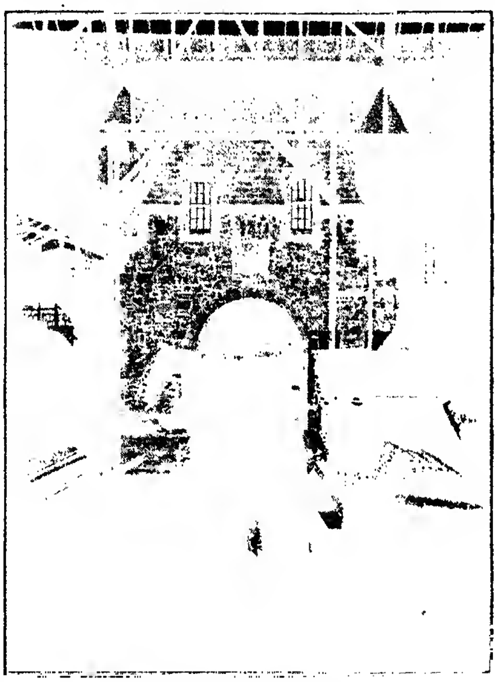
Mention "Nigrosine" or "Induline" and one thinks at once of Williams Bros. and Co., a firm which is the oldest and largest maker of these colours in the country, as well as a large producer of aniline dyes for use in the manufacture of leather, polishes, inks, stains, varnish, soap, candles and many other products. Selections of the firm's manufactures make an attractive display, and those who are dismayed on seeing the appetising custards, egg powders and other foods tinted with the firm's colours can easily be reassured, as all the products supplied for tinting confectionery have long been shown to be harmless.

A fine show of colour greets the eye at the stand of Scottish Dyes, Ltd., a company which specialises in anthraquinone dyes for cotton and silk and acid alizarine dyes for wool. Specimens of intermediates such as anthranilic acid, anthraquinone, methylamine hydrochloride, naphthanthraquinone and phthalic anhydride are to be seen, but pride of place is given to the standard dyes manufactured by this firm, and the range of textiles dyed with these colours worthily uphold the Scottish claim for excellence.

Dyes are also shown by the Ajax Aniline Dye Manufacturing Co., Ltd., suitable for a wide range of materials, including leather, artificial silk, carpet yarns, and the exhibit comprises bottles of dyes and intermediates as well as a slection of dyed samples. Three glass cases containing various chemicals and direct cotton, acid, chrome, union, leather, jute and paper colours are exhibited by J. C. Bottomley and Emerson, Ltd.

Fine Chemicals

The British Drug Houses, Ltd., known familiarly as the B.D.H., must have had a difficult task in deciding what to exhibit at their stand, as their output and range of chemicals and pharmaceutical products is said to be larger than that of any other similar firm in the world. However, the stand is thoroughly representative and visitors can choose between the



In the Palace of Industry
The Distiller's Stand

attractions of the section for medicinal chemicals, or those for laboratory chemicals, for pharmaceutical products, or for pharmaceutical and toilet specialities. The medicinal chemicals include complex synthetic organic compounds as well as active principles of natural origin, but pride of place must be given to insulin, which was actually placed on the market after only three months' preparation and is now being produced in an improved form at the rate of 200,000 doses a week. It will be remembered what good work the B.D.H. have done during and since the war in providing a British source of laboratory chemicals. More than one chemist has given testimony to the value of their catalogue listing over 3500 analytical reagents and laboratory chemicals of guaranteed purity, there being over 3000 research chemicals alone. There are indicators used in determining hydrogen-ion concentration and stains and dyes for microscope work, and many out-of-the-

way chemicals are stocked because, though they may not be often wanted, when they are, they are wanted quickly. Then there are exhibits of pharmaceutical preparations and of proprietary, pharmaceutical and toilet articles, including a "vanishing cream"—but those who want to know how this is made must go to the stand and ask for the Record of the B.D.H. exhibit.

Boots' Pure Drug Co., Ltd. confine their display almost solely to fine chemicals, including alkaloids, anæsthetics, antipyretics, antiseptics, hypnotics, perfume bases, and research chemicals. A chart and samples are shown illustrating the manufacture from coal tar of saccharine, of which the firm is the largest British maker, and similar demonstrations are provided for acriflavine, aspirin, and atropine. Of much interest are the special displays of insulin made by the firm and of Stabilarsan, an improvement upon the old German salvarsan. Models of the works and photographs of plants at Nottingham suggest the extent of the firms' activities, and special literature is being distributed, of special interest to chemists being the catalogue of research chemicals, over a thousand now being available.

One hardly knows where to start in describing some of the stands. Take Burgoyne, Burbidges and Co., for example. The exhibit is mainly devoted to medicinal and pharmaceutical preparations. But who can choose between the charms of chloramine T and nitriles, or camphor monobromide and cinnamates; or express a preference for something out of the complete range of analytical reagents shown as against the series of stains and reagents for bacteriological work? Where ampoules and pills compete with amyl esters and floral and fruit ottos, who shall award the prize! And there is chloral hydrate (of which the firm is the largest maker in England), accompanied by its method of production, plain for all to read. But visitors must see the stand themselves.

At the two stands of W. J. Bush and Co., Ltd., visitors will be able to obtain an insight into an interesting industry. Since the war this firm has specialised on the production of fine chemicals used in making essences, confectionery, mineral water, perfumery and soap, and products are also made for lacquerers and varnish makers. Such products must be of reliable quality, and the list of products made by Messrs. Bush indicates that it is beginning to be realised that excellence is no more difficult to find at home than abroad. At the perfumery stand, at which the products of two subsidiaries are shown, attention is at once drawn to the series of preparations containing the famous Mitcham lavender, still the finest of its kind, and there are many other handsome productions on view as well.

A charming setting is given to Messrs. Howards and Sons exhibit, which is housed in a stand that suggests an eighteenth-century apothecary's shop, the effect being enhanced by the inclusion of several interesting old pharmacy jars among the chemicals shown. In this way a reminder is given that, although the firm dates back to 1797, it is modern in every way, whether in its methods of manufacture or packing, or in its increasing range of manufactures. The exhibits are taken from the products as manufactured, and are arranged in groups of particular interest being the quinine section, which includes specimens showing the increased production of quinine alkaloids due to improved methods of cultivation. Bismuth salts, iodides, mercurials, citrates, camphor, boric acid, Epsom and Glauber's salts, aspirin and many other products are shown, and special attention should be drawn to the separate group showing the stages of evolution of aspirin tablets from coal and that of the new synthetic solvents, such as isopropyl, alcohol, cyclohexanol, etc. that are being produced as work in the laboratory is transferred to large-scale production in the factory.

Chemical reagents are rightly made the centre of the large display of fine chemicals on the stand of Hopkin and Williams, Ltd., as the firm was a pioneer in the Empire of this branch of the fine chemical industry, witness their book on "Analytical Reagents." A very good display is made of thorium salts used in the manufacture of incandescent gas mantles and many will see for the first time the series of uranium compounds and cerium compounds used in the manufacture of pottery and the like, as well as of glass, the cerium compounds being also of interest to the tanning and dyeing industries.

Some triumphs of chemistry are to be seen at the stand of May and Baker, Ltd., whose exhibit covers products both for medicinal and industrial use, ranging from Seidlitz Powder to Novarsenobillon, an arsenobenzol compound used for the treatment of syphilis. For the treatment of this disease there is also Arseno-argenticum (sodium silver arsenobillon), Luatol (sodium potassium bismuthyltartrate), and Rubyl (quinine bismuth iodide). As the firm is the largest British manufacturer of mercurials, there is naturally a fine display, including the chloride, and oxides for anti-fouling paints. Hypnotics and analgæsics, anæsthetics and alkaloids vie in interest with bismuth salts of all kinds, molybdic acid and ammonium molybdate for testing steel, lead arsenate for controlling insect pests, potassium cyanide in various strengths, lithium salts, and guaiacum, jalap and scammony resins. An interesting exhibit.

Thomas Tyrer and Co., Ltd., naturally specialise on their stand in a representative selection of the well-known "Sterling" brand of pure and technical chemicals. Bismuth salts, bromides, ethers, iodides, mercurials, phosphates and phosphoric acid, preservatives, siccatives, antifouling compositions and many more besides, are produced for industry, and there are other fine chemicals for analysis, assaying, pharmacy, photography, vulcanising and a large number of industries. It is of interest to note, as an indication of the firm's progressive character, that it is prepared to consider proposals for the initiation of new manufactures, and yet the list of "Sterling" brand chemicals covers 28 closely printed pages!

The exhibits of Duncan, Flockhart and Co. are classified under anaæsthetics, organotherapy, and vaccines and protein therapy, which include many fascinating products of modern science. The white label chloroform—the original chloroform—ether, ethyl chloride represent the anæsthetics; adrenalin, pituitary fluid, thyroid gland represent organotherapy, and the vaccines, tuberculins and the peptone treat-

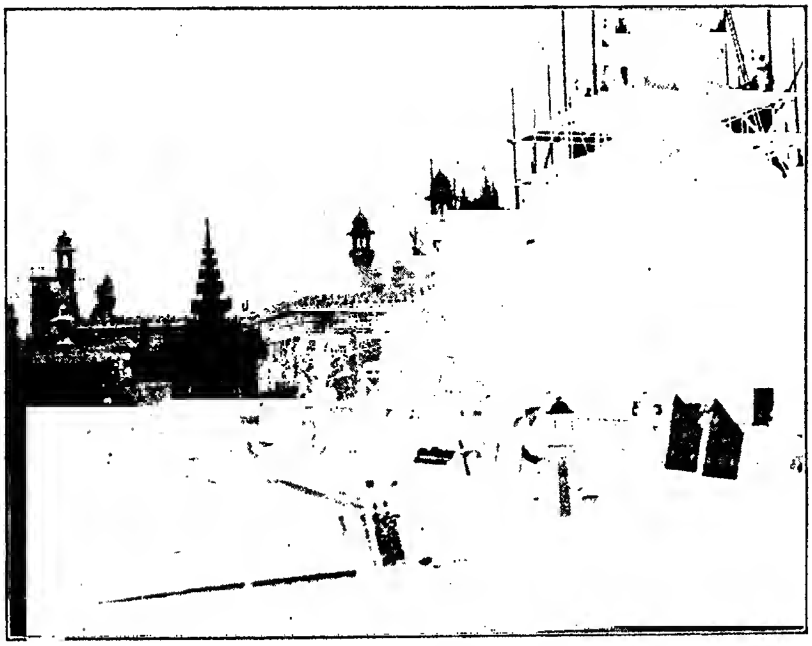
ment, innocent enough in appearance, mean the relief of so much human misery, but one wonders if the part played by the chemists who have made their production possible is yet generally realised by the public. Progress is being made, however.

Those suffering from "nerves" should not fail to acquire comfort from the delightful array of sedatives exhibited by Whiffen and Sons, Ltd. Atropine, hyoscine and hyoscyamine, bromides of many kinds, and caffeine, are there to sooth the troubled breast, transparent camphor lies in wait for minor ills, and iodides, produced by this firm for over 50 years, offer the alarming possibility of the mass treatment of goitre through the local water board. That interesting salt, tartrate of nicotine, flaunts beside the salicylate, and common nicotine and iodine, iodoform, essential oils, salicin and various quinine salts each add their note, culminating in an ominous bulk display of strychnine. As a contrast there is vermilion in shades from pale orange to deep red, a product made by one branch of the firm for over two centuries.

Characteristic stands are those of Burroughs, Wellcome and Co., Ltd., who have an attractive display of their well-known products, whether of the "Tabloid" brand of photographic chemicals or of medicinal and toilet specialities. Everything done by this firm is marked by precision and thoroughness, qualities which are reflected in their many and varied exhibits.

Johnson and Sons, Manufacturing Chemists, Ltd., exhibit their "Scales" brand of photographic preparations, some of which were developed during the war to replace products previously obtainable only from Germany. Many other chemicals are exhibited, of course, and the stand will well repay a visit.

Everyone will wish to see the large revolving centrepiece containing photographs of Port Sunlight at the stand of Lever Bros., and if information is wanted, experts are there to advise on the use of numerous soaps and cleansing agents, whilst interesting information can also be obtained in booklets to be read at home. Sunlight, Lifebuoy, Lux and Vim— the names explain themselves, and if Twink is possibly new, the wide range of Twink colours for all textiles is illustrated by a novel device. On the same stand Messrs. R. S. Hudson's exhibit their well-known soap and other products.



India and Burma

One cannot escape the exhibits of soap, and the Erasmic Co.'s stand makes one feel how much one's ablutional and tonsorial habits have fallen short of the ideal. Those who visit this and some other stands will come away heavily laden, if lighter in other ways. At another stand, that of D. and W. Gibbs, most of the space is given up to the manufacture (excluding boiling) of toilet soap, using actual works machinery run by a full staff. Then another stand consists solely of the Ofome cleanser, which is designed to combine the properties of soft soap, household soap, cleaning powders and benzine, and so to reduce the cost and labour of cleaning. The stand of J. J. Rigby shows many soaps—a soft soap for waste spinners, a pure vegetable oil soap for

textile works and a variety of household soaps for various purposes. On the stand of Joseph Watson and Sons are to be seen the well-known Matchless Cleanser, Nubolic disinfectant soap, various toilet soaps and washing powders, and a display of technical oils and feeding cakes produced at the firm's seed-crushing mills.

Amongst other firms that are exhibiting mention must be made of J. and E. Atkinson, Ltd., who show Eau de Cologne representing a century's experience in manufacture, soap, perfumes, and various aids to beauty.

The Section devoted to Pottery and Glass provides some very fine exhibits of ceramic wares and glass products. Amongst the last-named exhibits, Messrs. Chance Brothers and Co., Ltd., are showing a set of heat-resisting laboratory glassware and a range of samples of scientific glasses, such as optical and spectacle glass and heat-resisting ware, in addition to all types and descriptions of window-glass.

Bottles for everyone and for every use are to be seen in the exhibit of the United Glass Bottle Manufacturers, an interesting feature being the crystal show jars in the space occupied by Webb's Crystal Glass Co., Ltd. The combination of brilliance and attractive shape that characterises these jars reflects much credit on the company, whose works, known as the Edinburgh and Leith Flint Glass Works, are well situated for supplies af fuel and raw materials and so can supply in quantity both quickly and economically.

In the Rubber Industries Section, most of the well-known manufacturers are represented. On the stand of the North British Rubber Co., Ltd., is a selection—completeness would be almost impossible—of the company's products. Tyres jostle with belting of every sort and snakes of hose lie slimly coiled, and there are samples of many charming articles made from vulcanite. Mechanical goods of every description are shown, and there are specimens of rubber tiling, matting, mats and "paraflor" floor covering. Near by is housed the Peachey Process Co., Ltd., which is exhibiting the numerous and growing applications of the process from which the company takes its name.

In another part, the Thermal Syndicate is showing an interesting series of Vitreosil products. Vitreosil is, of course, pure silica fused by an electric process, and there seems little limit either to the forms in which it can be made or the uses to which it can be put. Gas globes, lighting bowls and many decorative articles in Vitreosil are to be found anywhere, and there are Vitreosil concentration plants for sulphuric acid, and plants for many chemical manufacturers. For the laboratory there are Vitreosil combustion and pyrometer tubes, tubes for gas analysis and ordinary tubing, plates, boats, evaporating dishes, beakers and many other indispensable articles. It is of interest to note that Vitreosil, free from bubbles and striæ, can now be obtained for optical work.

Nobel Industries, Ltd., occupy a bay that is an exhibition in itself and the huge model landscape that illustrates the usefulness of Nobel products and their influence on every day life will prove a great attraction. In addition to explosives, there are gold and aluminium paint, manufactures of non-ferrous metals, leather cloth, gas mantles, and various engineering products to show the wide range of industry covered by this important company.

The stand of Necol Industrial Collodions, Ltd., forms part of the Nobel Exhibit and furnishes an illuminating comment on the possibilities of collodion lacquers and enamels for use by the leather, furniture, metal and engineering trades. The lacquers are air-drying, water-white liquids and, like the enamels, can be applied by spraying, dipping or brushing. Other exhibits are "Necoloidine," a pure collodion for microscopy and photography, and Necol coloured and frosting lacquer for application to electric lamps.

The visitor who neglects the Section devoted to Food Products and Beverages will be indeed unwise, for there, amidst an array of toothsome biscuits, and with sauces to the right of 'em, and condensed milk to the left of 'em, is the stand of Baker, Perkins, Ltd. Those who are aware that Messrs. Baker, Perkins make machinery for the manufacture of soap and paint must not draw any hasty conclusions, for a visit to the firm's works at Peterborough would reveal drying plant, sifters, grinders, mixers, mills of all kinds, and many varieties of chemical plant either in the making or about to be dispatched. Let the doubter, with memories of certain meals, pass on, reflecting on the mysteries of Providence.

In the Scientific Instruments Section there are exhibits of all kinds of instruments, amongst which mention may be made of the balances shown by those well-known makers L. Oertling, Ltd., whose exhibit includes balances and weights, both chemical, assay and bullion, as well as hydrometers, petroleometers, saccharometers and other indispensable instruments. There is also the ingenious Otis King calculator. This calculator, shown by Messrs. Carbic, Ltd., is made in two models, one which solves any question of compound multiplication and division or problems involving both, whilst the other will solve all mathematical problems that can be solved by an ordinary slide rule and is equivalent to a slide-rule 66 in. long, but is more accurate. The instrument is simple in operation and can be carried in the pocket, as it is practically indestructible and weighs only four ounces. Full particulars are given in leaflets, to be obtained at the stand.

One approaches the different stands with varying feelings, but that of Johnson, Matthey and Co., Ltd., cannot but induce a deep sentiment of respect. Are they not the lordly people who abound in gold and silver and precious metals, while we possess neither aniseed nor cummin. Do not they work up glittering masses of platinum or gold or silver into apparatus that will reveal—let us hope accurately—all kinds of dark secrets in the laboratory or produce the most entrancing perfumes. And is it not this firm that, in a modest notice, offers to supply "Salts and Compounds of the Precious and the Rarer Base Metals," and invites inquiries. Invites inquiries! Memory recalls a small boy who wished to be an engine driver. He had not heard of Johnson Mattheys. It is well to tread lightly: the visitor is in the Jewellery Section.

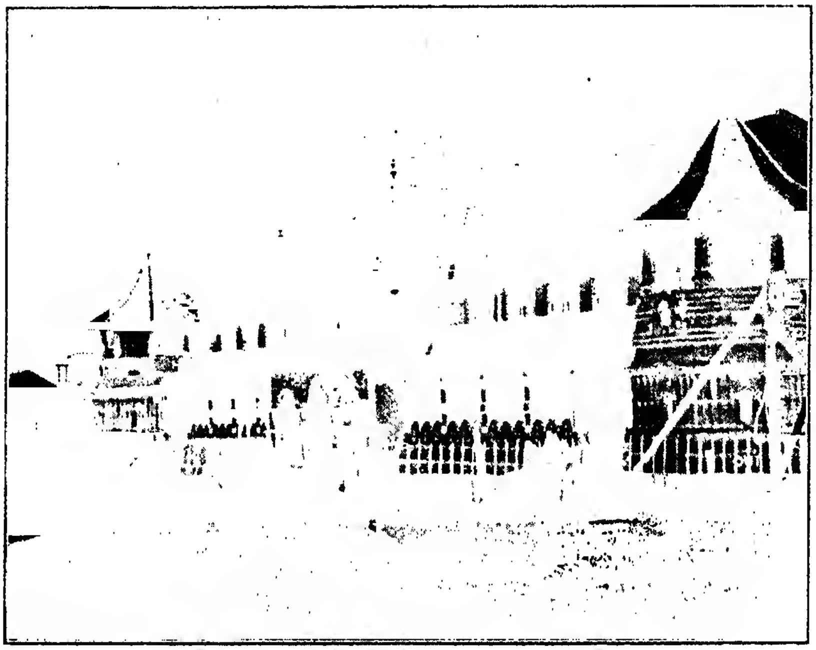
Palace of Engineering

Sheer numbers alone make it impossible even to mention all the firms exhibiting in the Palace of Engineering. An attempt, far too limited by space and time, will be made to draw attention to a few of the exhibits, with the pious hope that it will be possible to do more at a later date. The specialities at the stand of Attwater and Sons can be summarised as "insulating and packing materials" and nearly anything that could be mentioned under these heads will be found there. From india-rubber valves, sheet, washers and pipe, to belting, from mica and vulcanised fibre, to bakelite and ebonite products, all these and more are to be seen in fact or in figure at Messrs. Attwater's stand and many are sure to see them.

Sir W. H. Bailey and Co., Ltd., make a wonderful variety of plant and seem to supply with equal facility anything from a small pump to large and complicated turret clocks, though they modestly describe themselves as pump, valve, testing machinery and recording instrument makers. Some of their products on the stand include pumps, compressors, vacuum pumps for chemical works, valves, guages and recording instruments.

If any information on refrigerating and ice-making plants is required, this can be obtained at the stand of Messrs. J. and E. Hall, Ltd., of Dartford. Cooling is quite a common operation, but it is not always efficiently conducted, and there are many opportunities in the chemical industry for the installation of plant such as that supplied by this Dartford firm. The application of refrigeration is by no means confined to the storage of food materials and large plants by Messrs. Hall are already in use by some large industrial undertakings. To what extent their plant can be used can be guaged by a visit to their stand.

Messrs. David Moseley and Sons, Ltd., are exhibiting with the group organised by the Society of Motor Manufacturers and Traders, so that tyres are predominant. But there is a skeleton sample show of other manufacturers such as hose, all sorts of mechanical goods, and vulcanite tubing. Standard pumps have long been made by this firm in vulcanite and vulcanite pumps of the type made 10 years ago are still working successfully.



Ceylon

Another exhibitor in the Motor and Cycle section is Bell's United Asbestos Co., Ltd., known to readers of this *Journal* as the manufacturers of Poilite and Everite products, such as asbestos cement, sheets, whether flat or corrugated, tiles, coping ridging and other constructional materials. In the production of these materials the company uses solely standard Portland cement of British manufacture supplied by the Cement Marketing Co. The stand of this last company is to be found in the Building Materials section of the Palace of Industry.

One cannot claim any professional interest in diving tanks, but one is being used for demonstrations by Siebe, Gorman and Co., though to readers of this *Journal* they will be known as

manufacturers of air compressors with a wide range of capacity, of gas analysis apparatus, of smoke helmets, and of oxygen breathing apparatus. A trusting person will give demonstrations with a self-contained breathing apparatus in a poison gas chamber every day, and as visitors are sure to want to see this and the diving tank, they will also see the rest of Messrs. Siebe Gorman's unusual exhibit.

The "Geryk" vacuum pump is shown by the Pulsometer Engineering Co., Ltd. The interesting point about these pumps is that they are capable of evaporating at very low temperatures; thus, for instance, aqueous moisture can be evaporated at a temperature as low as 0° F., and as evaporation at low temperatures is at times of cardinal importance in various chemical operations, the exhibit is sure to attract a good deal of attention.

The Semet-Solvay and Piette Coke Oven Co. has provided an exhibit which consists of a half-size model of a "Piette" vertical flue oven in silica construction and a model of a modified type of the same oven that may be heated either by producer, blast-furnace, or coke-oven gas, to meet varying demands for surplus gas. There are also two small models of the Standard Semet-Solvay regenerative oven with a number of photographs and drawings of plants built by the firm and its associates.

A friendly cynic said that the best way to find the Palace of Engineering was to follow the Scotch accent. It is true that there are many Scotch exhibitors, and as they long have had a reputation for sound work, one is not surprised to find this in evidence on the stand of Pott, Cassels and Williamson, of Motherwell. One of their specialities is the manufacture of all sorts, types and sizes of centrifugal drying machines, and if more information is wanted, why not visit the stand?

A heavy responsibility weighs on those who manufacture containers that have to withstand pressure and it is surprising that one so seldom hears of accidents due to steel gas bottles and cylinders, used to store a large number of industrial gases, whether compressed air, oxygen, acetylene, nitrous oxide or other gases. Those who control the destinies of the stand of Stewarts and Lloyds, Ltd., of Glasgow, do not seem in any way nervous and offer one an assortment of tubes and fittings for all purposes whether under pressure or not, or gas cylinders full of dangerous gases with as little concern as they provide steel plates and castings or zinc sheets. One cannot but admire this certainty.

Diogenes lived in a tub, so memories of childhood suggest, but he can't have had one made by Messrs. P. D. Mitchell, Ltd., of Dundee. No doubt this firm could provide a suitable barrel for tired and morose journalists, for, according to a polite gentleman, overflowing with information, they can furnish steel containers, kegs, drums and barrels of every description with wonderful patent weldings. Alas, such are beyond the dreams of journalists. . . . but, in any case, think of the English climate!

The Glenboig Union Fireclay Co., Ltd., show a variety of their fire-clay goods and furnish particulars of their different products with advice on how to choose products for use under particular conditions. This firm has the twin advantages of being of old standing and of having at command the best technical assistance, reasons why their products have gained so many awards at home as well as international exhibitions.

Of course, the Mond Nickel Co., Ltd., has a stand in the Palace of Engineering and like this company's other stand in the Chemical Section, it is well worth a visit, the exhibits being of much interest.

It is evident that electrical power is being increasingly used in industry and it is of interest to call attention to the stand of Messrs. Allen, West and Co., a firm which has specialised on the various types of control gear for every kind of electrical control required in chemical works, dye works, and other factories. Particulars of starters, switch gear, resistances, and controllers made by this firm can be obtained at their stand.

The Cambridge and Paul Scientific Instrument Co., though exhibiting in the electrical section of the Palace of Engineering, has numerous other exhibits on other stands in the same building—the exhibits including thermographs, distance thermometers, thread recorders, pyrometers—whilst in the Palace of Industry, there is a thread recorder measuring furnace temperatures in the scientific exhibit, an automatic temperature control outfit on an electric furnace shown by Baird and Tatlock, index thermometers in the working bakery shown by Baker, Perkins, Ltd., and there are other exhibits in other pavilions.

* * *

Thus concludes this hasty and incomplete account of many exhibits of interest to readers of this *Journal*. Omissions are many, but it is hoped to repair these and other errors by articles that will appear in later issues, describing groups of exhibits in detail.

FLUXES AND SLAGS IN METAL MELTING AND WORKING

A general discussion on this subject is to be held on Monday, April 28, by the Faraday Society and the Institute of Metals with the co-operation of the British Non-Ferrous Metals Research Association and the Institute of British Foundrymen. The meeting will be held from 3 to 7 p.m., with an interval for tea, at the Institution of Mechanical Engineers, Storey's Gate, S.W. 1. A general introduction will be given by Prof. C. H. Desch, and there is a programme of some fourteen papers intended to initiate discussion on the various aspects of the subject. The papers deal primarily with the uses of fluxes and slags in the smelting and refining of the non-ferrous metals, but there will be one section dealing with fluxing problems in arc and oxy-acetylene welding. The subject of slag inclusions will also be dealt with. A copy of the complete programme may be obtained from the Secretary of the Faraday Society, 10 Essex Street, London, W.C. 2.

THE FERMENTATION OF CACAO

By A. W. KNAPP, B.Sc.

(*Continued*)

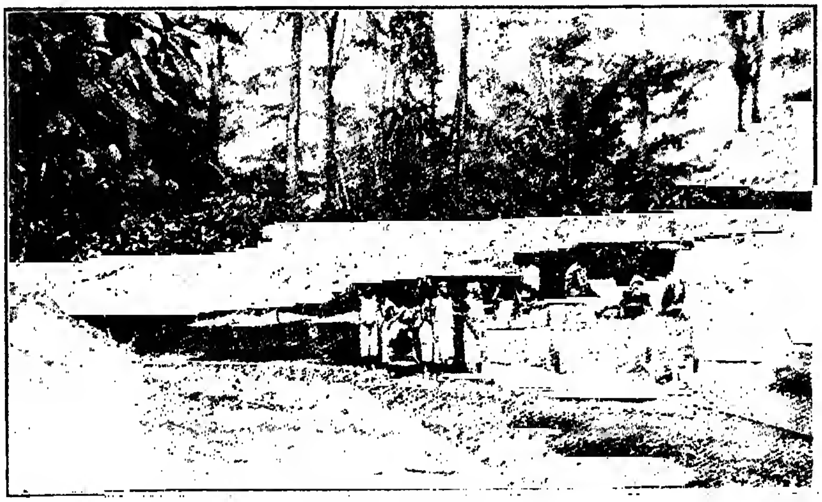
Changes in the Interior of the Bean

Under the skin of the bean there is a soft membrane, the perisperm. The part of this membrane which is on the outside of the cotyledons consists of long polygonal cells up to 60μ in length. The continuation of this membrane between the folds of the cotyledons has a more indefinite structure. On fermentation this membrane gradually loses its structure and in some places disappears entirely. This is in accord with observations of the cacao bean of commerce. Everyone has noted in the rooms in which roasted cacao beans are broken up, that pieces of thin transparent skin, known as "beeswing," float about the room. This is the perisperm, and on examining fermented cacao beans one can usually only discover it at places where it would be at its thickest. Attached to this membrane, on the outside only of the cotyledons, and not in the folds, is the epidermis of the cotyledon, which, in the raw beans, consists of polygonal cells about 20μ in diameter. These cells each contain about nine little angular granules which are about three-quarters the size of the cacao starch, and which stain brown with iodine. These may be aleurone grains. This epidermis appears to be little affected by fermentation.

As the manufacturer only has use for the inside of the bean, and not for the shell, with its small amount of adherent pulp, it is with the changes in the cotyledons that he is mainly concerned.

The cotyledons of the fresh bean as taken from the pod contain about 33 per cent. of water and 37 per cent. of the hard fat, cacao butter. The principal other substances present are starch, albuminoids, tannins, fibre and theobromine.

The microscopical appearance of a section of the fresh Forastero bean is highly characteristic, the most striking feature being that 10–20 per cent. of the cells are full of a violet pigment. The ordinary cells contain starch and fat, but I was unable to find these in the pigment cells; possibly their presence was concealed by the pigment. Where the section has been exposed to the air certain of the cells, which do not contain violet pigment, become brown. If the beans are merely dried, the patches of violet pigment are unchanged, save that driving off the water causes the colour to be deeper and more blue. The curious misty slate colour of a section of an unfermented bean is solely due to the violet dots on a white or brownish background. Examination with a hand lens will readily reveal the pigment.



Transporting cacao-beans from the plantation to the fermentary, San Thomé

Fig. 1

In the fermentation of Forastero cacao as practised in Trinidad, the interior of the bean shows practically no change for the first 48 hours. In a very short time, when the beans have been fermenting about 60 hours, a remarkable change takes place. The isolated pigment patches disappear, and the pigment is evenly diffused throughout the bean. The juice of the cotyledons, formerly neutral, is now acid to litmus, and this acidity changes the violet pigment from blue-violet to red-violet. Even the white germ becomes tinted red-violet. At the same time the interstices in the bean become full of a gummy brown, or brownish-purple, liquid. This liquid I found to contain a multitude of orange-coloured spheres, much smaller than starch grains. They look like cacao butter globules, but do not readily dissolve in petrol.

The temperature at which this rapid and striking change takes place is from 44° C. to 47° C. This is the temperature at which the cacao seed is killed,

and at which, therefore, it becomes possible for the various substances in the bean to come in contact and react. By this time the pulp is acid with acetic acid, and as the skin during fermentation becomes permeable it is reasonable to assume that this acid passes into the bean, and assists in the chemical changes. I have never seen micro-organisms inside the bean. There remains to consider if enzymes assist in the reactions.

The Presence of Enzymes

The following enzymes were found by Brill[7] in cacao beans and pulp :

Enzymes in Cacao Beans

	Pulp	Beans (fresh)	Beans (fermented)
Casease ..	+ ..	+ ..	+
Oxidase ..	++ ..	++ ..	+
Raffinase ..	+++ ..	[illegible] ..	++
Protease ..	+ ..	..	+
Invertase ..	++ ..	– ..	+
Diastase ..	..	..	++

Besides the above, Brill[8] also found an emulsin-like enzyme in the fresh bean (thus corroborating J. Sack.)[9] He showed that lipase, albuminase, inulase, maltase and reductase were always absent. It is curious that he does not mention peroxidase. In testing the dried beans at Bournville we have not found oxydase ; possibly it is destroyed by the temperature of drying or by the absence of water. We find, however, that dried, unfermented beans from Trinidad and Accra contain peroxidase, unless they have been steamed. It would appear that the protease and invertase in the bean come from the pulp. Diastase is developed in the bean during fermentation, and probably aids the production of the dextrin-like liquid in the bean. It should be noted that in correct fermentation of cacao there is not the slightest sign of germination, and that therefore any observed changes are not due to germination but to the action of the enzymes which is made possible by the killing of the seed by heat, possibly assisted by acetic acid. It has sometimes been suggested that the objects of fermentation are to kill the bean and ensure a stable product. But the bean is killed by merely drying in the tropical sunshine, and, contrary to the opinions of many planters and brokers, the unfermented bean, if dry, is perfectly stable, shows not the slightest inclination either to germinate or ferment, and will remain quite unchanged for years.

Oxidation of the Tannins

A very important change which occurs on fermentation and drying is the change of Criollo beans from white to brown, and of Forastero beans from purple to brown or purplish-brown. It is generally agreed that both contain substances generally called "tannins," which, in the presence of an oxidase, go brown. The Criollo beans contain a colourless tannin, and, in my opinion, the Forastero beans contain the same colourless tannin and also the purple pigment, which is a tannin or compound of tannin. With the juice of the fresh undried Forastero bean, whether unfermented or fermented, one obtains a deep blue with ferric sulphate. If oxidation is first allowed to occur, the colour obtained is olive green.

Criollo beans only require two days to ferment. In 24 hours they are several degrees hotter than the Forastero under the same conditions, but as they are frequently only fermented 36 hours, one must conclude that a temperature of 35° C. kills the Criollo bean and liberates the oxidase. Fickendey definitely states, on the contrary, that the devitalising temperature is 5° C. to 10° C. higher than for Forastero. The skin is thinner and therefore probably more easily penetrated by the acid juice of the pulp.

The development of the brown colour is easily seen by cutting through a fresh bean and exposing the cut surface to the air. The change in colour, however, does not readily occur throughout the bean unless it has been killed, whether by high temperatures, as in fermentation, or by freezing (as shown by Fickendey). Further, oxidation by the air cannot occur in a bean containing only 5 per cent. of moisture, although Schulte im Hofe[4] has shown that it occurs in beans containing 15 per cent.

The cacao tannins are soluble in water, but the brown oxidation products are insoluble. It has been suggested that it is the oxidation product of the tannin which gives the characteristic aroma of cocoa and chocolate, but both Sack[9] and Caspari[6] have shown that these coloured bodies are tasteless and without aroma. The action of heat on the oxidised tannins is responsible for the fine chocolate colour of roasted cacao beans, and as the tannins (particularly the purple variety) are unpleasantly astringent in flavour, the greater the oxidation the more the astringency is removed. It would probably be unwise to carry this oxidation process to completion, because the product would then be flat and insipid. The ordinary fermentation and drying appear to allow of sufficient oxidation to give a satisfactory product. The greater the amount of purple tannin the bean contains, the more astringent is the finished product.

Fickendey has shown that carbon dioxide is produced when cacao beans are oxidised. This brings the action in line with the discovery of Bertrand,[13] that the oxidation of tannin and pyrogallol in presence of an oxidase is always attended by liberation of carbon dioxide. It is interesting to compare two of Bertrand's results with that of Fickendey :—

	Oxygen absorbed c.cs.	Carbon dioxide disengaged c.cs.
Bertrand (1) ..	23·3 ..	13·7
(2) ..	29·8 ..	16·4
Fickendey	9·0 ..	4·5

It is a recognised effect of the fermentation of cacao, that the beans become plumper after 5 days fermentation. In my experience such beans are full of liquid and there is no evidence of the presence of any gas. But if oxygen can pass in, then carbon dioxide can readily pass out. Not all botanic varieties "plump up" at the same time. Thus, in one experiment in which Trinidad Criollo and Trinidad Calabacillo were fermented under identical temperature conditions, in five days the Criollo beans were a

much darker brown externally and were as round as eggs, while the Calabacillo were fairly flat.

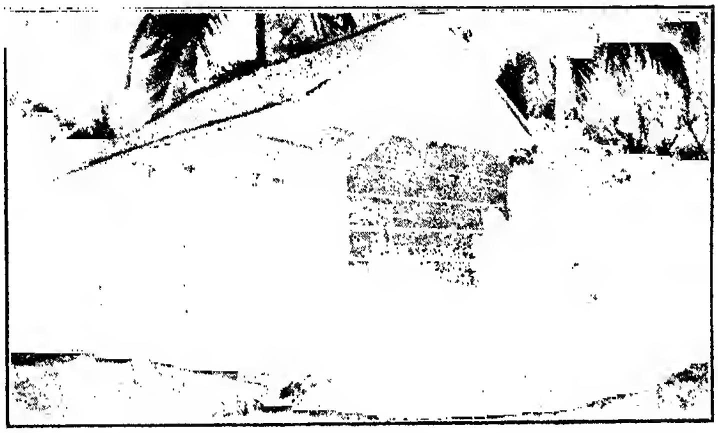
The question of the distribution of the theobromine during fermentation is dealt with in a paper by R. V. Wadsworth and the author.[10]

Drying the Beans

The development of the brown colour continues during the drying. If the beans are heaped on the drying platforms some exothermic action takes place. Thus, after seven days fermentation in a box and one day's exposure to the sun on a tray, some beans were heaped 18 in. high and covered with banana leaves. On the following morning their temperature was 42° C. It is hard to believe that this was due to the continued fermentation of the exhausted pulp, and suggests that the heat was produced by oxidation inside the bean. It is possible that this is a factor in the high temperatures maintained in cacao fermentation.

Fickendey has shown that the oxidase in cacao is destroyed at 75° C. It will be evident, therefore, that it is advisable not to exceed this temperature in the early stages of drying, as may happen when using artificial means. Moulds seldom appear in the fermenting boxes, unless the temperature falls below 34° C., although it is difficult to understand why they do not thrive there. When the beans are put on to the drying platforms mould growth is always liable to occur, and the risk of the cacao becoming mouldy is one of the planter's chief troubles. The help of the bio-chemist is needed here. Hudson[5] recommends that the drying platforms should be covered with sheet copper. This might prevent mould growth, but there would be some risk of the acetic acid in the beans taking up the copper.

Besides the brown colour, a crisp "break" and the presence of air spaces are recognised characters of fermented cacao. There is an appreciable increase in the percentage of mucilage, gum and pectin found in the bean after fermentation, and it may be that the drying of these to brittle solids accounts for the fact that while the unfermented beans when dried have a cheesy consistency, the fermented beans are crisp. The skin of the fermented bean has been expanded, and the cotyledons partially separated by the fermentation, so that on drying the shell remains more or less free and the bean appears open-grained. Although the shell has become permeable to liquids, fermentation actually renders it, on drying, tougher and harder, and less likely to be attacked by insects. The removal of the sugars from the pulp and the saturation of the shell with pectin may account for this.



Small boxes for fermentation of cacao, Trinidad. Note ventilation at top

Fig. 2

Other Methods than Fermentation

Fickendey[12] has suggested that the bean should be killed by freezing, and the pulp removed by washing. In Perrot's[11] opinion fermentation is detrimental, and the beans should be steamed and the pulp removed by dilute alkali. I have tried both these methods on Trinidad cacao, but, apart from the fact that they are more costly than fermentation, they do not produce so good a product. In particular, the characteristic chocolate aroma is lacking in the roasted bean. This raises the question as to whether the pulp is necessary to obtain all the beneficial changes. Below are notes on some experiments I made to determine this :—

Experiments on Skinned Beans

1. *In Dry Air.*—Several pods, unripe, ripe and over-ripe of the Forastero Amelonado type were taken. The beans, deprived of pulp and skin, were maintained at 45° C.—50° C. in a closed space, air being admitted from time to time. After one day the beans became brownish outside, and developed a faint acid and malt-like odour. After two days beans became brown in parts throughout, pigment cells broken down in places, and colour distributed. Acid and malt-like odour. After three days the radicle (or germ) became brown. After three days' drying

the cotyledons were brown, but only changed in parts.

On roasting the beans were only slightly better than unfermented cacao in colour, odour and taste. As these beans tended to dry up during the experiment, and moisture is evidently necessary for fermentation, the following test was tried:—

2. *In Moist Air.*—Similar beans to those above were carefully skinned and maintained at 45°—50° C. in a vessel partially closed with a plug of moistened cotton wool. After two days the beans were darker and browner; the odour was malt-like, and the greater portion of the bean was brown, and most of the pigment evenly distributed. The appearance was that of partially fermented beans, but the odour was different.

3. *Surrounded by Wet Cotton Wool.*—Beans as above after one day, 40°—43° C., and one day, 43°—47° C., began to germinate. (Beans with pulp removed, but skin left on, acted in the same manner.)

4. *Surrounded by Cotton Wool Moistened with 2 per cent. Acetic Acid.*—In one day at 40°—43° C. the beans became very much paler in colour, the whole of the pigment being evenly distributed: the appearance was very like that of ordinary beans after correct fermentation for three days. (Beans with the pulp removed, but with skin left on, acted in the same manner.) These beans on roasting, though excellent in colour, had not the full cocoa aroma and flavour.

The above experiments show that the colour changes usually associated with fermentation can be obtained without the help of the pulp. The product, however, has not the full cocoa aroma. It is evident that the cotyledons themselves contain the oxidase necessary to bring about the colour change from purple to brown. The development of the malt-like odour suggests the presence of diastase. The experiment with acetic acid indicates that the acidity of the pulp plays an important part—it helps to kill the bean, rapidly penetrates the skin of the bean, and aids in the distribution of the colour throughout the cotyledons. The acid changes the colour from blue-purple to red-purple.

The Odour

It should be first mentioned that the characteristic odour of chocolate is not present in the raw bean, but is only produced on roasting. It is absent in the roasted unfermented bean. So far, in experiments made in imitation of fermentation, I have never observed a case where the true chocolate aroma was produced. For example, the experiment mentioned above indicates that treatment with acetic acid does not produce the correct bodies. It may be that enzymes existing in the seed produce the desired change.

The only information we have as to the composition of the essential oil of cacao is supplied by Bainbridge and Davies[6]. By steam distillation of the roasted Arriba cacao of Ecuador they obtained 0·001 per cent. of an oil, about half of which was *d*-linalool, and the remainder mainly amyl propionate, amyl acetate, amyl butyrate, and linalyl acetate. It would be a most useful research to repeat their valuable work on, say, Accra cacao or Trinidad cacoa, because Arriba cacao is different from all other cacaos in its aroma, which is strong and reminiscent of oil of coriander, and because it always consists of a mixture of fermented and unfermented cacao, usually containing 30—40 per cent. of the latter.

Assuming that the essential oil they obtained gives to ordinary roasted cacao its characteristic odour, one can account for the esters by possible reactions in the pulp, but so far no one has suggested the nature of the substance in the bean which is produced during the fermentation, and which *on heating to* 130° C. gives *d*-linalool.

BORIC OXIDE AS A CONSTITUENT OF GLASS

The durability of glass is important whether the glass be used in the home, in the laboratory, or in industry, and perhaps one of the chief factors which contribute towards durability is the content of boric oxide. Indeed, the use of boric oxide in the production of glasses of low expansibility and high durability is one of the most notable recent advances in glass technology. It is thus of considerable interest to record the appearance of a brochure in which the influence of boric oxide as a constituent of glass is discussed and the properties of boric oxide glasses indicated. The brochure (pp. 47) contains a short introduction, followed by a full description of a series of physical and chemical tests on laboratory ware, ending with a summary of the results showing the resistance to various agents—physical and chemical—imparted by varying contents of boric oxide. In conclusion, notes are given showing the use of boric oxide in improving the durability of table glassware and in the production of glass for electric insulators and there is a bibliography of recent papers on borate glasses. In an introduction Prof. W. E. S. Turner vouches for the impartiality of the discussion, which is presented in such a way as to be intelligible to both glassworker and chemist, and points out that the properties of borate glasses deserve to be more widely known to glass manufacturers. One cannot but compliment Messrs. Borax Consolidated, Ltd., on their enterprise in publishing such a useful summary of an important subject and on their willingness to supply copies to those interested.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool. on Wednesday, July 9, 1924, at 11 a.m.

A preliminary programme appears on this page.

In accordance with the provisions of by-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting: Dr. E. F. Armstrong, F.R.S., *President*; Mr. Julian L. Baker, Mr. C. S. Garland, Sir Max Muspratt, Bart., and Sir Wm. J. Pope, K.B.E., *Vice-Presidents*; Mr. John Allan, Prof. J. W. Hinchley, Dr. J. H. Paterson, and Mr. W. J. U. Woolcock, C.B.E., *Ordinary Members*.

Mr. W. J. U. Woolcock, C.B.E., has been nominated for election to the office of President under by-law 19; Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., have been nominated Vice-Presidents under by-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been re-elected Hon. Foreign Secretary.

Members are requested to nominate, on or before May 9 next, fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22.—An Ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if :—

(*a*) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the by-laws.

(*b*) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(*c*) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the by-laws.

(*d*) The nomination form is not received before or upon the day appointed therefor.

(*e*) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. Longstaff,
General Secretary

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

Wednesday, July 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. Presidential Address by E. Frankland Armstrong, D.Sc., F.R.S.; *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

Thursday, July 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*: Annual Dinner of the Society at the Midland Adelphi Hotel.

Friday, July 11. *Morning*: Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

Saturday, July 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

OTTAWA SECTION

A meeting was held in the University Club on March 13, and after minutes of the last meeting had been read and approved, notes on current literature were given by Mr. Connor, who referred to and showed a sample of a new drier—magnesium perchlorate tri-hydrate—which he said was very satisfactory. Dr. Shutt referred to the 11th edition of "Bloxam's Chemistry," and Dr. Macintyre referred to a book on "Clouds and Smokes," by Dr. Gibbs, and described the preparation of synthol by Fischer and Tropsch, which was recently referred to in the Ottawa Press. Mr. Elworthy called attention to the fact that a commercial plant had been erected in Germany for the synthetic manufacture of methyl alcohol.

Mr. Hambly called attention to a recent action of the Commissioner of Patents, which meant that applications for chemical and metallurgical patents would not be examined by a trained chemist. A committee, consisting of Mr. Lathe, Convenor, Mr.

Stewart and Mr. Hambly, were appointed to deal with the matter.

Mr. M. F. Connor then read a paper on the Investigation of Standard Methods of Analysis. In opening his address Mr. Connor stated that chemists owed a very great debt of gratitude to Dr. Hillebrand for the very valuable work he had done on Rock Analysis. A very interesting discussion followed the address, Mr. Stewart, Dr. Macintyre, Dr. Shutt, Mr. Hambly, Mr. Dick and Mr. Robinson taking part therein.

The meeting adjourned at 10.30, and light refreshments were served.

MANCHESTER SECTION

In the account of the annual meeting on April 4 published in the issue of April 11, p. 406, it was stated that "The whole of the committee and officers of the Section were re-elected, there being no occasion for a ballot." This sentence should have read as follows: "As only one nominee for membership of committee was received, the committee, acting according to rule 10 of the Section rules, made additional nominations to fill the vacancies and a ballot was therefore unnecessary. The new ordinary members of committee were Messrs. R. H. Clayton, F. S. Choale, J. R. Hannay, D. M. Paul, J. P. Shenton, F. N. Terleski, and Dr. Schedler."

THE SOCIETY OF DYERS AND COLOURISTS

The annual meeting of the Manchester Section of the Society of Dyers and Colourists was held on April 11, Mr. William Marshall in the chair. The hon. secretary (Mr. L. Thompson) presented his report for the session, stating that the membership of the section is now 407 as compared with 420 last year, being 282 members, 59 associates and 66 junior members for the present year, the comparative numbers for the previous year being 293 members and 135 junior members. There were five vacancies on the committee with six nominations, a ballot therefore being necessary. Messrs. Price and Burr were appointed scrutineers of the ballot papers, and, when they were collected, it was found there was a tie between two of the nominees. A second ballot was then taken, and the following gentlemen were declared elected to fill the vacancies. Messrs. Alfred Edge, S. H. Higgins, William Marshall, W. H. Pennington and L. Thompson. This concluded the business of the annual meeting.

The ordinary monthly meeting, being the last of the session, was then held. A paper entitled "The Identification of Insoluble Azo Colours on the Fibre, and of Azo Pigments in Substance," by Dr. F. M. Rowe and Miss C. Levin, M.Sc.Tech., was read by Dr. Rowe.

Dr. Rowe first reviewed the available methods for identifying azo compounds by reduction with acid stannous chloride, hydrosulphite in neutral or alkaline solution, etc., or by oxidation with fuming nitric acid, etc. Many azo pigment colours were derived from diazotised amino-compounds containing nitro groups, and in such cases treatment with fuming nitric acid afforded the most convenient means for the identification of this portion of the molecule, particularly when only a small quantity of the product was available. This led to the formation of a diazonium nitrate, but it was not clear from the literature whether this reaction was ever accompanied by the introduction of nitro groups into this residue, and if so in what cases. A series of azo derivatives of β-naphthol, therefore, was submitted to this reaction. When the diazotised amine used in the preparation of the azo compound did not contain a nitro group, a nitro derivative of the diazonium nitrate was always obtained. This nitro group usually entered the p-position with respect to the diazonium group when free, or entered the o-position when the p-position was already occupied. When a nitro group was present in the m- or p-position, the unaltered diazonium nitrate was obtained, but when only a nitro group was present in the o-position, a second nitro group was introduced in the m-position with respect to the first. Consequently, it was necessary to take these results into consideration when using this method for the examination of an aryl-azo-β-naphthol.

The diazonium compounds were identified by coupling one-half with beta-naphthol and one-half with β-hydroxynaphthoic acid anilide, crystallising the products and determining their melting points. Owing to the ease with which such compounds are prepared in a pure condition and the wide variation in melting points, this method was recommended for the identification of primary aromatic amines when only a small quantity is available. For this purpose, a table of melting points has been compiled comprising about 150 azo compounds derived from a variety of diazotised amines coupled with β-naphthol and various arylides of β-hydroxynaphthoic acid.

In view of the growing importance of insoluble azo colours on cotton, the extension of the number of bases and the variety of so-called naphthols now on the market, a method has also been devised for the absolute identification of such compounds on the fibre by means of this table of melting points. A pattern of the coloured calico about 2 in. square is washed with dilute ammonia and soap, dried and dissolved in diluted sulphuric acid (80 c.c acid and 20 c.c. water) at 10° C. The clear solution is poured on to ice, the precipitated colouring matter tiltered, crystallised, and its melting point determined.

Finally the means used for the determination of the constitution of Griesheim-Elektron's Naphthol AS-BO, naphthol AS-BS, naphthol AS-G, naphthol AS-RL, naphthol AS-SW, fast black LB base, fast red RL base, fast yellow G base and eight members of the series of rapid fast printing colours, were described.

Dr. R. E. Stradling, M.C., M.Sc., Ph.D., Assoc. M.Inst.C.E., Head of the Department of Civil Engineering, Architecture and Building in the Technical College, Bradford, has been appointed Director of Research of the Building Materials and Construction Research Board under the Department of Scientific and Industrial Research.

CORRESPONDENCE

ATOMIC STRUCTURE

Sir,—In my article on "Atomic Structure" in the issue of March 28, I stated that Bohr, to explain certain spectral anomalies, had resorted to "dividing elliptical orbits into two types *a* and *b*, such that electron transitions only occur from *a* to *b* or *b* to *a*, but never from *a* to *a* nor from *b* to *b*." This too brief statement fails to indicate the distinction between X-ray and optical spectra, *a* to *a* and *b* to *b* transitions not being excluded for optical spectra. It must be remarked that this subdividing device is as incompetent to account for the sodium yellow line doublet as Bohr's original theory, for, if both the "principal" series (3_2) lines and the "sharp" series (3_1) lines are doublets, as demanded by the *ab* device, the 3_2—3_1 transition ought to give rise to a *quartet*, not a doublet for the yellow line. It is possible, however, that the frequency separation of the observed doublet is a measure of the energy difference between the two types of 3_2 orbits, and the finite frequency width of each component of the doublet is a measure of the energy difference of the two 3_1 orbits, each component of the doublet being made up of two overlapping lines of the real quartet.

Bohr has so far not succeeded in attaching any physical significance to the orbits to which the *ab* distinction applies, though he has recently introduced a third quantum number to differentiate between the types, but this number appears to express no more than the *ab* notation. I hope at an early date to be able to indicate the physical difference between the forms of the *a* and *b* types or orbit having the same azimuthal quantum number, and to assign to them a third quantum number not identical with Bohr's third quantum number, and to show that the slight difference in energy of the two types is due to the difference in the third or subsidiary azimuthal quantum number. The form of these orbits was suggested by a point arising in my last article, in which it was inferred that the three 3_2 electrons in a chromic co-ordination compound could be assigned a symmetry little if at all inferior to that of four 3_2 electrons in a corresponding chromous compounds, if the orbits diverged only slightly from circular orbits. Consideration of the possible types of orbit having axial symmetry led to the conclusion that orbits having only axial symmetry were as probable as elliptical orbits having biaxial symmetry, and that elliptical orbits generally could not be orbits in a plane but orbits on an ellipsoid of revolution, relativistic precession, due to transverse mass, being still due to a velocity component at right angles, but also at right angles to the instantaneous orbital plane, the electron thus describing an orbit on a surface of revolution about a fixed major axis. This fixation of the major axis in an atom and the necessity for orbital precession in a small radial domain of the atom removes what has been hitherto probably the chief obstacle in the way of shared electrons in chemical fixed bonds being conceived as moving in orbits common to both atoms, such orbits being impossible with electrons having Sommerfeld-Bohr orbital precession in the orbital plane. The essential difference from the latter theory is that the perihelion of an orbit is fixed in space, and that the "inner loops" of the orbits are described spirally between perihelion and the region near the circular plane containing the rotating latus rectum of the orbit. This spatial form of orbit obviously allows for the facts of chemical double and treble bonds, and indicates a reason for their progressive instability, due to the mutual repulsions of two or more electrons moving in similar orbits oriented at various angles of the common surface of the "oval" of revolution.—I am, Sir, etc., J. D. MAIN SMITH

AN INTERNATIONAL LANGUAGE FOR SCIENCE ABSTRACTS

Sir,—The article by Prof. J. S. Patterson in *Chemistry and Industry* for April 11 again calls attention to a most promising avenue of escape from the language difficulty, an avenue which has been surveyed by various writers from different points of view. In particular, the writer, with H. C. Prideaux, in 1918 made a detailed examination of the pros and cons, and offered many suggestions as to the way in which Latin could be made to subserve the needs of chemistry. A few extracts may not be out of place, since the article in question (*Science Progress*, 1918-1919, **13**, 447) would probably have gained a wider publicity had *Chemistry and Industry* in its present form been available as a medium of publication. In the first place, the question of choosing an international language for chemistry cannot be dissociated from the wider one of an international language for science. In the next place it is evident that the official adoption of Latin as an international language for science abstracts and other communications might well precede its adoption as a "lingua franca" for scientists and the intelligentsia generally—a position which Latin only lost a few centuries ago, but which it does not seem likely to regain. The former use, however, seems to lie within the sphere of practical politics. Other effective rivals are English or one of the synthetic languages. The controversy between Esperanto and Ido seems to rule out the adoption of either. These are colourless languages, whereas Latin is rich in associations to educated Europeans and Americans. "The suitability of Latin as a medium for expressing the ideas of most sciences in their early stages may be abundantly illustrated, *e.g.*, from the works of Copernicus, Newton, Leibnitz, the two Bacons, Linnaeus, Harvey, Gilbert and Napier. As was remarked by Prof. F. Granger in the *Times Literary Supplement* (1918) 'Science in the pages of Descartes and Newton moved easily in a Latin dress, the materials of which were derived from a still spoken but un-Ciceronian tongue.'" A simplified Latin, more akin to that of the Vulgate than to that of Cicero is required. For chemists there is a precedent still lingering in the Latin of the pharmacopœia.

Certain reforms of nomenclature, needed for consistency or elegance, would be undertaken. Thus a revision of the terminations of the elements was suggested. The uniform adoption of "-um" for metals, and a rationing of this termination as applied to other substances in pharmacology; the use of "a" for all oxides of metals. The use of "on" for non-metals including "helion" would probably not be made quite uniform, but another class including phosphorus, oxygen, etc., would be recognised.

Finally, two parallel passages were almost literally translated into simple Latin in order to show how easily such could be readily understood by anyone who had retained traces of an ordinary school education.

The use of Latin would be taken as a compliment by Italy and be acceptable to all Romance countries, including the great South American Republics.

A standardised Latin could hardly fail to improve on any modern language in consistency, clearness, and precision. It would provide an incentive for the settlement of the confusion that prevails at present in the use of the prefixes mono-, uni-, etc., interchangeably; and generally for the expunging of the solecisms which abound in scientific literature, and which somewhat detract from the complete literary culture which should, and could, be characteristic of the utterances of a precise science.

Finally, it might lead to the definition and differentiation of words like "potential" in the interests of the several sciences which employ them, and to the free coinage of new words which are badly wanted on sound lines. The founders of our science being for the most part "free of their Latin" were able to coin words which were in the spirit of the language. We have almost lost this power, and hence are suffering from a severe "currency deflation."—I am, Sir, etc., E. B. R. Prideaux

QUALIFIED AND UNQUALIFIED CHEMISTS

Sir,—The criticisms levelled at the Institute of Chemistry by your correspondent "Iron" would appear to be unreasonable. The Institute was founded as long ago as 1877, receiving its charter in 1885, and anyone entering the profession of chemistry, without taking the trouble to acquaint himself with its regulations or to qualify for its examinations, has surely only himself to blame if he has difficulty in obtaining admission. For the Institute to open its doors to any applicant without evidence of qualification, as your correspondent suggests, would make the Associate diploma of the Institute of small value as a professional qualification.

The idea that chemists outside the Institute could form an opposing society and say that they only were qualified chemists is fallacious. They would possess no charter. In this connexion, however, I would suggest that the Institute, in order to protect itself and its members from the effects of the formation of such opposing societies, which can but have the effect of disintegrating the profession as a whole, should take steps to obtain powers under its charter to confer on its members the right to the distinctive title of Chartered Chemist. This would not only bring the Institute of Chemistry into line with other professional bodies, such as the Institute of Chartered Accountants, the Chartered Institute of Patent Agents, etc., but would also serve, to some extent at any rate, to distinguish a chemist from a pharmacist. The Institute of Civil Engineers, in this manner, has recently obtained for its Associate members and members the right to the title Chartered Civil Engineer, in order to distinguish the qualified engineer from the large number of unqualified persons calling themselves engineers.

The suggestion contained in Prof. Snell's letter is surely a joke. Would the professor, if asked his occupation, reply, "I am a chemor and I practise chemorry"?—I am, Sir, etc.,

John S. Bousfield

HYDROGENATION FLAVOUR

Sir,—I have just received a new publication on "Fats, Natural and Synthetic," by Dr. Myddleton and Mr. Barry.

It seems that writing books is a very pleasant sporting occupation, where the subject is the "game" and the sportsmen are the authors. The manner in which the game tries to seek shelter in the bush is very interesting. Were it not for the peculiar "odour" which it exudes it would have passed off as a piece of very clever work. I wish your readers to compare pages 788–789 and 790 of the August 17 issue of this journal with pages 94 and 95 of this original publication. Perhaps the authors will have something to say regarding their practice in précis writing.—I am, Sir, &c.,

Labor Omnia Vincit

THE DEPILATION OF SKINS

Sir,—If Dr. Ross will be good enough to read my paper a third time, he will find that he has not only failed to understand the elementary part of it, but has also misquoted me.

I shall not call on Heaven to support me, but would like to tell Dr. Ross that I have boiled solutions of gelatin on many occasions, but have never observed any coagulation; it is quite evident that there must have been some effect of dropsical imbibition.

I am greatly obliged to Dr. Ross for calling my attention to this very important point.—I am, Sir, etc., Joseph T. Wood

Nottingham
April 14, 1924

THE ANALYSIS OF LYSOL

Sir,—In the Journal of April 11, A. H. Dodd proposes to estimate cresylic acid in lysol by direct distillation of the mixed fatty acids and phenols. There appears to be no suggestion of absorbing the distillate in caustic soda or the adoption of any other means of distinguishing between phenols

and hydrocarbon oils or other neutral bodies which might be present and which would be returned as phenols according to the proposed method.

It is quite possible to obtain a clear solution of Lysol in distilled water even when 7½ per cent. of hydrocarbon oils are present.—I am, Sir, etc.,

JAS. GIBSON

PERSONAL AND OTHER ITEMS

On the celebration of Founders' Day on May 21, the University of Manchester will confer the degree of D.Sc. on Prof. Niels Bohr.

The *Manchester Guardian* prints a notice from Christiania stating that the Nobel Institute has announced that each of the five prizes awarded during the year 1923 will be of a value of about 117,000 Swedish kroner (about £7,300). The main fund of the Institute now stands at a figure of slightly over 30 million kroner.—Reuter. The nominal value of each of the Nobel Prizes is about £6,500.

The Le Blanc Medal of the French Chemical Society was presented to Prof. T. M. Lowry recently, at a joint meeting of the Société Chimique de France and of the Société de Chimie Physique.

On April 4, the Rt. Hon. Noel Buxton, Minister of Agriculture and Fisheries, laid the foundation stone of the new building to be erected for the Department of Agriculture in Leeds University at a cost of £60,000. On the second floor of the new building will be the Chemical Department, which includes laboratories, lecture rooms, laboratories for research in nutrition, and rooms for microscopy and other special work.

Dr. R. Greydt, who died recently, will be remembered for his work on the estimation of raffinose in sugar-factory products.

Prof. M. R. Grose, head of the chemistry department of Temple University, Philadelphia, died on March 26.

Dr. F. Frank, whose death resulted from an explosion in the laboratory of the Catalytic Chemical Co., San Francisco, was responsible for important developments in the manufacture of gas and carbon black from petroleum and the utilisation of low-grade fuels.

Prof. H. Rössler, director of the Deutsche Gold- und Silberscheideanstalt has died in Frankfort, aged 79.

Reported German-Swiss Dye Agreement

We are informed by the Clayton Aniline Co., Ltd., that the statement, published in the daily Press and quoted in our issue of April 11, p. 391, to the effect that a large number of shares have been exchanged between the Basle colour manufacturers in Switzerland and a large German dye company is not true with regard to the Society of Chemical Industry in Basle, the Sandoz Chemical Works, or J. R. Geigy, S.A.

AUSTRALIA

New Petroleum Distillation Industry

Nearly 10,000 tons of crude oil, the first shipment of oil sent to Australia for distillation, has arrived at Spotswood from the Anglo-Persian Company's fields in Persia. The distillation is being carried out by the Commonwealth Oil Refineries, Ltd.

FRANCE

Mining and Metallurgy

Owing to increasing activity in the steel industry the production of iron ore has risen from 2,034,759 t. in December, 1923, to 2,257,220 t. in January, 1924, when stocks had greatly decreased. During January the mineral production included 14,967 t. iron pyrites, 24,800 t. bauxite, 3,761,687 t. coal and lignite, 196,939 t. coke, 284,048 t. briquettes, 585,978 t. cast iron, 541,022 t. steel. On February 1, 134 blast furnaces were alight, 42 were ready for use, and 43 were under repair or reconstruction. During January, 1,824,465 t. of coal was imported, including 1,105,919 t. from Great Britain, and 151,353 t. of coal was exported, 88,398 t. going to Belgium and Luxembourg. Imports of coke were 333,025 t., 266,697 t. coming from Germany. The export was 22,987 t., while imports of briquettes totalled 89,261 t., of which Germany provided 55,768 t., and exports were 10,212 t.

Sugar and Glucose Industry

The number of factories still working on February 15 1924, was three, the season having finished 91 works. The amount of sugar extracted during the first five months of the 1923–24 season has been so far 43,675,106 kg. During the same period 14 glucose factories produced 11,413,230 kg. of glucose, of which 186,980 kg. has been exported.

The Silk Industry

From a report presented to the Syndicat des Fabricants de Soieries de Lyon, it appears that the production of natural silk is increasing, the figures being approximately :—France, 198,000 kg. (1922), 280,000 kg. (1923); Italy, 3,735,000 kg. (1922), 4,500,000 kg. (1923); Europe, 700,000 kg. (1922), 1,000,000 (1923); China, 8,005,000 kg. (1922), 8,000,000 (1923); Japan, 18,845,000 kg. (1922), 18,000,000 kg. (1923); other countries, 177,000 kg. (1922), 175,000 kg. (1923), making a total of 32,955,000 kg. in 1923. A similar increase is shown in the production of artificial silk, which assumes more and more importance in France. The world production of this silk in 1923 is estimated 30 to 40 million kg., out of which nearly 3 million kg. was consumed in Lyons alone.

GERMANY

German Sugar Production

H.M. Commercial Secretary at Berlin has forwarded an extract from the *Frankfurter Zeitung*, which states that the production of sugar for consumption is estimated at 1,017,378 tons for 1923-24, as compared with 1,310,180 t. in the preceding year. The production of molasses in 1923-24 is estimated at 15,000 t. The sugar content of the beet, according to latest estimates, amounts to 15·31 per cent. on an average, as compared with 15·5 per cent., the October estimate, and 15·4 per cent., the actual average in the last crop year.

REVIEWS

The Vegetable Proteins. By Thomas B. Osborne. Pp. xiii+154. 2nd Edition. Monographs on Biochemistry. London: Longmans Green and Co. 1924. Price 9s. net.

It is thirteen years since the first edition of this work was published: the time which has elapsed has seen so much added to the knowledge of the vegetable proteins, largely owing, it should be said, to the work of Osborne and his school, that the new edition will be warmly welcomed. It is the essence of the now famous Hopkins-Plimmer monographs that the frequent appearance of new editions keeps them up to date.

After dealing with the occurrence of proteins in different parts of plants, the evidence for their chemical individuality is discussed. Not only do these proteins show constancy of composition and properties; they are also proved to be different by the anaphylaxis reaction, which is the best means available for establishing chemical identity. Apparently an almost indefinite number of chemically different proteins exist in plants, but the technique of dealing with them has so far advanced that the separation of two individual proteins from one another is practically perfect.

A lengthy chapter is devoted to the classification of vegetable proteins under the headings of simple, conjugated and derived. Of the former class the best studied are the albumins leucosin found in cereal seeds, legumelin found in peas and beans, phaselin and ricin. Even better known are the vegetable globulins, of which a number are described, some of which are crystalline. The glutelins, of which the glutenin of wheat is the best example, and the prolamins, including wheat gliadin, are of outstanding interest, owing to the influence they have on the vagaries of our daily loaf—a section of chemistry which we are still far from understanding.

Dr. L. J. Henderson contributes a chapter on the relation of proteins to acids and bases, which he concludes by accepting Loeb's views that normal salt formation is the primary phenomenon: the all too early death of Loeb is a very serious loss to chemistry.

Subsequent chapters deal with the solubility, precipitation and denaturing of the proteins, and contain just that type of practical information which is of greatest value to other workers.

The products and the rate of hydrolysis of the vegetable proteins are discussed at some length with the aid of tables and graphs—considerable importance is to-day attached to the partition of the nitrogen in these substances as measured by the elegant method of an American, Van Slyke.

The proteins of green plants are of importance, if only because they contribute large amounts of protein to the ration of farm animals; a chapter is devoted to their consideration, from which it appears that most of it occurs as a hitherto unrecognised type which is unlike any of the proteins of seeds.

The value of the proteins in nutrition is a subject which has almost entirely arisen since the first edition was written—in the interim Osborne and his co-workers, in particular Mendel, have made an elaborate study of this question. The results are summarised in a dozen pages, of which every line is full of interest.

The final chapter deals with the physiological effect of certain vegetable proteins on the animal organism, in particular the toxalbumins. It concludes with some significant remarks on seed proteins in relation to species. Similar proteins are found only in seeds which are botanically closely related, and such differences in the reserve food substances of the seeds must have an important bearing on the development of the embryo, which starts its life, as it were, with chemical processes already established along definite lines.

Altogether the book is a most attractive one and indispensable to all who have to do with plants and their products—it should be studied, too, by every honours student as an outstanding example of method in chemical science. E. F. A.

A Text-Book of Inorganic Chemistry. Edited by J. Newton Friend. Vol. VII, Part I, Oxygen. By J. Newton Friend and D. F. Twiss. Pp. xxv+370. London: C. Griffin and Co., Ltd. 1924. Price 18s.

The field covered by this book is a wide and interesting one. The authors commence with a short preliminary chapter on the elements of the oxygen group, which is followed by chapters on oxygen, its physical and chemical properties, ozone, the atmosphere, water, its physical and chemical properties, composition and molecular complexity, water as a solvent, water analysis and on hydrogen peroxide.

On the theoretical side of the matters dealt with the book is undoubtedly a useful and, on the whole, an able compilation. Those portions dealing with flame, explosion waves in gaseous mixtures, oxidation and with many of the physical properties of water may be mentioned as particularly interesting, and well presented to the reader. Copious references to original work are given in footnotes, and there are excellent name and subject indexes.

Had the authors confined themselves almost exclusively to pure chemistry and physics, there would probably be but little to criticise in their book. They have, however, very naturally, dealt to some extent with technical matters, and their treatment of these leaves much to be desired in many cases. Thus in dealing with the production of oxygen, no indication whatever is given of the fact that there are to-day only two methods of production which are in actual commercial use, namely, by fractionation of liquid air and by electrolysis of aqueous solutions. More attention might well have been devoted to these and less to other processes, mentioned without any critical comment, and of little interest either theoretical or practical. The description of the manufacture by way of liquid air is quite inadequate and by no means up to date, which is a pity as plenty of admirable literature on the subject is quite accessible. The important

technical applications of oxygen are dismissed very summarily in little more than half-a-page, much of which is misleading. For instance, it is stated that oxygen has been added with success to the blast of an ordinary blast-furnace, whereas in fact the commercial advantage shown by the only large-scale experiments yet tried was very doubtful.

The description of oxy-acetylene cutting and welding is also unsatisfactory. The methods of analysis of oxygen are not adequately dealt with, and some of the more usual and effective methods are not even mentioned. It is remarkable that four pages only are devoted to "The physical properties of gaseous water," and still more remarkable that in those four pages neither the name of Callendar nor the term "entropy" appears. In spite of defects the book can be recommended to those able to gather their more technical information from other sources.

Ernest Fyleman

(1) Colloid Chemistry. By The Svedberg. Pp. 265. New York: The Chemical Catalog Company, 1924.

(2) Chimie des Colloïdes et Applications Industrielles. By L. Meunier. Pp. 336. Paris: Librairie J.-B. Baillière et Fils, 1924. Price, bound 40 frs., paper 30 frs.

(3) Manipulations de Chimie Colloidale. By Wo. Ostwald, P. Wolski and A. Kuhn. Translated by Edmond Vellinger. Pp. xviii +201. Paris: Gauthier-Villars et Cie, 1924. Price f. 6·50.

(1) This is an extremely interesting book, the title of which, however, does not correspond very exactly to its scope. A much clearer indication of the ground covered is afforded by the headings of the three principal parts of the work: I. Formation of the Colloid Particle, II. The Colloid Particle as a Molecular Kinetic Unit, III. The Colloid Particle as a Micell, and by the following passage in the preface, in which the author frankly explains the choice of much of his material: "The author is conscious of having, perhaps, given undue space to description of research done in his laboratory at Upsala, but perhaps, in a science like colloid chemistry which is still in an undeveloped state, it is advisable to present as much as possible such phenomena as the author has really experienced." These beautiful investigations, and the book in general, deal with systems in which *the particles can be made visible*, and the sols in which this is not possible, *e.g.*, the proteins, although certainly not inferior in importance, are treated incidentally only, whilst the gels receive fifteen pages in all.

The first part covers the same ground as the author's monograph on "The Formation of Colloids" (this Journal, Vol. XL., 301 R, 1921), but contains much additional matter on silver and silver halide particles in the photographic plate, and on methods of purification. The second part gives an admirable account of the Brownian movement, Perrin's work on the vertical distribution of particles, Smoluchowski's work on the fluctuations in a given volume, the distribution of sizes (the pioneer work on which was carried out at Upsala) and optical methods of investigation. After dealing with Perrin's formula the author remarks: "Porter, in England, and Burton, in Canada, have made experiments that would show that the formula does not hold over a very wide range. . . . . With regard to Porter's experiments, it is quite likely that the sols had not reached equilibrium." This is hardly a complete statement of the case, as Porter gives a rigorous deduction of his formula, which shows, in good agreement with experiment, that at a short distance below the surface the concentration rapidly tends towards a constant value.

The third part of the book treats of "The colloid particle as a micell," the term being defined as "the particle together with its surrounding or adsorbed molecules and ions and probably a part of the surrounding liquid or gas." The subjects to be covered include adsorption, the electric properties, coagulation and peptisation, and the gels; a plethora of material necessitating somewhat condensed treatment, as this section is shorter than the preceding ones.

The style of the book is remarkably simple and clear, and the author remains lucid in dealing even with those difficult portions of the subject which are his particular delight. The volume—one of the American Chemical Society's series of monographs—is handsomely produced, but a great part of the mathematics appears to have been entrusted to compositors unfamiliar with this class of work.

(2) The plan of this work, which forms one of a series of "Grandes Encyclopédies Industrielles," is interesting and original. The author's object is to prepare the reader for the study of works dealing with the numerous industries concerned with colloids as raw material, intermediate product or finished article. He therefore devotes the first 126 pages to a brief, but very clear and sound, introduction to the theory of the subject. The second part, entitled "Industrial Applications" is really a short encyclopedia of colloidal materials, grouped under the following headings: Vegetable and animal fibres, and cellulose derivatives; artificial dyestuffs, and the practice and theory of dyeing; albumin, gelatin and casein; carbohydrates, including starch, gums and mucilages; tannins and tanning; soaps and emulsions; rubber, latex and vulcanised rubber; clays and soils. These chapters contain a large amount of information which, as far as the reviewer is competent to express an opinion, is sound, useful and shows every sign of having been critically sifted and selected. The book ought to be equally useful to the technical man without special knowledge of colloid chemistry, and to the colloid chemist who may be called upon to apply his theoretical knowledge to practical problems.

(3) This work is a translation, without additions or omissions, of the fourth edition of Ostwald's well-known Praktikum (for review of first edition see this Journal, XXXIX, 263 R, 1921). The translation is careful and competent, and its publication is to be welcomed in view of the somewhat detached attitude which eminent French workers in this field have so far taken up towards its development elsewhere.

Emil Hatschek

THE RECOVERY OF NITRATE FROM CHILEAN CALICHE, CONTAINING A VOCABULARY OF TERMS, AN ACCOUNT OF THE SHANKS SYSTEM, WITH A CRITICISM OF ITS FUNDAMENTAL FEATURES, AND A DESCRIPTION OF A NEW PROCESS. By A. W. ALLEN. Pp. XVI. 50. London: Charles Griffin and Co., 1921. Price 6s.

The purpose of this booklet, published three years ago, is to point a way to a more economical and efficient process for the extraction of nitrate from caliche, including low-grade material, which is based on the Shank's process of lixiviation at present in use. A description of the Shank's process is first given, occupying about half the book, and this is followed by a statement of the "fundamentals of the Allen process of extraction (patent applied for)." This consists in passing a solution or other solvent through a homogeneous mass of caliche which has been dry-crushed to such a size that no appreciable movement of borra (slime) takes place in the direction of percolation. The strong solutions are passed to the precipitation or crystallisation section; the weaker solutions are preferably reheated and used as solvent. The question of evaporation is considered, including vacuum and spray methods. No details of actual experiments or works trials are given.

In many quarters the preparation of nitrate from caliche is regarded as a dying industry. Synthetic methods have made giant's strides of late years, and the problem of the future economics of Chilean nitrate is evidently in the author's mind when he refers to "disquieting rumours" as to the success of synthetic methods. As a contribution to the great problem of fixed nitrogen supply his book would seem to be too little based on actual works achievement to be of much interest to the general reader.

J. R. PARTINGTON

FUEL OILS AND THEIR APPLICATIONS. By H. V. MITCHELL. Pp. xii+171. London: Sir I. Pitman and Sons, Ltd., 1924. Price 5s.

This little book, written in concise and colloquial language without being overburdened with chemical and engineering formulæ, should prove of practical utility to all interested in the application of fuel oils for commercial purposes.

The author illustrates and explains the uses of a wide range of typical burners and oil-burning installations.

Chapter 4, in particular, should be of use to the works' manager and works' engineer, as it not only deals with calorific values in a chatty manner, but draws particular attention to the necessity and the means of ascertaining and overcoming waste in factory plants.

Far too much, perhaps, has been made of colloidal fuel, which presumably the author had to notice in passing, but he gives up almost a chapter to it and draws attention to it in his preface. He also quotes the *Journal of the Institution of Petroleum Technologists* as his authority for a paper on the subject by Messrs. Bates and O'Neill. No such paper has, in fact, been published by the Institution of Petroleum Technologists in their Journal. The author, in dealing with colloidal fuel, seems to be a little inconsistent, having regard to his very necessary and apt hints on the removal of water and solids from oil, on p. 117.

N. A. ANFILOGOFF

PHOTOGRAPHY AS A SCIENTIFIC IMPLEMENT. A Collective Work by various Authors. Pp. viii+549. London: Blackie and Son, Ltd., 1923. Price 30s.

There seems to be no limit to the applications of photography; whether in the domains of criminology or of astronomy, in the recording of events or of physical phenomena, or in the study of metals or disease-carrying organisms, photography is sure to be wanted on occasion, to furnish easily, quickly and accurately, the impartial record. For some time a general survey of the applications of photography has been lacking and in publishing the book under review, Messrs. Blackie have done good service. In it fourteen different chapters have been contributed by as many different authors, and a wide field is surveyed, the following subjects being covered: History of photography, by C. R. Gibson; elementary optics of photography, by Dr. S. E. Sheppard; photographic optics, by Prof. A. E. Conrady; theory of photographic processes and methods; astronomical photography, by C. R. Davidson; application of photography in physics, by Dr. H. Moss; photography in the engineering and metallurgical industries, by J. H. G. Monypenny; photomicrography, by Dr. G. H. Rodman; colour photography, by W. L. F. Wastell; and other authors contribute chapters on photographic surveying, aeronautical photography, photography applied to printing, the technics of kinematography, and the camera as witness and detective. Of particular interest are the excellent review—though not without signs of its origin—of the theory of photographic processes and methods by Dr. Sheppard, and the equally good chapter on photography in engineering and metallurgy by Mr. Monypenny. The optical sections are also satisfying, and throughout the provision of references to the literature is a useful feature. The history of photography and colour photography are hardly treated with sufficient fulness, though useful outlines are given, and space could well be found for this purpose by condensation of the chapter on photomicrography. As a whole the book is excellent and can confidently be recommended.

The Faraday Medal of the Institution of Electrical Engineers will be presented to Dr. S. Z. de Ferranti on April 24, at 6 p.m., when Mr. G. Semenza of Milan will deliver the Fifteenth Kelvin Lecture, and will take as his subject "Kelvin and the Economics of the Generation and Distribution of Electrical Energy."

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Anglo-Persian Oil Company

Replying to Mr. Ormsby-Gore, the Prime Minister said that the Government had no intention whatever of selling the Government holdings in the Anglo-Persian Oil Company. Although he was unable to bind his successors in office, he did not consider that any Government would be justified in parting with the control of the company without the approval of Parliament.—(Apr. 14.)

Fuel Research Board

In a written answer to Sir H. Brittain, Mr. Trevelyan stated that the Fuel Research Board was established in February, 1917. The expenditure by the Department of Scientific and Industrial Research on the work of the Fuel Research Board up to March 31, 1924, amounted to £195,480. The premises of the Fuel Research Station at East Greenwich were provided and maintained by His Majesty's Office of Works; the expenditure by that Department on the station up to March 31, 1923, amounted to £203,352.—(Apr. 14.)

COMPANY NEWS

THE ENGLISH BEET SUGAR CORPORATION, LTD.

This company has been registered as a public company with a nominal capital of £500,000 in 50,000 Six per cent. cumulative participating preference and 450,000 ordinary shares of £1 each, to adopt an agreement with the English Beet Sugar Corporation, Ltd., and the liquidators and to carry on the business of cultivators of sugar beet, and other produce.

HADFIELDS, LTD.

The directors of this company have decided to recommend a dividend for the year of 4 per cent., less tax, on the ordinary shares. In the previous year the company distributed 5 per cent.

KENYA AND UGANDA AS SUGAR EXPORTERS

Until recently some 3,000 tons of sugar have had to be imported yearly to supply the needs of Kenya and Uganda. These countries are now, however, self-supporting, and in the immediate future are likely to have an annual exportable surplus of about 10,000 t., for three modern plants for the treatment of local cane have recently been erected. The Nanji Kalidas Mehta factory in Uganda, now being erected, will produce about 6000 t. of sugar per annum, and the two mills in Kenya should between them manufacture approximately the same quantity, or a total of 12,000 t. To enable this young industry to compete in oversea markets the Uganda Railway is being urged to grant specially low rates.—(*S.A.J.I., Mar.*, 1924.)

REPORTS

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN PARAGUAY, SEPTEMBER, 1923. *By* F. W. PARIS, *H.M. Consul, Asuncion. Department of Overseas Trade. Pp.* 22. *H.M. Stationery Office*, 1923. *Price* 9*d*.

The increased volume and value of exports from Paraguay in 1922 shows that the effect of the political unrest was no more severe than the earlier effects of war conditions (*cf. Chem. and Ind.*, 1923, 158).

The timber industry is the most important in the country, and this suffered severely in 1922 from the transport difficulties due to political unrest, and exports were reduced by about £270,000, or 25 per cent. of the usual total. The cattle-breeding industry did well, and exports of tobacco in 1922 were 5020 tons, about 2000 t. less than in 1921. The total sugar production was 3240 t., about the quantity required for home demands. The cotton-growing industry has received a fillip from the shortage in the United States crop, and from propaganda work.

Under the conditions which have prevailed since June, 1922, trade and commerce have merely been marking time. Imports in 1922 were valued at £1,136,958, about 30 per cent. less than in 1921, exports at £1,929,177, somewhat more than in 1921. The United Kingdom is second to the Argentine in the list of countries supplying imports, and the United States comes a close third. Many of the imports from the Argentine are, however, of British origin, obtained indirectly in order to save time.

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN BRAZIL. Dated September, 1923. By E. HAMLOCH, H.M. Commercial Secretary, Rio de Janeiro. Department of Overseas Trade. Pp. 104. H.M. Stationery Office, 1924. Price 3s.

The financial situation in Brazil is described as almost critical, a result of the fall in the rate of exchange due to the costly programme of the Government which went out of office at the end of 1922 (*cf. Chem. and Ind.*, 1923, 82). The effect on trade, however, has not been so serious as might have been anticipated and local industries are flourishing, largely owing to the cost of imports.

The coffee industry has been in a strong position, but cotton growing has suffered by reason of lack of attention to manufacturers' requirements and conditions of cultivation, and efforts are being made to remedy this; in 1922 33,950 t. of raw cotton was exported. The sugar industry has been improving of recent years, the 1922 production being 710,270 t.; Brazilian factories have a capacity of 480,000 t., 350,000 t. being used for home consumption.

The mineral resources of the country have never been systematically exploited. Iron and coal occur abundantly and at last steps have been taken by the Government to encourage their development. There is an export trade in manganese, controlled by the United States; 340,000 t. was exported in 1922. Gold is produced to the extent of about £650,000 annually.

Of manufacturing industries textiles are the most important, beverages, tobacco, and matches forming the other chief items; these four branches account between them for 90 per cent. of the total.

The total value of exports from Brazil in 1922 was £68,578,000 and of imports £49,192,000,000. Of the imports Great Britain supplied 25·8 per cent., the United States 22·8 per cent., Argentine 13·8 per cent. of the exports the United States took 38·6 per cent., France 11 per cent., Great Britain 10 per cent. Germany is rapidly increasing her tonnage of exports to Brazil, and in 1922 it was actually greater than that of Great Britain. Great interest has been shown recently in Brazil by the United States, both on the commercial side and in social questions.

Survey of the Economic and Commercial Conditions in Algeria, Tunisia and Tripolitania. 1922-23. Department of Overseas Trade. Pp. 80. H.M. Stationery Office. 1924. Price 2s. 6d.

For the third year in succession Algerian crops failed in 1922, but in spite of the world-wide economic depression the country has not suffered unduly, and though trade was not flourishing at the time of drafting the report optimism was general owing to the fine condition of the crops.

Imports into Algeria in 1922 were valued at 2007 million fr., against 1791 mill. fr. in 1921, whilst in the first six months of 1923 imports amounted to 986 mill. fr. In 1922 the imports included: animals and animal products, 115 mill. fr.; vegetables and vegetable products, 494 mill. fr.; minerals, 143 mill. fr.; manufactures, 1253 mill. fr. Imports of coal for internal use were 426,457 tons, of iron and steel 38,235 tons, both less than in 1921. An increase in the imports of chemical products occurred in 1922 and was maintained in 1923, owing to the demand from agriculturists.

Exports in 1922 were valued at 1379 mill. fr., agricultural produce being the most important item. Mineral production is going forward. In 1922, 1,046,251 t. of iron ore was produced, 482,304 t. of phosphate of lime, 33,949 t. of zinc ore, 13,789 t. of lead ore, and 6797 t. of iron pyrites.

The trade returns for Tunisia for the years 1917-22 show a steady increase in imports which in 1922 amounted to 856 mill. fr. Exports also increased up to 1921, when they were 673 mill. fr., but fell in 1922 to 445 mill. fr. Most of the trade is with France and Algeria, Italy coming next and Great Britain third, though Great Britain supplies more imports than Italy.

In 1922 the Tunisian cereal crops were poor, but the grape harvest was good. The fishing industry is important, most of the produce being exported. Minerals are also of importance. In 1922, the mineral output included 2,074,131 t. of phosphates, 601,626 t. of iron ore, 6161 t. of zinc ore and 18,935 t. of lead ore.

Tripolitan trade was bad in 1922 owing to internal troubles. The principal exports are esparto (which was only produced in small quantities in 1922), sponges and tunny.

Report on the Economic, Financial and Commercial Conditions in the Dominican Republic. By D. Wilson, Chargé d'Affaires, Santo Domingo City, and in the Republic of Hayti, by J. E. M. Carvell, Chargé d'Affaires, Port-au-Prince. September, 1923. Department of Overseas Trade. Pp. 56. H.M. Stationery Office. 1924. Price 1s. 6d.

The Dominican Republic forms about two-thirds of the island of Hayti. A central range of mountains running east and west divides the country into two well-defined sections. In the northern section tobacco and cocoa are the principal products, in the southern, sugar, coffee, and tropical woods; cattle are raised in both areas. For the past seven years the country has enjoyed conditions of peace and commerce has benefited accordingly. The administration was in the hands of an American Military Government which at the end of 1922 handed over control to a provisional Dominican Government.

Trade in 1922 showed an improvement over 1921, a step in the recovery from the economic crisis of 1920. The value of imports in 1922 was $14,317,497 about 40 per cent. less than in the previous year, though renewed activity was shown towards the end of the period. The value of imports from the United Kingdom in 1922 amounted to 6·82 per cent. of the total, the most important of the items being textiles, machinery, beverages, coal, wire, paints and chemicals. Exports in 1922 were valued at $15,231,355, about 25 per cent. less than in 1921. The principal articles of export are sugar, cacao, tobacco, coffee and other agricultural produce; mining and manufacturing are carried out only on a very small scale.

The Republic of Hayti consists of the western third of the island of the same name. The country stands now on the threshold of a new era, the period of political unrest having been replaced by one of security of life and property maintained by an efficient gendarmerie, the change having been effected by the Haytian American Convention of 1915.

Imports in the year 1921-22 were valued at $12,350,000, the United States supplying 80 per cent., France 9·5 per cent., and the United Kingdom 6·8 per cent. Exports, valued at $10,712,210, were made up principally of coffee, cotton, sugar, logwood, cocoa, and cotton seed and oil. The future of the country depends on its agricultural development, which after a slack period is again progressing.

Report on the Economic and Financial Conditions in Mexico, dated October, 1923. By N. King, H.M. Consul-General, Mexico City. Department of Overseas Trade. Pp. 30. H.M. Stationery Office. 1924 Price 1s.

Economic conditions in Mexico have improved but little since the issue of the last report (*cf. Chem. and Ind.*, 1923, 662). Political developments have played their part in hindering agriculture and reducing production and trade in general.

The mining industry has always taken a leading part in the prosperity of Mexico, and a considerable

increase in the output of metals, especially of gold and silver, in the next few years is indicated. In 1922 and 1923 the country produced 40 per cent. of the world's supply of silver, and in the former of these years occupied the fourth place among gold-producing countries, fifth for copper, and second for lead. The petroleum industry was seriously affected in 1922 by the fall in demands, and as a consequence prospecting for further supplies has been curtailed, even though some wells are nearly exhausted. In 1922 185,070,000 barrels of crude petroleum was produced, the estimate for 1923 being 145,000,000 barrels.

Agriculture is very important in the economic life of the country, though it is reported to have suffered from the breaking up of large estates. Cereals, cocoa, coffee and sugar are the principal crops; in the north-west cotton is grown.

Manufacturing is developed in Mexico, it is sometimes claimed, more than in any other Latin-American Republic. Paper and cement are made on a fairly large scale; for the latter there is an important factory controlled by British interests. Other manufactures include glass, soap, matches, and explosives.

On account of its proximity the United States has a predominant share of the external trade with Mexico; before the war Great Britain came second, and Germany third, but this order is now reversed. Foodstuffs, textiles, and machinery are obtained principally from the United States. Drugs, proprietary medicines, etc., are obtained mostly from the United States, and the better grades from France. Heavy chemicals in demand are chiefly cyanides for the mines, and caustic soda for soap manufacture.

SOUTH AFRICAN MINERAL OUTPUT IN 1923

The following table shows the mineral output of South Africa in 1923:—

		Quantity	Value
Gold ..	(fine oz.)	9,143,403·494 ..	£38,838,711
Silver ..	,,	1,375,536·268 ..	197,054
Osmiridium ..	,,	1,784·183 ..	43,528
Diamonds ..	(carats	2,055,470·00 ..	6,038,207
Coal	(tons)	11,915,497·000 ..	3,714,528
Copper	,,	9,489·090 ..	394,578
Tin	,,	1,424·680 ..	174,147
Arsenic white ..	,,	6·000 ..	290
Iron ore	,,	564·000 ..	230
Lead ore	,,	4,953·055 ..	123,217
Manganese ore ..	,,	432·500 ..	1,584
Vanadium ..	,,	51·250 ..	2,716
Asbestos	,,	8,392·765 ..	121,453
Corundum ..	,,	2,814,739 ..	22,543
Graphite	,,	605·842 ..	1,837
Iron pyrites ..	,,	2,014·000 ..	4,906
Magnesite ..	,,	2,470·000 ..	2,943
Mica	,,	15·674 ..	1,038
Iron oxide ochres etc.	,,	238·500 ..	468
Soda	,,	96;000 ..	1,018
Talc	,,	355·000 ..	1,065

With the exception of gold, silver, diamonds, and coal the figures given represent sales and shipments; those in respect of coal represent sales.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate	3d.—3¼d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide ..	Expected to advance in sympathy with the crude metal.
Golden	5¼d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide ..	4s. per lb.
Carbon Bisulphide ..	£24—£26 10s. per ton according to quantity.

Carbon Black	Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19 £20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s.–5s. 3d. per gall. 60% O.P. market stiffer.
Solvent	5s. 6d.—6s. per gall. 40% O.P Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£49 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7¾d. per lb. Only limited inquiry.
Crude 60's	2s.—2s. 3d. per gall. Market not so good.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Pure	1s. 8d.—1s. 11d. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	7½d.—8d. per gall. according to grade and district. Market again weaker.
Naphtha—	
Crude	8d.—9d. per gall. Better demand. Prices show upward tendency.
Solvent 90/160	1s. 2d.—1s. 5d.
Solvent 90/190	1s. 2d.—1s. 3d.
Naphthalene Crude—	
Drained Creosote Salts	£6—£7 10s. Demand not so good.
Whizzed or hot pressed	£9 10s.—£12 per ton. Not much inquiry.
Naphthalene—	
Crystals and Flaked	£17—£18 per ton.
Pitch, medium soft	52s. 6d.—57s. 6d. per ton. Market steadier.
Pyridine—90/140	22s. per gall. Demand well maintained. Price again advanced.
Heavy	11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 9d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 4d. per lb. Steady demand.
Acid Sulphanilic	10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethyaniline	2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 2d. per lb. d/d.
Monochlorbenzol	£63 per ton.
α Naphthol	2s. 5d. per lb. d/d.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.

m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is lifeless, values remaining at a low level.

Acid, Acetic 80% B.P.	£48 per ton. Market easier.
Acid, Acetyl Salicylic	3s. 5d.—3s. 9d. per lb. Easier.
Acid, Benzoic	Commercial acid 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. lb.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	Prices quoted from 2s. 3d. per lb. down to 1s. 9d. for ton lots. Market rather weak.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 6d. per lb. for quantity. Very weak.
Amidopyrin	13s. 6d. per lb.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. 3d. per lb. Firmer.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market very firm and advancing. Heavy increase in price of bromine.
Potassium	9½d.—10½d. per lb.
Sodium	9½d.—10½d. ,,
Ammonium	10½d.—1s. ,,
Calcium Lactate	Prices vary over a wide range. Good English make can be had from 1s. 7d. to 2s. 3d. per lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. per lb. Little demand.
Guaiacol Carbonate	12s. per lb. for cwt. lots. A cheaper market.
Hexamine	3s. 6d.—3s. 9d. per lb. for foreign makes. Weaker. Without much inquiry. Large stocks.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 3d. per lb. Foreign make.
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate— Light Commercial	£36 per ton net.
Magnesium Oxide— Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol— A.B.R. recryst. B.P.	70s. Strong upward movement due to disappointing Japanese crop.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Very much firmer in view of the rise in the price of quicksilver. Prices have been advanced by 6d. per lb.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	2s. 3d.—2s. 9d. per lb. for carboys.
Methyl Sulphonal	24s. per lb. neglected.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 4d.—1s. 7d. per lb. in free bottles and cases.
Phenacetin	6s. 3d.—6s. 9d. per lb.
Phenazone	8s. per lb. for cwt. lots. Spot prices much lower than forward offers. Firmer tendency.
Phenolphthalein	7s.—7s. 6d. per lb. Firm.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate— B.P. Crystal	8¾d.—9d. per lb. carriage paid. English make.
Commercial	8d.—8½d. per lb. carriage paid. English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Salol	4s. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite— Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate	Market weak. Powder 2s. 4d.—2s. 9d. per lb. Crystal at 2s. 6d.—2s. 10d. per lb. Flake 2s. 10d.—3s. 4d. per lb.

Sod. Sulphide—		
Pure recryst. ..	..	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous		£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal ..	..	.. 18s. 6d. per lb.
Tartar Emetic ..	..	.. 1s. 4d. per lb.
Thymol ..	..	.. 13s. 6d.—15s. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone	..	12s. 6d. per lb.
Aubepine ..	..	13s. 6d. ,,
Amyl Acetate	..	2s. 9d. ,,
Amyl Butyrate ..	..	7s. 3d. ,,
Amyl Salicylate ..	..	3s. 3d. ,,
Anethol (M.P. 21/22° C.)		4s. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol		3s. 3d. ,,
Benzyl Alcohol free from Chlorine	..	3s. 3d. ,,
Benzaldehyde free from Chlorine	..	3s. 6d. ,,
Benzyl Benzoate	..	3s. 6d. ,,
Cinnamic Aldehyde Natural ..	..	15s. 6d. ,,
Coumarin	..	20s. ,,
Citronellol	..	16s. ,,
Citral	..	10s. ,,
Ethyl Cinnamate	..	15s. ,,
Ethyl Phthalate ..	..	3s. 9d. ,,
Eugenol ..	..	11s. ,,
Geraniol (Palmarosa)	..	35s. ,,
Geraniol ..	..	11s.—18s. 6d. per lb.
Heliotropine	..	8s. 3d. per lb.
Iso Eugenol	..	15s. 9d. ,,
Linalol ex Bois de Rose	..	32s. 6d. ,, Very much dearer.
Linalyl Acetate ..	..	32s. 6d. ,, Very much dearer.
Methyl Anthranilate	..	9s. 6d. ,,
Methyl Benzoate	..	6s. ,,
Musk Ambrette ..	..	52s. 6d. ,,
Musk Xylol	..	19s. ,,
Nerolin ..	..	4s. ,,
Phenyl Ethyl Acetate	..	12s. 6d. ,,
Phenyl Ethyl Alcohol	..	16s. ,,
Rhodinol ..	..	57s. 6d. ,,
Safrol ..	..	1s. 10d. ,,
Terpineol ..	..	2s. 9d. ,,
Vanillin ..	..	25s. 3d.—26s. 6d. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. ..	..	15s. 6d. per lb.
Anise Oil ..	..	3s. per lb. Firmer market forward.
Bergamot Oil ..	..	18s. 6d. per lb.
Bourbon Geranium Oil	..	35s. ,,
Camphor Oil	..	75s. per cwt.
Cananga Oil, Java	..	9s. 9d. per lb.
Cinnamon Oil, Leaf	..	$6\frac{1}{2}$d. per oz.
Cassia Oil, 80/85%	..	9s. 3d. per lb.
Citronella Oil—		
Java 85/90% ..	..	5s. 3d. ,,
Ceylon ..	..	3s. 9d. ,,
Clove Oil ..	..	8s. $4\frac{1}{2}$d. ,,
Eucalyptus Oil 70/75%	..	2s. 3d. per lb.
Lavender Oil—		
French 38/40% Esters		26s. per lb.
Lemon Oil	..	3s 4d. ,,
Lemongrass Oil ..	..	$2\frac{3}{4}$d. per oz.
Orange Oil, Sweet	..	13s. per lb.
Otto of Rose Oil—		
Bulgarian	..	27s. 6d. per oz.
Anatolian	..	23s. 6d. per oz.
Palma Rosa Oil ..	..	19s. per lb. Very short supply.
Peppermint Oil—		
Wayne County	..	21s. 9d. per lb. Again advanced.
Japanese	..	20s. per lb. but very little being offered.
Petitgrain Oil	..	10s. per lb.
Sandal Wood Oil—		
Mysore ..	..	25s. per lb.
Australian	..	21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patent those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before June 9th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—Applications

Burt, Boulton, and Haywood, Ltd., and China. Producing disruptive forces in films of liquid china etc. 8284. Apr. 1.

Douglas and Grant, Ltd., and Laud. Drying-apparatus. 8453. Apr. 3.

Lindner, and Wunderlich and Co. Heat retaining and radiating blocks for furnaces etc. 8436. Apr. 3.

Lodge-Cottrell, Ltd. 8449. See XI.

Marks (Grasselli Chemical Co.). Heating and distilling liquids. 8172. Mar. 31.

Myrop. Mixing, emulsifying, and/or atomising. 8474. Apr. 3.

Schulz. 8540. See IX.

Wood. Drying-apparatus. 8425. Apr. 3.

I.—Complete Specifications Accepted

9798 (1923). Goedecke. See XIII.

18,362 (1923). Marks. See VII.

3306 (1924). Fouard. Filtering-devices. (212,233.)

3782 (1924). Bayer Co. Apparatus for producing intimate mixture between gases and liquids. (213,521.)

II.—Applications

Burrows, Simpkin, Sinnatt, and Slater. Method of freeing coal wash water etc. of suspended solids. 8225. Apr. 1.

Crozier. Fractionation of hydrocarbon oils. 8575. Apr. 4.

Dempster and Sons, Ltd., and Toogood. Retort settings. 8405. Apr. 3.

Donald. Drying peats etc. 8088. Mar. 31.

Heyl. Production of greases etc. from oil shale, coal, etc. 8098. Mar. 31.

Regenerative Coal Gasification System, Ltd., Clark, and Travers. Manufacture of gas from coal etc. 8653. Apr. 5.

Sauer. Manufacture of decolorising carbon. 8655, 8656. Apr. 5.

Wilson. Composition fuel. 8602. Apr. 5.

II.—Complete Specifications Accepted

26,114 (1922). Lewis. Molecular conversion of hydrocarbon oils and separation of products. (213,295.)

1646 (1923). Davies. Carbonisation and/or gasification of fuels. (213,363.)

III.—Application

Crozier. 8575. See II.

IV.—Application

British Dyestuffs Corporation, Ltd., and Hodgson. Manufacture of azo dyestuffs. 8268. Apr. 1.

V.—Applications

British Celanese, Ltd., and Ellis. Treatment of products etc. made with cellulose derivatives. 8562. Apr. 4.

Burlin. Removing ink etc. from liquid used in treatment of waste paper. 8186. Mar. 31.

Classen. Manufacture of cellulose-containing solutions. 8371. Apr. 2.

Green. Manufacture of cellulose acetate. 8435. Apr. 3.

Loewe. Spinning artificial silk. 8177. Mar. 31. (Ger., 3.4.23.)

Toman. Process for desizing and degumming fibres etc. 8558. Apr. 4. (Fr., 4.4.23.)

V.—Complete Specifications Accepted

29,254 (1922). Levy. Production of artificial filaments. (213,300.)

10,990 (1923). Koch Kommanditges., and Runkel. Producing half-stuffs and cellulose for the manufacture of paper pulp and paper. (213,447.)

VI.—Applications

Blicquy and Callebaut. Vats for treatment of textile fibres. 8391. Apr. 3.

Thies. Suction-dyeing textile materials. 8454. Apr. 3.

Wheelwright. Production of printed fabrics. 8191. Mar. 31.

VI.—Complete Specification Accepted

471 (1923). Calico Printers' Assoc., and Fourneaux. Treatment of cotton fabrics. (213,353.)

VII.—Applications

Fabrique de Soie Artificielle de Tubize Soc. Anon. Production of concentrated acetic acid from aqueous solutions thereof. 8375. Apr. 2. (Ger., 4.4.23.)

Klopstock, and Neumann. Production of potassium carbonate. 8245. Apr. 1.

VII.—Complete Specifications Accepted

26,000 (1922). Nitrogen Corp. Synthesising ammonia. (186,912.)

18,362 (1923). Marks (Carbide and Carbon Chemicals Corp.). Purifying chlorine and other corrosive gases. (213,486.)

IX.—Applications

Goffart. Artificial marble, granite, etc. 8143. Mar. 31.

Schulz. Production of acid-proof coating for concrete vessels. 8540. Apr. 4.

IX.—Complete Specifications Accepted

5339 (1923). Tolmer. Preservation of wood. (194,683.)

11,358 (1923). Eaton. Substitute for wood etc. (213,468.)

19,725 (1923). Minache. Building-material. (213,495.)

X.—Applications

Aarts. Producing pig-iron or steel in blast furnaces. 8478. Mar. 31. (Ger., 8.5.23.)

Jensen (International Metal Products Co.). Production of ingot iron. 8250. Apr. 1.

Jensen (International Metal Products Co.). Metal-degasifying process. 8251. Apr. 1.

Symonds. Flux for brazing iron etc. 8440. Apr. 3.

X.—Complete Specifications Accepted

78 (1923). Taplin, and Metals Production, Ltd. Leaching of copper ores containing slimes. (213,343.)

1603 (1923). Basset. Direct reduction of ores, particularly iron ores. (194,280.)

15,230 (1923). Leroux. Utilisation of old metals containing aluminium. (206,811.)

XI.—Applications

British Electrical and Allied Industries Research Association, and Flight. Electric insulating material. 8482. Apr. 3.

Lodge-Cottrell, Ltd. (International Precipitation Co., Inc.). Electrical precipitation of suspended particles from gaseous fluids. 8449. Apr. 3.

XI.—Complete Specifications Accepted

3511 (1923). Armitage. Electric accumulators. (213,380.)

12,243 (1923). Katatani. Electric resistance materials. (197,340.)

13,967 (1923). Rhodin. Electrolytic separation with fused electrolytes. (198,376.)

22,803 (1923). Metropolitan-Vickers Electrical Co. Electric cells. (204,694.)

XII.—Application

Vidal. Soaps and detersive preparations. 8235. Apr. 1.

XIII.—Applications

Dowson. Varnish. 8158. Mar. 31.

Fairweather (Magnetic Pigment Co.). Preparing pigments. 8091. Mar. 31.

XIII.—Complete Specification Accepted

9798 (1923). Goedecke (Eberlein). Manufacture of decolorising earths and body colours. (213,438.)

XIV.—Applications

Bateman. Rubber solutions or cements. 8096. Mar. 31.

Calvert. Rubber compounds. 8080. Mar. 31.

XIV.—Complete Specification Accepted

12,373 (1923). Jackson (New Jersey Zinc Co.). Manufacture of compounded rubber. (213,454.)

XV.—Complete Specification Accepted

19,294 (1923). Moeller. Manufacture of tanning extract. (213,493.)

XVII.—Application

Stoffen. Continuous deposition of tricalcium saccharate. 8271. Apr. 1.

XVIII.—Application

Blair, Campbell, and McLean, Ltd., and Moeth. Dehydration of alcohol. 8630. Apr. 5.

XVIII.—Complete Specification Accepted

32,361 (1922). International Takamine Ferment Co. Yeast stimulant. (201,512.)

XIX.—Applications

Dorfmüller. Clarifying sewage water. 8541. Apr. 4.

Grard. Synthetic preparation of butter. 8445. Apr. 3.

Hobbs and Lane. Preserving and storing meat. 8108. Mar. 31.

Leach, Thornley and Maypole Margarine Works. Apparatus for manufacture of margarine etc. 8367. Apr. 2.

XIX.—Complete Specification Accepted

1920 (1924). Declercq. Water-purifying apparatus. (210,437.)

XX.—Application

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of complex metallic arsenobenzene compounds. 8632. Apr. 5. (Ger., 9.4.23.)

XXI.—Complete Specification Accepted

624 (1923). Shaw. Sulphide toning or intensifying of photographic images. (213,354.)

I.—Applications

Barron and Son, Ltd., and Garron. Impact grinder. 8996. Apr. 9.

Carrier. Refrigerating mediums etc. 9005, 9016. Apr. 9.

Freeman. Centrifugal separators. 8895. Apr. 8.

Gall, Scholield, Tinsley, and Tinsley and Co. Optical pyrometers. 8888. Apr. 8.

Lang, Lang and Son, and Salaman. Dehydrating compositions. 9035. Apr. 9.

Marks. (Liptak Fire Brick Arch Co.) Furnaces. 8749, 8750. Apr. 7.

Norbeck. Furnaces. 8983. Apr. 9.

Reddie. (Campbell). Open-hearth furnaces. 9052. Apr. 9.

Schnell. Heat-insulating materials for steam pipes. 9157. Apr. 10.
Schneany. Regenerative furnaces. 8877. Apr. 8.
Stafford. Drying system. 8850. Apr. 8.
Wreesmann. Desiccating liquid substances. 9314. Apr. 12

I.—Complete Specifications Accepted

1795 (1923). Deschamps. Facilitating physical or chemical reactions in masses of loose material. (192,089).
10,311 (1923). Robson. Apparatus for filtering liquids. (213,777).

II.—Applications

Algem. Norit Maatsch. and General Norit Co. Process of producing activated carbon. 8772. Apr. 7. (Ger., 26.5.22).
Algem. Norit Maatsch. and General Norit Co. Reactivating decolorising carbon. 8896, 8897. Apr. 8. (Ger., 26.5.22).
Deschamps. Method of stimulating combustion of fuels. 9152. Apr. 10. (Fr., 16.4.23).
Helps. Gas manufacture. 9217. Apr. 11.
Prescott and Worger. Fuel briquettes. 8883. Apr. 8.
Umpleby. Gas-generators. 8693. Apr. 7.

II.—Complete Specifications Accepted

29,780 (1922). Butler. Process of making liquid fuel. (213,628).
175 (1923). Internationale Bergin Compagnie voor Olie en Kolen-Chemie, and Hofsass. Purifying and hydrogenating heavy mineral oils, coal distillates, coal slimes, etc. (213,661).
17,269 (1923). Humphreys and Glasgow, Ltd. (Evans O. B.). Manufacture of water-glass. (213,818).

III.—Application

Potts. (Stinnes and Weindel.) Decomposing coal tar etc. into phenols and neutral oils. 8950. Apr. 9.

III.—Complete Specification Accepted

175 (1923). Internationale Bergin Compagnie voor Alie en Kolen-Chemie, and Hofsass. See II.

IV.—Applications

Imray. (Soc. of Chemical Industry in Basle.) Manufacture of green triphenylmethane-azo dyestuffs. 8808. Apr. 7.

IV.—Complete Specifications Accepted

20,046 (1923). Eberlein. Manufacture of silicates of the basic dyestuffs. (201,941.)

V.—Applications

Dieker. (Rubber Latex Research Corporation.) Paper. 8706. Apr. 7.
Dicker. Batted or felted materials. 8708. Apr. 7.
Hammy, and Know Mill Printing Co. Treatment of cellulosic fibres etc. 8963. Apr. 9.
Ioco Rubber and Waterproofing Co., Ltd. Manufacture of metallised waterproof fabrics etc. 9260. Apr. 11. (Fr., 20.10.23.)
Jackson, and Jackson, Ltd. Apparatus for hydrating fibrous pulp. 9107. Apr. 10.

V. Complete Specifications Accepted

30,136 (1922). Levy. Manufacture of cellulose acetate. (213,631.)
1949 (1923). Jackson. Paper and paper-making. (213,709.)
8967 (1923). Courtaulds, Ltd., Napper, and Diamond. Treatment of cellulose. (213,765.)
15,519 (1923). Brumby, Howard, Mercer, and Brumby and Clarke, Ltd. Manufacture of transparent paper. (213,810.)

VI.—Application

Farbenfabr. vorm. F. Bayer u. Co. Process for dyeing acetate silk. 8904. Apr. 8. (Ger., 14.4.23.)

VII.—Application

Metal Traders, Ltd. Production of chamber crystals. 8744. Apr. 7. (Ger., 7.4.23.)

VIII.—Application

British Refractories Research Assocn., Dale, and Mellor. Manufacture of clay-industry products. 8935. Apr. 8.

IX.—Applications

Child and Lutyens. Composition for roofing, road surfacing, etc. 9230. Apr. 11.
Davis. Manufacture of cement. 8903. Apr. 8.
Gaertner. Process of making cement etc. 9269. Apr. 11
Mackay. Bituminous emulsions. 8926. Apr. 8.
Ross. Treatment of concrete, brickwork, etc. 8695. Apr. 7.
Schnell. 9157. See I.
White. (Tehafo Technische Handels-u.-Forschungs-Ges.) Concrete. 8900. Apr. 8.

X.—Applications

Aarts. Oven for treating iron ores. 9192. Apr. 10.
Bown, and Bown. Composition for welding cast steel. 8999. Apr. 9.
Clark, Sumpter, and Vickers, Ltd. Heat treatment of steel tyres etc. 9335. Apr. 12.
Guise, and Scriven. Treatment of metal articles for prevention of tarnish. 9279. Apr. 11.
Marino. Process of recovering constituent metals of tin-plate etc. 9292. Apr. 12. (Belgium, 28.11.23.)
Reddie (Campbell). 9052. See I.
Wilson. Welding. 9070. Apr. 10.

X.—Complete Specifications Accepted

27,342 (1922). Haneiau. Recovery of gold, platinum, and other metals. (213,626.)
33,109. (1922). Harris. Separation of arsenic and tin in presence or absence of antimony. (213,639.)

XII. Complete Specification Accepted

1980, (1923). Lund. Production of alkali salts of higher fatty acids. (213,710.)

XIII.—Applications

Caspari. Manufacture of protective paints etc. 8793. Apr. 7.
Defries, and Sorbo Rubber-Sponge Products, Ltd. Manufacture of paints, varnishes, etc. 8892. Apr. 8.
Soc. of Chemical Industry in Basle. Manufacture of artificial resins. 8809. Apr. 7. (Switz., 9.4.23.)

XIV. Applications

Hammond. Coagulation of rubber latex. 8848. Apr. 8.
Wescott. Rubber emulsions. 8707. Apr. 7.

XIV. Complete Specifications Accepted

22,876, 8, and 9 (1923). Plantation Rubber Manufacturing Co., Ltd., and Dessau. Printing on rubber. (213,835-7.)

XV.—Application

Atkin, and McCandlish. Treatment of hides etc. 9073. Apr. 10.

XV.—Complete Specification Accepted

5625 (1923). Forster. Treatment of hides for the production of articles of leather. (213,740.)

XVII.—Application

Burunat. Treatment of bagasse. 8901. Apr. 8.

XIX.—Application

Squibb and Sons. Preventing vitiation of vitamine A 8699. Apr. 7. (U.S., 9.4.23.)

XX.—Applications

Lockemann. Manufacture of 1-phenyl-2.3-dimethyl-4-dimethyl amino-5-pyrazolone. 9163. Apr. 10. (Ger., 10.4.23.)
Sokal (Kalle and Co., Akt.-Ges). Process for producing perylenetetracarboxylic acid or its derivatives. 8895. Apr 7..

XX.—Complete Specifications Accepted

1980 (1923). Lund. *See* XII.

17,375 (1923). Chemische Fabrik Flora. Producing para-amino-benzoyl derivatives of 2-methyl-4-diethylaminopentanol-5 and 2-methyl-4-dimethylaminopentanol-5. (200,810.)

24,306 (1923). Farbwerke vorm. Meister, Lucius und Bruning. Manufacture of arsenobenzene derivatives. (204,721.)

XXI.—Complete Specification Accepted

31,721 (1923). Comp. d'Exploit. des Proc. de Photographie en Coleurs L. Dufay. Manufacture of photographic prints in colours. (208,564.)

FORTHCOMING EVENTS

Apr. 28. The Ceramic Society. Annual meeting in the Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Note on the Use Wood-wool as a Packing Material," by B. Olsen.

Apr. 29. Society of Chemical Industry, *South Wales Section*. Visit to the works of Messrs. Vivian and Sons, Ltd., Copper Works, Llandore, at 2.15 p.m.

May 2. Society of Chemical Industry, *Chemical Engineering Group*. Fifth annual general meeting, to be held in the Watt Room of the Engineers' Club, 39, Coventry Street, W. 1, at 6.30 p.m. An informal dinner (tickets 6s. 6d.) will be held after the meeting, followed by a social evening, including musical and other items.

May 2. Institute of Metals, *Swansea Local Section*. University College, Singleton Park, Swansea, at 7.15 p.m. Annual general meeting.

May 2. Society of Chemical Industry, *Manchester Section*, Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "Some Organic Sulphur Compounds" (in relation to the determination of total sulphur in petroleum), by J. Atkinson, M.Sc., and L. Guy Radcliffe, M.Sc.

May 5. Society of Engineers. Apartments of the Geological Society, Burlington House, W., at 5.30 p.m. "Some Factors of Sea-defence Work," by C. H. J. Clayton.

May 5. Institution of the Rubber Industry, *London Section*, Engineers' Club, Coventry Street, London, W., at 8 p.m. "The Rubber Industry—A Plea for Closer Working," by J. Fairbairn.

May 8. Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C. 2, at 6 p.m. Annual General Meeting.

May 8 and 9. Iron and Steel Institute, at the Institution of Civil Engineers, Great George Street, London, S.W. 1. Annual Meeting. Annual dinner at the Hotel Cecil, Strand, W.C. 2, on May 8, at 7.15 for 7.30 p.m.

May 21. Royal Microscopical Society, 20, Hanover Square, W. 1, at 7.30 p.m. "Brief Observations on the Mounting and Photomicrography of Radulæ," by Dr. E. W. Bowell, M.A.

May 28. Royal Microscopical Society, 20, Hanover Square, W. 1, at 7 p.m. *Industrial Applications Section*. (1) Lecture Demonstration 6. A résumé of the whole subject, "The Efficient Use and Manipulation of the Microscope," by J. E. Barnard. (2) "Use of the Microscope in the Examination of Paper," by Mr. Lester.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Australia :* Steel, (13520/E.D./E.C./2) ; (13521/E.D./E.C./2) ; *Belgium :* Manganese ore, acetone, sodium sulphate, (416) ; Artificial silk, (418) ; *Chile :* Steel, (9649/F.L./E.C./2) ; *Czechoslovakia :* Raw phosphates, (420) ; *Germany :* Silk, (421) ; *Greece :* Metals, hardware, (422) ; *Latvia :* Kerosene, (9085/F.R./C.C./2) ; Iron, (9103/F.R./E.C./2) (A) and (B).) ; *Netherlands :* Copper, phosphor bronze, iron cutlery and enamel ware, (432) ; *Portugal (Madeira) :* Metal, tinplate, (436) ; *Sweden :* Shellac, (438) ; Silk, (440) ; *Switzerland :* Steel, timplate, (442) ; Pig and cast iron (21235/F.W./E.C./2).

Notes from Italy

Orders and Notices, issued by the Italian Government, have of late been of particular interest to chemists. Thus, one Royal Decree (Dec., 18, 1923) establishes the "Consiglio Nazionale di Ricerche," affiliated to the International Research Council, and the "Unione Accademica Nazionale," affiliated to the International Academic Union. The National Research Council is composed of the presidents and general secretaries of the national committees, a delegate from the Accademia dei Lincei, one from the Ministry of Foreign Affairs, and one from the Ministry of Public Instruction. A State subvention of 175,000 lire is accorded for the work of the National Research Council, and 100,000 lire for that of the Academic Union.

Another Decree, dated December 31, lays down the list of professions the exercise of which requires the possession of a State certificate, awarded on examination. The use of the title of specialist in any of the professions named is permitted only to those possessing an appropriate diploma, and offenders will be excluded from the profession as well as subjected to other penalties. The professions listed included those of chemist, engineer and pharmacist, and each applicant is required to possess appropriate degrees (laurea) in his particular subject. In addition, special regulations control the admission of candidates to the teaching profession.

ROYAL MICROSCOPICAL SOCIETY

A meeting of the Industrial Applications Section of the Royal Microscopical Society was held at 20, Hanover Square, on March 26, 1924, with Dr. Stephen Miall in the chair.

Mr. G. O. Searle (Linen Industry Research Association) communicated a paper, entitled "Methods of Mass-Production in Sectioning Flax Stems." He said that in carrying out a genetic investigation of certain fibre characters of the flax plant it was found necessary to devise a method by which transverse sections of up to 3000 flax stems could be cut and mounted by one person within a limited available period of about four months each year. The method finally devised consists essentially of making kite tails of cotton, each with small pieces from forty stems; in this way 1000 stems could be dehydrated and embedded in celloidin at one time without mixing. After microtoming, the sections, six from each stem, three of which were later discarded, were placed in small silk ended tubes, and forty of these tubes were placed in a larger long glass tube, into which solutions could be poured as required; in this manner the sections were uniformly double stained and dehydrated ready for mounting. A careful record of time and materials was kept, and it was found that 2000 stems could be dealt with, and three sections from each stained and mounted at an expenditure in time amounting for one person to six hours per day for 84 days, and an expenditure of materials equalling 2½d. per stem, half of which was for slides and cover glasses.

Mr. Harold Wrighton, B.Met., also read a communication on "Microscopical Metallurgy."

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, MARCH 7, 1924 No. 10

EDITORIAL

THE short article in this week's issue on "Steam Generation at the Critical Temperature," recalled to us our student days. It seems a very long time ago since we struggled with Carnot's cycle and the formulæ of Gibbs and Helmholtz, and we confess that we have forgotten what little we then knew of thermodynamics and have no inclination to return to it. But we should enjoy sometime reading again the tracts of Andrews on the continuity of the gaseous and liquid states. Who Andrews was and what he looked like, we never knew; whether he was addicted to verse or worse; but we have a vague recollection of his researches and will refresh this. Did he not deal with mixed gases—or was it Cailletet? and find that carbonic acid could be liquefied at a higher temperature if mixed with air than if pure? Has anyone repeated these experiments? is there an easy explanation of the facts and are the matters of any practical value? Perhaps some reader can enlighten us on some of these points connected with critical temperatures. It is not surprising that one retains a curiosity about some parts of a science and some parts only. If the science is your business or avocation you are spurred by the thoughts of home and the tax-collector to know your subject. But the amateur must choose somewhat daintily, perusing only those topics which appeal to him and the books whence he may learn and clearly discern such truths as attract his inquisitive turn. Voltaire, whose advice to a journalist constitutes our only text-book in that art, said, "Les livres sont la peinture de la vie humaine, il en faut de solides, et on en doit permettre d'agréables." Somebody else, of like nature to our own, after speaking of the value of Greek as a school subject, said that a wise man on leaving school will throw away his Euclid but keep his Theocritus. We all make a selection for ourselves, usually preferring that which is the most interesting or the least fatiguing, even Jinny: Some parts of the Bible by heart she recited, and much in historical chapters delighted, but in points about faith she was something short-sighted.

* * *

The Cantor Lectures now being delivered by Mr. E. V. Evans at the Royal Society of Arts are of interest and importance, and Mr. Evans is introducing some novel features such as kinematograph films to show the changes which occur in some of the molecules, with which the gas manufacturer is dealing. The scientific examination of the distillation of coal at various temperatures and under various conditions has received much attention during the last twenty years, and Mr. Evans' own contribution to this subject is by no means inconsiderable. The products of coal distillation have received an amount of attention incredible except to those who have followed the subject closely and since the discovery of naphthalene and benzene a hundred years ago the gas manufacturers have made great advances in the output of intermediates. It is from one of these, H-acid, that the cure for sleeping sickness, Bayer 205, is derived, as we announced in last week's issue. But though the literature on coal products is extensive the actual knowledge we possess of the structure and properties of coal is comparatively scanty. This fossilised sunshine is steadily yielding to research and the fuel problem is at last being approached by men of insight and practical experience. When, as sometimes happens, we have occasion to light or re-light a fire in what is called a domestic hearth we wish someone, Mr. Evans for instance, would explain to us exactly what happens. The flame of the paper, sufficing to light the wood, the exact process of the burning of the wood and then the way in which a piece of coal begins to ignite; all these present problems which we should like to explain to a younger generation whose curiosity is insatiable, but we are ourselves not sure of the facts and they seem not readily accessible in *Evenings at Home* or the *Boys' Own Paper*; consequently, we shirk the subject. Some of our chemical friends have shown us that a lump of sugar cannot be ignited by a match unless the lump be "activated," if that is the right word, by the addition of some cigarette or other ash to a corner of the lump. At present this is merely a parlour trick, perhaps Mr. Evans can include this problem in his third Cantor Lecture. By the way, we owe him and our readers our apology for omitting in our previous issue a notice of his second lecture. We much regret the omission.

REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The advent of the Annual Reports of the Progress of Applied Chemistry is always awaited with a certain eagerness, even if one wishes only to see how far the review of the development of one's own particular subject coincides with one's own views, or to glean ideas from the trend of other departments of applied chemistry. Whatever may be the reasons—and there are many—for procuring the Reports, these are now indispensable, and the Society of Chemical Industry has done well in offering advantageous terms to those who, having one, wish for all, though they will be too late to procure the first volume.

Volume VIII, which will be issued in a few days, is again edited by Mr. T. F. Burton, B.Sc., editor of the Transactions and Abstracts. Plant and machinery are this year treated by Mr. J. H. West, who records the important events of the foundation of the Institution of Chemical Engineers and that of the Ramsay Memorial Chair of Chemical Engineering, and describes Dr. Hele-Shaw's "stream-line filter," and other developments in the domains of fine grinding, "heat pumps," heat transference, leaching and other chemical-engineering subjects. In the review of Fuel, Mr. E. C. Evans discusses the scientific, economic and social aspects of the fuel problem. Peat, lignite, oil shales and liquid fuel provide material for some interesting discussion, especial mention being made of hydrogenation, as in the Bergius process. Coal receives full attention under the heads of analysis, constitution and low-temperature carbonisation, and coke is discussed from a variety of standpoints, particular attention being paid to "combustibility." Messrs. F. M. Potter and D. Ivor James contribute a lengthy account of progress in the Gas Industry, and refer to an unusually large number of papers embodying the results of careful work directed towards obtaining a maximum of efficiency and a reduction of operating costs. Naturally, carbonisation is to the fore, but the accounts of benzol recovery, corrosion, the yield of ammonia, tar and its products will be found of much interest. Recent work on the origin of petroleum, the analysis, distillation and other treatments of crude oils, is described by Dr. S. J. M. Auld in the section on Mineral Oils, which also includes chapters on motor fuels, lubricants, and lubrication, wax, natural gas, asphalt and shale.

An interesting review of the dyestuff industry is given by Mr. J. Baddiley in "Colouring Matters and Dyes," in which he points out that the quality and range of British-made dyes is now satisfactory but that the industry still needs nursing. This section will be read most closely owing to recent events, but apart from the economic side, numerous points of a scientific and technical nature are deserving of close attention. Much steady progress is recorded by Dr. C. Dorée, who deals with Fibres, Textiles, Cellulose and Paper. Interesting work on the chemistry and structure of cotton is reviewed, and wool and flax receive attention, as well as other fibres, natural and artificial. The discussion of recent work on the constitution of cellulose is particularly full, and the chapters on cellulose compounds, lignin, wood pulp, and paper will be found to contain many interesting points. Mr. Fort, who writes on Bleaching, Dyeing, Printing and Finishing, complains that bad trade has hindered the development of inventions and improvements, but he nevertheless finds that there is plenty of attractive work to draw attention to, of particular importance being the development of the dyeing of cellulose acetate silk.

In Acids, Alkalis, Salts, etc., Mr. H. J. Bailey discusses the recovery in the heavy chemical industry, and its set-back owing to the trade depression. He gives a clear description of the Quinan and Schmiedel processes of sulphuric acid manufactures, and reviews the increasing use of electrolytic methods for producing soda and its consequence, the growing output of synthetic hydrochloric acid. The subjects treated in this section include, *inter alia*, hafnium (celtium), nitrogen fixation, ammonium compounds, various acids and salts. Mr. E. A. Coad-Pryor in the section on Glass, remarks on the improvement in the quality of scientific glassware and glass containers, an improvement due to the growing recognition of the value of technical control, and indicates the increasing importance that is being attached to the physical side of the subject. As in former years, this section shows the valuable work done by the Society of Glass Technology. Dr. G. N. White observes that the meagre results in the Ceramic Industries is due to the complexity of the materials used and the type of work involved. As usual a good deal of work on clays has been done, particularly in relation to colloidal phenomena and hydrogen-ion concentration, and attention is called to various improvements in kilns, and work on the crazing of glazes on semi-porcelain. Much recent work on refractories is noticed and, under building materials, the decay of building stone and the setting of cement are dealt with. Important work by Japanese investigators in this and the preceding section is noteworthy.

Prof. C. O. Bannister contributes the section on Iron and Steel, which treats of the manufacture of iron and steel, foundry practice, the properties of iron and steel, and metallography, concluding with a full discussion of the important problem of corrosion. Non-Ferrous Metals are again dealt with by Prof. C. A. Edwards and Mr. H. I. Coe, who cover recent advances in metallurgy, metallography, including accounts of the mass of work on aluminium alloys. The section on the Electrochemical and Electrometallurgical Industries, by Dr. J. N. Pring, contains a full account of progress in the construction of electric furnaces, and in their use, such as for the manufacture of calcium carbide, electric steel, ferro-alloys and non-ferrous alloys.

Under Oils, Fats and Waxes, Mr. R. G. Pelly outlines the state of the trade in and technology of these products, and discusses drying oils, marine animal fats, solid fats, hardened oils, soap, fatty acids, and waxes. Dr. R. S. Morrell comments upon the steady increase of literature relating to Paints, Pigments, Varnishes and Resins, and provides a very full discussion of that relating to drying oils, resins, both natural and synthetic, and varnishes. Under pigments and paints, points such as the preparation of chrome pigments, the use of lead in

paint, plastic flow and other subjects receive attention. Mr. B. D. W. Luff contributes some interesting material in the section on India-rubber, special reference being made to the growing use of rubber latex. Problems of the chemical and physical properties and constitution of rubber are reviewed, other subjects in this section being vulcanisation, compounding ingredients, accelerators, ageing, testing and analysis. The contribution on Leather and Glue is due to Mr. D. Woodroffe, who deals with curing and salting, liming, bating, tanning and analysis, the " most interesting work during the year " having been done in connexion with the last-named subject. There is also a short account of work on glue and gelatin.

Mr. H. J. Page opens his account of " Soils and Fertilisers " by considering the nitrogenous fertiliser industry, showing the increasing use of synthetic products, and mentioning the newer ones. After discussing the relative efficiency of various nitrogenous fertilisers, space is devoted to phosphatic and potassic fertilisers, and to various materials for soil treatment. The report on " Soil " is confined mainly to work on methods of examination. " Sugars, Starches and Gums " are reported on by Mr. R. F. Lyle under the heads of the cane-sugar industry, the beet-sugar industry and the analysis of sugar products. Mr. Lyle finds there is not much of particular interest to report in regard to starches and gums, though reference is made to Prof. Ling's work on the determination of starch.

Mr. H. Lloyd Hind, in his account of the Fermentation Industries, notices the centenary of Pasteur, and shows how the conception of hydrogen ions is linking up isolated facts in fermentation and providing explanations for processes that were formerly empirical. Starch is dealt with at length in this report, as are enzymes, yeast and fermentation and cellulose fermentation, and an interesting description of the research scheme of the Institute of Brewing is given. In the report on Foods, Dr. Monier-Williams records advances in our knowledge of vitamins, milk and dairy products, fruit juices, and discusses the use of food preservatives, and food poisoning, and in Sanitation and Water Purification, Mr. J. H. Johnston chiefly reviews work on the theory of purification, the disposal of sewage, water supply, and disinfectants. Dr. H. King has much of interest to record in his reports on Fine Chemicals, Medicinal Substances and Essential Oils, *e.g.*, work on the pituitary hormones, on insulin, synthetic thymol, anaesthetics and hypnotics, organo-arsenic and antimony compounds. Bayer 205 and other antiseptics. Dr. John Weir contributes the section on Explosives, and remarks that there was no outstanding advance in the manufacture or application of explosives during the past year, although interesting activities were shown in certain directions.

In the course of a short notice, it is impossible to treat such a large subject in any way adequately, but it is hoped that enough has been said to show the wide scope and interest of the Reports of the Progress of Applied Chemistry, and to indicate their value to all who are in any way connected with or interested in chemistry and chemical industry.

SCIENCE AND SCIENTISTS UNDER NAPOLEON I.

By A. R. PEARSON, M.Sc., LL.B.

Fauvelet de Bourrienne, who was Bonaparte's private secretary from 1797 to 1802, referring to the fact that the class of sciences had been given precedence over that of literature in the *Institut National*, says in his Memoirs; " Considering the state of literature and science at that period, the First Consul did not make a wrong estimate of their importance. . . . Although the literature of France could boast many men of great talent, . . . yet they could not be compared with Lagrange, Laplace, Monge, Fourcroy, Berthollet and Cuvier, whose work has so prodigiously extended the bounds of human knowledge." France, during the Napoleonic period, was indeed extremely rich in men whose names are writ large in the history of science; Vauquelin, Proust, Guyton de Morveau, Gay-Lussac, Coulomb, Haüy, Biot, Arago, Lamarck, de Candolle may be added to Bourrienne's list. The state of literary depression, which prevailed throughout the Consulate and Empire, was partly due to the attitude of Napoleon himself. His practical mind was naturally attracted by science; but literature had not much appeal to him, and in his later years he disliked and distrusted literary men. They were theorists, phrasemongers. " These people," he said, " are good for nothing under any government. I give them rewards because it is my duty as Chief of State; they occupy and amuse idle minds. But I will make Lagrange a senator; there is a brain."

The period of the French Revolution was a time of revolution also in physical science. Speculation and the construction of " systems " were giving place to quantitative experiment with balance, burette and calorimeter. The overthrow of the phlogiston hypothesis by the work of Lavoisier, Laplace's investigations in celestial mechanics, and the discovery of galvanism, had not only stimulated the enthusiasm of the initiated, but had aroused a more general interest in science. This revivification or renascence was nowhere more evident than in France. The tragic fate of Lavoisier and Bailly during the Terror was quite unconnected with their status as scientific men. It was part of the result of a transient outburst of political fanaticism, and must not be construed as representing a general hostility towards science. The famous dictum of a member of the revolutionary tribunal, that the Republic had no need of savants, was meant rather to silence a petitioner than to lay down a principle of Republican government. The Jacobins made much use of the services of scientific men in the national defence; and some of the latter, who would have been condemned on political grounds, were saved on account of their possible utility to the State. It was on this plea that Guyton de Morveau saved the great mathematician Lagrange from being exiled on account of his foreign birth.

In the social reaction after the fall of Robespierre, it was fashionable to take an enlightened interest in science and literature. Thus Bonaparte writes from Paris to his brother Joseph in July, 1795:

"Luxury, pleasure, and the arts are reviving here in a wonderful manner. . . . Libraries are formed, and we have lectures on history, chemistry, botany, astronomy. . . ." In the same year, the Convention founded the *Ecole Polytechnique* as a school of pure and applied science, to rank beside the colleges hitherto exclusively devoted to law, literature and medicine. (The last of these three subjects was rather an art than a science in those days.)

The old *Académie française* and the *Académie des Sciences* having gone the way of other royal institutions in 1793, the Convention created in 1795 a National Institute, composed of men distinguished in various branches of learning. The Institute was originally divided into three classes, devoted respectively to science mathematical and physical, to science moral and political, and to literature and the fine arts. It was reorganised in 1803 under the First Consul's direction in four classes, namely :—

(1) Physical and mathematical science.
(2) French language and literature.
(3) Ancient literature.
(4) Fine arts.

It was characteristic of Bonaparte to suppress the class of moral and political science. He would not encourage discussion, criticism and possible ridicule of his government by the *idéologues* whom he so despised.

Bonaparte had himself been elected a member of the Institute in the classes of science and arts at the end of 1797, and he acknowledged his election in the following letter, which displays a clear perception of the value of research and the contribution which science can make to national prosperity :—

"CITIZEN PRESIDENT,—I am honoured by the suffrage of the distinguished men who compose the Institute. I feel that before being their equal I shall long be their pupil. If I can convey in any more expressive manner my esteem for you, I shall be glad to do so.

True conquests, the only ones which leave no regrets, are those which are gained over ignorance. The most honourable, as well as the most useful, occupation for nations, is to assist in extending human knowledge. The true strength of the French Republic should henceforth consist in not allowing a single new idea to exist without adopting it as part of its own property. BONAPARTE."

Acting on these opinions, he included in the Egyptian expedition of 1798 a band of scientific men—chemists, physicists, biologists—who were to assist in developing the resources of the country. The idea of adding a corps of savants to a military expedition was a novel one, and the party was an object of some suspicion to the rank and file during the hot and thirsty march up the Nile to Cairo. The men, having noticed that all vestiges of antiquity were carefully examined, vented their discontent in invectives against the savants ; who, they said, had started the idea of the expedition in order to carry out antiquarian researches. And when, on any alarm, they were ordered to open the square and give the learned party, mounted on asses, with their instruments and baggage, safe footing within, they used to receive it with military jests : "Room for the asses. Stand back, here come the savants and the *demi-savants* !"

One of the General's first acts after subduing the country was to form an Institute of Science and Arts at Cairo, modelled on that of Paris. It consisted of the savants, staff-officers and others interested in learning. The mathematician Monge was president, Bonaparte was vice-president, and the secretary was Fourier, afterwards famous for his work on the mathematical theory of heat-conduction. The papers read before the Institute show a great diversity of topics. Thus we find contributions by Berthollet on the occurrence of salammoniac and on the production of indigo in Egypt ; Fourier describes "a general method of extracting the roots of equations" ; and one of the staff-officers gives an account of a bust of Isis found near the Nile.

Bonaparte's intention was to plant a permanent colony in Egypt, and with this end in view he proposed a number of important practical matters for consideration by the Institute. Scarcity of fuel is a perennial problem in that country, and it is not surprising to find, among the first of these questions : What means are there of economising fuel in the army ovens ? Water supply naturally claimed attention ; the relative advantages of windmills and water-mills were discussed, and Berthollet and his assistants carried out complete analyses of the dissolved solids of the Nile water. The resources of the country for manufacturing gunpowder, and the possibility of finding a substitute for hops in beer, were other problems dealt with.

Of all his scientific advisers at this time, Bonaparte seems to have placed most confidence in Berthollet. Their connexion had begun in 1796, when Berthollet and Monge were sent to follow the victorious general in Italy, and to select the works of art which were to be sent from the captured towns to Paris. Berthollet was one of the small party which accompanied the General's sudden return from Egypt in 1799.

During the Revolutionary wars against the First Coalition, Berthollet had been employed by the Committee of Public Safety to superintend the manufacture of nitre, and this work seems to have given rise to his first ideas on chemical statics and affinity. He observed that the earthy matter from which the nitre was extracted always retained a portion of it, in spite of the fact that the aqueous solution was far from saturated ; and he attributed this to an equilibrium between the "affinity" of the nitre for the earthy matter and its tendency to pass into solution. The phenomenon is now called adsorption, and it is well known that the proportion of a substance adsorbed can vary continuously. Hence doubts arose in Berthollet's mind as to the validity of the Law of Constant Proportions. These ideas were further developed during his stay in Egypt by an investigation of the natron lakes in the desert south-west of the Delta. The action of brine on the calcareous rock has caused deposits of carbonate of soda, and these deposits were the subject of Berthollet's first paper on chemical affinity and mass action, read before the Cairo Institute. The complete theory was published in the famous *Essai de Statique chimique* in 1803.

Berthollet used to give frequent experimental demonstrations before the Institute in his laboratory, which was installed in the palace of one of the Beys. The Mamelukes had a great respect for prophets and magicians, and Bonaparte, with his usual readiness to draw advantage from circumstances, determined to oppose sorcerer to sorcerer. He therefore invited the principal sheiks to one of these demonstrations, expecting to enjoy their astonishment and to impress them with awe of the French conquerors. "But," says Bourrienne, "all the wonders of the transformations of liquids, electrical commotions, and galvanism occasioned in them no surprise. They watched our clever chemist with imperturbable calm." And when the demonstration was concluded, the Sheik, El Bekri, informed the interpreter that it was very fine; "but ask him," he said, "if he can make me be in Morocco and here at the same time." Berthollet shrugged his shoulders. "Then in that case," answered the Sheik, "he is but half a magician." The standard of professional competence for magicians has always been high in Egypt; he needs both courage and skill who will claim succession to Moses and Hermes Trismegistos, or maintain the traditions of Memphis and Alexandria.

Berthollet's services ultimately gained him the Cross of the Legion of Honour, and he became a Senator and Count under the Empire.

Bonaparte became First Consul towards the end of 1799, and in organising his administration he chose Laplace as Minister of the Interior. Laplace's studies in mathematical astronomy, his nebular hypothesis, his theory of capillarity and his proof that sound-waves are propagated under adiabatic conditions, form a sufficiently imposing monument in the temple of science: but as a minister he was a failure. Bourrienne says of him: "As to Laplace, Bonaparte always held a high opinion of his talents. His appointment to the Ministry of the Interior was a compliment paid to science, but it was not long before the First Consul repented of his choice. Laplace, so well adapted for science, displayed the most inconceivable mediocrity in administration; as if his mind, constructed to grasp the system of the universe and to interpret the laws of Newton and Kepler, could not descend to the level of matters of detail nor apply itself to the duties of the department with which he was entrusted." Laplace was indeed wasted in the ephemeral details of administration. Of his ministerial colleagues, Carnot set a high example of integrity in public life; Talleyrand has left us a few epigrams and a reputation for political agility; while Cambacérès was famed for the excellence of his dinners. But what permanent fruits have their labours given to posterity? *Tenues recesserunt consumti in ventos.* Laplace has rendered humanity a more enduring service, and can say, with Horace, *Monumentum feci aere perennius.*

Laplace was superseded after a ministry of six weeks, and nominated to the Senate. He and the First Consul, each the most eminent living man in his *métier*, had a cordial regard for each other. The statesman gave the scientist the Cross of Honour, and the scientist dedicated his *Mécanique céleste* to the statesman.

After a short period under Lucien Bonaparte, the Ministry of the Interior was again offered to a man of science, Jean Antoine Chaptal, Comte de Chanteloup.

Chaptal was primarily an industrial chemist. Although his name is still to be found in chemical textbooks, it is not associated with any fundamental discoveries such as those of his contemporaries, Berthollet, Gay-Lussac and Vauquelin. The value of his work lay in his applications of chemistry to agriculture and manufactures. Already in 1781, when professor of chemistry at the College of Montpellier, he had started a factory where he made mineral acids, alum, sal-ammoniac, white lead, copperas and other chemical products. He devised improved processes for the extraction and application of the dye in madder root, and was the author of several works on applied chemistry (*Teinture du coton*, 1807; *Chimie appliquée aux arts*, 1807; *L'industrie française*, 1816). During the Terror, on the repeated invitation of the Committee of Public Safety, seconded by the entreaties of his friend, Berthollet, Chaptal devoted himself to organising the great powder factory at Grenelle. This circumstance saved him from sharing the fate of Lavoisier, for he had been imprisoned once as a leader of the southern Girondists, and would certainly have been brought before Fouquier-Tinville as a political "suspect" had not his services been necessary to the Jacobins.

Chaptal became a member of the Institute in 1799, and was called to the Council of State in the following year. Here he came in contact with the First Consul, and in November, 1800, succeeded Lucien as Minister of the Interior. He was an active and successful administrator. It was he who was charged with the reorganisation of the Institute in 1803, and with the formation of the Society for the Encouragement of National Industry. Many useful reforms and projects in education, public works, and the improvement of agriculture and manufactures were carried out under his ministry.

As Napoleon developed his system, he no longer wanted men of independent mind. He wished everything to be under his own immediate cognisance. As Chaptal puts it*: "He needed valets, not counsellors. His ministers were merely head clerks." Chaptal was by no means this kind of man, and in August, 1804, two months after Napoleon became Emperor, he tendered his resignation, alleging the desire to resume his scientific work. Napoleon accepted the resignation, but nominated him to the Senate, where his scientific knowledge and experience continued to be of great use. Méneval, the Emperor's *Secrétaire de Portefeuille*, says in his Memoirs: "I have heard Napoleon complain that this minister did not seek opportunities to talk to him . . . and did not inform him often enough of the business of his department. Perhaps the Emperor was yielding to certain prejudices inspired by the recollection of his unsuccessful experiment in entrusting the same ministry to Laplace . . . and he thought it was a bad thing for savants to be distracted from their studies, and that they were not able to devote themselves entirely to the multifarious details of administration. . . . How-

* *Mes Souvenirs sur Napoléon.* Published by Chaptal's grandson, Paris, 1893.

ever, this was not so in the case of M. Chaptal, who was a practical savant. For the rest, he continued to be treated with great regard by Napoleon, who constantly gave this distinguished scientist the proofs of appreciation of his talents."

Chaptal rejoined the Emperor during the Hundred Days, being made director-general of agriculture, commerce and industry. His declining years were spent in agricultural pursuits at Chanteloup, where he enjoyed the society of his friends Laplace, Berthollet and Monge.

After Trafalgar, it became of the first importance to make France as nearly as possible independent of overseas products. A Council of Commerce and Manufactures, of which Chaptal was a member, was formed to advise on this problem. Strenuous efforts were made to find substitutes for indigo, cotton, cane-sugar, coffee, quinine and the like, and large rewards were offered to inventors. Chevreul, then assistant to Vauquelin at the Museum of Natural History, carried out one of the earliest researches of his long career on the colouring-matter of the woad plant (*Isatis tinctoria*), with a view to restoring it to the position in the dyeing industry from which Indian indigo had ousted it.

Coffee, so extensively used in France, was very difficult to replace. *Tisanes* of various herbs were an alternative rather than a substitute. The annual report of the Institute in 1814 mentions that an infusion of the roasted seeds of the yellow flag (*Iris pseudacorus*) is recommended, and is said to possess febrifuge properties which make it a possible substitute for quinine. Other roasted seeds and roots had been tried, but the report finally admits that "the drinks so obtained resemble coffee only in their dark colour and bitter taste."

The scarcity of sugar was the most keenly felt of all privations. Proust, the famous defender of the Law of Constant Proportions against the attacks of Berthollet, had discovered grape-sugar while working in Madrid in 1799. As the overseas markets for wines were cut off, an alternative use for the grapes was welcome; and a member of the Institute named Parmentier published in 1811 directions for purifying grape-juice and preparing a sweet syrup from it. Proust received the Cross of Honour and a considerable sum of money from the Emperor. The reward was clearly well deserved, but public opinion at that time was unaccustomed to seeing honours conferred for any but military and political services, and the learned pharmacist seems to have incurred some ridicule in the press:

"Pour avoir composé
De sirop de raisin trois ou quatre topettes,
Mon vieil apothicaire est mis dans les gazettes!"

The existence of sugar in beetroot had long been known, and the first beet-sugar factory had been started in Silesia under the patronage of the King of Prussia in 1799. The Institute therefore appointed a committee to inquire into the production of sugar from beet and other vegetables. This committee, which included Chaptal, Fourcroy, Guyton de Morveau and Vauquelin, published in 1811 "Instructions pour extraire le sucre de betterave." The first successful French manufacturer was Baron Delessert, one of the leading industrialists of the day, and a member of the Council of Commerce On hearing of the success of Delessert's process the Emperor at once rode off with Chaptal to the factory at Passy. Having examined everything, he took off his own Cross of Honour and fastened it on Delessert's breast. Under the drastic protection of the Continental System the industry grew apace; but at the Restoration, the market being suddenly flooded with the West Indian product, many factories were closed.

Napoleon recalled with pride at St. Helena that he had established a system of technical education to supply the needs of industry. From his technical colleges, he said, "hundreds of able chemists went to the different manufactories. In each of them I caused a person well-skilled in chemistry to reside. In consequence, everything proceeded upon certain and established principles, and they had a reason to give for every part of their operations, instead of the old vague and uncertain mode."† The provision of teachers for the technical colleges was the function of the Imperial University, which was created in 1806, and placed under the control of a council of eminent savants. These educational measures were drawn up and piloted through the *Corps Législatif* by the Comte de Fourcroy, director of public education under the Ministry of the Interior. Fourcroy, like Chaptal, was not only a chemist but an efficient minister. Indeed, his work in organising the educational system, successively under the Convention, the Consulate and the Empire, is a better title to fame than his chemical work; for, although he turned out a great bulk of research, chiefly in collaboration with his pupil and friend Vauquelin, much of it was superficial and hasty. He was an excellent teacher, however, and his lectures on chemistry at the Jardin des Plantes drew large audiences.

Professor Volta, of the University of Pavia, invented his electric pile in the year 1800, and the First Consul invited him to come to Paris and demonstrate some experiments before a committee of the Institute. In spite of his load of administrative work and the peace negotiations with England, Napoleon insisted on being present at the session when Biot presented the committee's report, and on his proposal a gold medal and a sum of money were awarded to the inventor. So struck was he with the importance of Volta's work, that he created an annual prize of 3000fr. for the encouragement of studies in the science of electricity and galvanism. This prize was awarded to Davy in 1808 for his work on electrolysis of solutions, and was divided in 1809 between Gay-Lussac and Thénard.

Napoleon was similarly interested by Chladni's observation that sand spread on a metal plate forms regular figures when the plate is set in vibration. After seeing the experiment he desired the Institute to offer a prize, open to all the scientists of Europe, for a mathematical theory of the phenomenon. There appears to be no record that this prize was ever awarded.

† Napoleon in Exile. A Voice from St Helena. B. E. O'Meara, 1822.

In the year 1802 the Institute was charged to present to the Council of State a report on the progress and condition of science, literature and art since 1789. Owing to the war, the report was not presented to the Emperor until 1808. The deputation of the class of science was admitted first into the Imperial presence, and after an introductory speech by the president Bougainville, the secretaries Delambre and Cuvier read the reports of their respective sections. These reports give a striking picture of the foundations of modern science in the making.

Delambre, for the mathematical section, dealt with the measurement of the arc of longitude on which the metric system is based. He was himself responsible for the northern half, from Dunkirk to Rodez, and his colleague Méchain for the rest as far as Montjouy, near Barcelona; a further extension to the Balearic Isles was carried out by Biot and Arago.

Cuvier then gave an account of the advances in physical science, of which may be briefly mentioned: Lavoisier's theory of combustion; the work of Dalton and Gay-Lussac on thermal expansion; Berthollet's theory of affinity and mass action; Haüy's proof of the uniformity of corresponding angles in crystals; the discoveries of Galvani and Volta, and Davy's applications of the voltaic pile; Jenner's discovery of vaccination; the application of chlorine to destroy "germs of contagion" by de Morveau; the analytical work of Fourcroy and Vauquelin on vital products.

The Emperor replied briefly to the deputation, assuring the Institute of his support. "The well-being of my peoples and the glory of my throne," said he, "are alike interested in the progress of science."

Méneval, who was present on this occasion, says that "the Emperor remained struck by the eloquence and clearness of ideas of M. Cuvier, who spoke fluently for several hours. Suspending the rule which he had imposed on himself, of not distracting learned men from their studies, Napoleon made M. Cuvier Master of Requests in the Council of State, and gave him a high appointment in the Imperial University."

Cuvier, whose first paper on palaeontology had appeared at the opening of the Institute in April, 1796, was in fact made a Councillor of the University, and later Councillor of State.

It has been mentioned above that the Emperor became increasingly reluctant to hear any opinion but his own on administrative matters. His contempt for men in general, the habit of despotic power, and his confidence in his star, made it useless to offer advice directly, however good the arguments by which it was supported. But he was always more receptive towards scientific men. He welcomed their conversation; he was always alive to the possibilities of their work, and ready to encourage research. The following anecdote, recounted by Chaptal himself, shows the circumspection necessary in approaching him, and at the same time proves his real regard for scientific work. The celebrated Prussian scientist and traveller, Alexander von Humboldt, had settled in Paris in 1808, and the Emperor suspected him of being a spy. "One day he ordered Savary, Minister of Police, to have him removed from Paris within 24 hours. The order was communicated to Humboldt, who at once came to me and asked me to speak to the Emperor on his behalf. I went to the soirée at the Tuileries; as usual, the Emperor drew me aside to converse.

"What is there now in the scientific world?" he asked.

"Nothing," I answered, "and were not M. Humboldt publishing his travels in Central America, we should be in a state of complete stagnation."

"These works are very important, very important?"

"They could not be more so. M. Humboldt is master of all the sciences, and when he travels, it is as if all the Academy of Science went too. It is astonishing that he has been able to collect in three years all the material on which he is working in Paris. Moreover he has adopted our country; he publishes his work in our language, he employs our engravers, our artists, our printers."

"Does he not also engage in politics?"

"His reputation brings him into contact with many foreigners, who come to see him; but I have never known him concern himself with anything but science."

"You think he is necessary to France?"

"There would be general regret if he chanced to leave us."

Napoleon called Savary, and ordered him not to put into execution the order which he had received that morning. . . . "If I had appeared to be aware of the step he had taken, and had spoken to him on the subject, I should have obtained nothing."

Napoleon's predilection for science was not entirely a white passion. It was made subservient to aggressive political designs. But whatever his ultimate motives were, we must ascribe to him this merit, that he was the first great monarch to give science its true place as a factor in human life. Others before him had indeed patronised science. The Academy of Sciences under Louis XIV. and XV. was an appendage of the Court, and the Court took an interest in the little tricks and wonders of science, just as it did in Madame du Barry's Indian dwarf or a new ballet. Frederick the Great liked to surround himself with learned men such as Voltaire and Lagrange, not so much because their knowledge was of value to the State, as because they gave an intellectual lustre to his Court. British monarchs would sign charters allowing a Society or an Institution to call itself Royal; but it is to be feared that their interest evaporated with the ink.

These rulers cannot, of course, be blamed for not seeing beyond their generations. They lived for the most part when physical science was as yet in its childhood. But Napoleon came at a time when it had begun rapidly to prove itself, and was prepared to play a fundamental part in civilisation and progress. He encouraged it to do so. His Legion of Honour was open to scientific, as well as military and political, achievements. His keen and enlightened interest in the advancement of science and his respect for scientific men are in refreshing contrast to the ruthless combativeness and self-will of the rest of his career: and under his rule science enjoyed a prestige which it had not known before.

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL

In the first of a series of Cantor Lectures delivered at the Royal Society of Arts on February 25, Mr. E. V. Evans considered the question of coal conservation from the viewpoint of a chemist in the gas industry. After indicating the particular conception of efficiency which the gas manufacturer may acquire from a study of methods adopted in the chemical industry, he demonstrated that carbonisation as practised in the gas industry is not the wasteful process which the pure chemist has often believed it to be. One ton of coal containing 300 therms will yield about 72 therms of gas of 560 B.Th.U. per cb. ft., 17 therms of tar, and 199 therms of coke. The process loss will be 12 therms. Under conditions of low-temperature carbonisation the coal will yield about 35 therms of gas of 1090 B.Th.U. per cb. ft., 26 therms of tar, and 223 therms of coke; under these conditions the process loss will be 16 therms.

Low-temperature coke contains about 9·3 per cent. of volatile matter, and this represents about 29 therms of the potential volatile matter of the original coal which is subsequently burned in the household fire as a gas of low calorific value. It would appear that, if the process of low-temperature carbonisation is to be as remunerative as that of high temperature, the consumer of the solid fuel must be prepared to pay for practically the whole of the potential volatile therms at their true gas price. If these potential volatile therms be added to those actually obtained in low-temperature carbonisation the result is not materially different from that obtained in high-temperature practice. Thus the low-temperature process is not superior from the point of view of efficiency; it is simply a different distribution of the thermal energy of the original coal, and may be considered as a high temperature process arrested.

The secret of preventing wastage of gaseous therms and of conserving the energy of the original coal lies firstly in the possession of a well-designed retort house maintained in the highest possible state of efficiency and repair. Improvements which may be obtained as a result of laboratory investigation are of slight importance compared with the wastage that may occur owing to imperfect working conditions on a large scale. The results of working under known imperfect conditions have been examined in some detail in an experimental plant.

Particulars were first obtained relative to the volume, calorific value, and analysis of the gas evolved from hour to hour when a typical Durham coal was carbonised under standard conditions. One of the outstanding observations was the large volume of gas of very high calorific value evolved during the first few minutes after charging the coal into the retort and this led to the application of a higher vacuum during the early stage of the carbonising period for the purpose of preventing decomposition of the unstable hydrocarbons evolved during this period. An initial vacuum of 18 in. water gauge was gradually reduced until a normal vacuum was reached at the end of the first hour. Under these conditions a larger volume of gas of lower calorific value was made, but there was no apparent increase in the yield of gaseous therms.

In other experiments the normal vacuum of $\frac{1}{10}$ in. was reduced to level gauge for 10 minutes during each hour in order to reproduce the conditions under which a retort is worked in actual practice when a proportion of the retorts connected to a common retort-house governor is charged with fresh coal each hour. There was a definite indent in the volume curve when the vacuum was reduced and immediately afterwards the calorific value of the gas rose appreciably. Again the thermal yield of gas was not materially affected.

The results obtained when carbonising coal in a retort in the crown of which there was a hole $\frac{1}{2}$ in. in diameter were, however, fundamentally different. With a uniform vacuum of $\frac{1}{10}$ in. throughout there was evidence that the rich gases were being lost through the hole during the early stages of the carbonising period. During the later stages there was a more rapid evolution of gas due to the influence of the furnace gases pulled into the retort. The calorific value of the gas was reduced materially, but it was noteworthy that the manufacture of gas was prolonged over a longer period owing to the manufacture of producer gas. In this case the thermal yield of gas was slightly increased, but it was very difficult to determine what was the yield of true coal gas owing to the inclusion of the producer gas reaction. It was estimated from the gas analyses that about 2 therms of coal gas (per ton of coal) had been replaced by producer gas therms. Superior results might be obtained by continuing the process and increasing the quantity of producer gas formed. Were it desired, however, to mix producer gas with coal gas for the purpose of dilution it would be more economical to manufacture this gas in a producer and to add it under control.

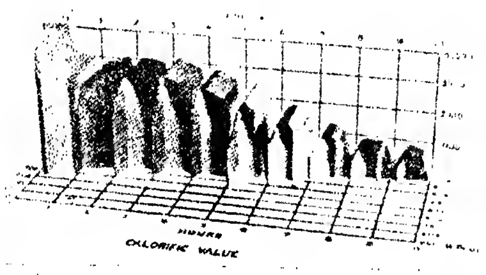

Fig. 1

The admission of air to the retort at a point corresponding to that at which the furnace gases were added resulted in the destruction of about 5 therms of true coal gas as a result of combustion. This loss was partly counterbalanced by the formation of producer gas to the extent of about 2 therms.

The admission of air through the door of the retort resulted again in the loss of rich gas by leakage during the early stages of carbonisation and in

the production of increased volumes of low grade gas during the later stages. In this case there was evidence that hydrogen had been burnt in the ascension pipe of the retort; in was noteworthy that the oxygen content of the gas was not increased.

A feature of the lecture was the number of models exhibited to illustrate the results obtained. A "thermal model" is illustrated in Fig. 1. The height represents the rate at which gas is evolved, the width, calorific value, and the length, time. Thus the volume representes the yield of gas in therms. The example illustrated shows the effect

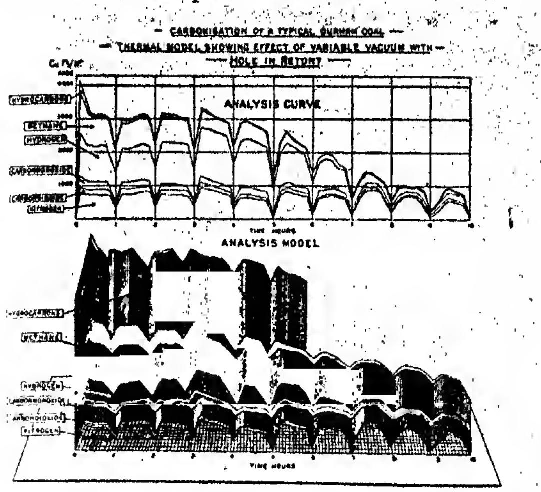

Fig. 2

of reducing the normal vacuum to level gauge each hour when there was a hole in the retort. The marked effect upon the volume and calorific value of the gas is realised at once by an inspection of this model. The volumes of the several constituents of the gas are shown in the curves reproduced in Fig. 2. In the analysis model the plan is a reproduction of the analysis curves and the height represents calorific value. Thus by dissection of the model the contribution of each constituent of the gas to the therm yield at any stage of the carbonisation is clearly demonstrated.

STEAM GENERATION AT THE CRITICAL TEMPERATURE

THE BENSON 3200 lb. PRESSURE BOILER

(From a Correspondent)

The Benson 3200 lb. pressure steam generator or coil "boiler," the invention of Mr. M. Benson, of the Benson Engineering Co., Ltd., 109, Kingsway, London, W.C. 2, which, it is understood, has now been put into operation with great success at Rugby, possesses extraordinary interest for the chemist and the chemical engineer. In the first place it means that power can be generated from coal by means of steam in large power stations at an overall efficiency of something like 28–30 per cent., even when usi the principle of condensing, as compared with, sa 17–18 per cent. for the most modern superpow station at 350 lb. pressure and 700° F. superhea This is, of course, a complete revolution in stea practice, and in fact, enables an efficiency to l obtained from raw coal almost equal to the Dies engine using expensive oil. Secondly, for the fir time we have a successful large-scale production steam at the actual critical temperature, that i about 706° F. (375° C.), equivalent to 3200 l pressure. The most familiar example to the chemi of critical temperatures of liquids is the use of carb dioxide in a thick glass tube, and it may be remen bered that this phenomenon was first observed long ago as 1822–1823 by Cagniard de la Tour, ar much work on the subject was also carried out l Faraday (*Philosophical Transactions*, 1823 and 1845 If liquid carbon dioxide contained in a glass tube slowly heated it expands and then at about th critical temperature (in this case 88·7° F.), th definite meniscus of the liquid begins to get indistin and suddenly vanishes, the whole of the liquid havir been converted into a gas at the same volume. Th exact difference between a liquid and a gas at th same volume is not known and is presumably som thing to do with molecular complexity.

In the "Benson" generator water is converte in the same way into steam at the critical temperatu of 706° F., that is, the whole mass of the water in th coils is bodily changed into steam at the same volun without the absorption of any latent heat, since th volume remains the same, about three times th original water at 60° F. It will be obvious that no latent heat is absorbed, and this figure, of cours diminishes in proportion to the rise in pressure can be seen on consulting the steam tables, there no ebullition or "boiling," that is, the sudde conversion of small particles of water into compar tively large bubbles of steam, the energy require for this increase in volume constituting the late (lost) heat. It is on these highly ingenious lin that the essential trouble of the small-bore co steam-generator has been overcome, the fact th because of the absorption of latent heat and cons quent ebullition the water will not stop in conta with the sides of the tube, and the generation steam is spasmodic and apt to be explosive. Th generation of steam at the critical temperature ha of course, completely eliminated this difficulty that narrow-bore steel coils can be used which w withstand almost any pressure; in fact, we a informed that the present installation has been teste hydraulically to 6400 lb. pressure.

The actual installation at Rugby, which is only o of a number of different arrangements possibl consists of generator coils of $\frac{3}{4}$ in. steel tube, $\frac{1}{4}$ i thick, placed to a height of 8 ft. 0 in. round an inn vertical cylinder of firebrick. This is surrounded b an outer casing of lighter refractories and a supe heater, consisting of similar coils is placed on the to the whole installation having overall dimensions 17 ft. 0 in. and 7 ft. 0 in. wide. Distilled water passed in continuously at the bottom of the coil b means of a motor-driven hydraulic force pum

working at 3200 lb. pressure, the evaporation on the trials being about 8000 lb. per hour, although 10,000 lb. is the normal figure and is easily obtained. The installation is heated from the bottom by means of an oil blast flame with heated air, simple for convenience in an experimental unit, and, of course, pulverised fuel or gas would do equally well. The water as it travels upwards through the coil is gradually raised to a higher and higher temperature, until when 90 per cent. of the total length has been traversed the critical temperature of steam 706° F. is attained the pressure being, of course, all the time 3200 lb. At this point the whole mass of the water in the coil, three times the volume when at 60° F., as already stated, is bodily and quietly converted into steam at the same volume without the absorption of latent heat, and therefore without ebullition. For the remainder of the travel in the coil the steam is then very slightly superheated to 720° F., and subsequently passed through a reducing valve, during which the temperature is lowered to 620° F. and into the superheater, being finally discharged from the latter at 1500 lb. pressure, and 850° F. It will then be used in a small high-pressure turbine, running at 20-25,000 revolutions per minute, exhausting at 200 lb., generating 350 kw. in the process, into an ordinary condensing turbine, giving a further 900 kw. down to 29 in. vacuum.

The enormous economy to be obtained by working at 1500 lb. and 850° F., will be apparent on studying the heat entropy or Mollier diagram, and in the chemical industry still further substantial economies would be possible by using exhaust steam from the second turbine at, say, 40 lb. pressure for heating and process work, or using one special turbine from 1500 lb. and 850° F., direct down to 40 lb., and little or no superheat. Further details will, therefore, be awaited with interest, as the work unquestionably represents a complete revolution in steam practice.

GRAPHITE AS A METALLIC MODIFICATION OF CARBON

The metallic character of an element is determined mainly by the presence of free electrons, which enable the element to conduct electricity without an accompanying transference of matter, make it a good conductor of heat, and produce its opacity and metallic lustre. In all these respects graphite is definitely metallic in character. It is highly opaque and lustrous, and reflects light without appreciable selective absorption; its electrical conductivity is greater than that of mercury, and the temperature co-efficient is the same in sign and magnitude as that of the majority of pure metals; its thermal conductivity at high temperatures is even greater than that of the metals. Chemically, also, graphite resembles the metals in being insoluble (without pronounced chemical change) in all solvents, with the exception of molten metals. The resemblance even extends to the power possessed by graphite of yielding the positive C···· ion in sufficient concentration to be electromotively active.—(*Chem. Ztg., Feb.* 27, 1924.)

FORTHCOMING EVENTS

Mar. 7. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*, the Engineers' Club, Coventry Street, W. 1, at 4.30 p.m. "Adsorbents: With Special Reference to Silica Gel," by Prof. E. C. Williams. "Activated Carbon," by Major V. F. Gloag. Dinner will be held at 6.45 p.m., and at 8 p.m. discussion on the two papers will commence.

Mar. 7. ROYAL COLLEGE OF SCIENCE CHEMICAL SOCIETY. Annual dinner at the Imperial College Union, Prince Consort Road, S.W. 7, at 7.15 p.m.

Mar. 7. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "Some Chemical Qualities of the Living Cell," by Prof. F. Gowland Hopkins.

Mar. 10. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 8 p.m. (Cantor Lecture.) "A Study of the Destructive Distillation of Coal," by E. V. Evans.

Mar. 10. THE CERAMIC SOCIETY, Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Improperly Pugged Clay, and its Effect on (a) the Wage-earning Capacity of the Operative, and (b) the Loss by Defective Ware to the Employer," by A. Hollins.

Mar. 10. BIOCHEMICAL SOCIETY. Annual General Meeting, the Lister Institute, S.W. 3, at 4.30 p.m. (1) "Demonstration of Method for Investigating Calcium and Phosphorus Metabolism in Rats," M. A. Boas. (2) "Variations in Growth-Promoting and Anti-Rachitic Value of Milk from the same Cow kept under Varying Conditions of Light and Diet," E. M. Luce. (3) "Influence of Diet and Management of the Cow upon the Calcium and Phosphorus Retention of Rats Fed upon the Milk," M. A. Boas and H. Chick. (4) "The Possible Significance of Hexosephosphoric Esters in Ossification: Part II. The Phosphoric-Esterase of Ossifying Cartilage," R. Robison and K. M. Soames. (5) "Part III. The Action of the Bone Enzyme on the Organic Phosphorus Compounds in Blood," H. D. Kay and R. Robison. (6) "The Effect of Insulin on the Phosphoric Esters Present in Blood and Muscle," H. D. Kay and R. Robison.

Mar. 11. INSTITUTION OF PETROLEUM TECHNOLOGISTS. Annual General Meeting at the Royal Society of Arts, John Street, Adelphi, W.C. 2, at 6 p.m. Address to be delivered by H. Barringer, M.I.Mech.E.

Mar. 11. ROYAL COLLEGE OF SCIENCE CHEMICAL SOCIETY. At 5 p.m., "Colloids," by H. D. Murray, B.A.

Mar. 12. INSTITUTION OF CIVIL ENGINEERS, Great George Street, Westminster, S.W. 1, at 7 p.m. Discussions on "CO_2 Recorders," introduced by C. E. Stromeyer, and "The Practical Testing of Steam Boilers," introduced by R. H. Parsons.

Mar. 12. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 8 p.m. "Personal Recollections of Some Notable Scientific Men," by A. A. Campbell Swinton, F.R.S.

Mar. 12. and 13. THE INSTITUTE OF METALS, Annual General Meeting, the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1, commencing at 10 a.m. and concluding at 5 p.m. each day. The following papers will be submitted:—(1) The Relation Between the Tensile Strength and the Electrical Resistivity of Commercially Pure Copper," W. E. Alkins. (2) "The Brittle Ranges in Brass as Shown by the Izod Impact Test," D. Bunting. (3) "The Cadmium-Lead-Zinc System," M. Cook. (4) "The Relative Corrosion of Zinc and Lead in Solutions of Inorganic Salts," J. Newton Friend. (5) "Determination of the Thermal Coefficients of Expansion of Some Commercial Metals and Alloys," J. Newton Friend. (6) "Copper-Zinc Alloys which Expand on Solidification," K. Iokibe. (7) "The Equilibrium Diagram of the Copper-Tin System," M. Isihara. (8) "The Constitution of the Alloys of Copper and Cadmium," C. H. M. Jenkins. (9) "X-Ray Studies on the Copper-Aluminium Alloys," E. R. G. P. Jette and A. F. Westgren. (10) "The Tensile Properties of Aluminium at High Temperatures," T. Martin. (11) "The Investigation of a Fatigue Failure of Brass Tubes in a Feed Water Heater—with a Consideration of the Nature of Fatigue," W. E. W. Millington and Prof. F. C. Thompson. (12) "The Effect of Casting Temperature on the Physical Properties of a Sand-Cast Zinc-Bronze," F. W. Rowe. (13) "The Aluminium-Copper Alloys. Alloys of Intermediate Composition," D. Stockdale. (14) Note on the Effect of Cold-Drawing and Annealing on Some Electrochemical Properties of a Low-Tin Bronze," H. J. Stuart Wilson.

Mar. 14. SOCIETY OF CHEMICAL INDUSTRY, *South Wales Section*, the Technical College, Mount Pleasant, Swansea, at 7.15 p.m. Joint discussion with the Faraday Society on "Slags and Fluxes in Melting and Refining, with Reference to the Problems of Slag Inclusions."

Mar. 17. BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY, the Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "Ionisation in Non-Aqueous Solvents," by R. L. Wormell, B.Sc.

Mar. 17. INSTITUTION OF THE RUBBER INDUSTRY, *Manchester Section*, Midland Hotel, Manchester, at 7.30 p.m. "Selling Rubber Goods," by Capt. E. E. Buckleton.

Mar. 17. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, W.C. 2, at 7 p.m. "Illuminating Engineering, its Application and Value to the Electrical Industry." Discussion to be opened by Messrs. L. Gaster and J. S. Dow.

Mar. 18. SOCIETY OF CHEMICAL INDUSTRY, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7.15 p.m. "The Fermentation of Cacao," by A. W. Knapp.

Mar. 18. THE HULL CHEMICAL AND ENGINEERING SOCIETY, Hull Photographic Society's Rooms, Grey Street, Park Street, Hull, at 7.45 p.m. "Anthracene and its Derivatives," by W. Thevenaz, Ph.D.

SOCIETY OF CHEMICAL INDUSTRY

GLASGOW SECTION

The fifth meeting of the session was held in the Institute of Engineers and Shipbuilders, Glasgow, on February 22.

Mr. W. E. Moodie occupied the chair, and a paper by Messrs. Walmsley and Stewart on "Notes on Continuous Causticising and Cresylic Acid" was read by Mr. Stewart.

The process outlined was one in operation in the chemical works department of the Corporation of Glasgow. The various stages in the continuous process for the production of caustic soda from soda ash by treatment with lime was first described. Attention was directed to the reversible nature of the essential reaction: $Na_2CO_3+Ca(OH)_2\rightleftarrows CaCO_3+2NaOH$ and to the fact that the production of caustic soda depended largely on the strength of the sodium carbonate solution. There was no advantage in obtaining the maximum causticity—a causticity of between 85 per cent. and 90 per cent. being ideal for the treatment of tar acids. In the continuous process the settling rate of the calcium carbonate was of prime importance and was governed by (*a*) the physical and chemical character of the lime used, (*b*) the conditions of mixing the reacting substances, and (c) the presence of organic impurities in the sodium carbonate solution. The rate of causticisation was much more rapid than generally supposed and varied from 3 to 15 minutes, according to whether the lime had been slaked before mixing or allowed to slake in the carbonate solution. The temperature of the carbonate liquor was also important as rapid settling was obtained with higher temperature.

A full description of the "Dorr" continuous causticising plant was then given. The presence of organic impurities in the liquors containing the regenerated sodium carbonate affected the texture of the cake of calcium carbonate produced and by so doing the process of filtering. The caustic solution was used in the treatment of tar oils. The resulting cresylate solution was allowed to settle, evaporated and carbonated with the waste gases—containing 80—90 per cent. of carbon dioxide—from the sulphate of ammonia plant. The carbonated liquors were allowed to settle and the regenerated sodium carbonate was, after settling, returned to the feed pans of the causticising plant. The extraction of cresylic acid was next described and the character of the acid was shown to depend to a considerable extent on the character of the mother tar.

The liability of unrefined tar acids to discoloration on exposure to light was commented upon. The discolorisation in alkaline solution was found to be due to the absorption of oxygen. It had been proved that on separating a distillate into two fractions, those distilling above and below 206° C., the lower boiling fraction would not, in alkaline solution, absorb oxygen to any extent. The higher boiling fraction did absorb oxygen. In works practice a certain amount of purification took place

as some of the bodies responsible for the discoloration dissolved in sodium carbonate solution, giving rise to a dark coloured alkaline liquid. The substances show the chemical characters of both acids and phenols and are soluble in water, which accounted for their presence in the drainage water from tarred road surfaces. It was suggested that the toxic character, towards fish, of such drainage water might be due to these substances.

The property, which cresylic acid possessed, of darkening in sunlight was detailed and shown to be due to two distinct reactions. (1) A slow development of a pink colour—of purely academic interest, and (2) a rapid development of a dark red colour—a property associated only with certain samples of cresylic acids. The mechanism of change was believed to be similar in the two cases.

An interesting catalytic action of "conditioned" metals was mentioned as being responsible for the production of a red colour. Freshly distilled samples of cresylic acid—of the darkening variety—turned red when boiled under a reflux condenser and in contact with a steel strip. The peculiar "pitting" action of cresylic acid upon aluminium was mentioned. A useful practical test to ascertain whether, or not, a sample of cresylic acid would darken on standing was given. An acid, which on warming with paraformaldehyde, did not darken in colour was not likely to undergo change on standing.

An animated discussion followed and largely centred round the disposal and value of the "cake" of calcium carbonate formed in the cauticising process. It was mentioned that this waste material could be used as a "filler" for tar preparations and also for agricultural purposes provided that it was sufficiently dried and of low caustic and phenolic content.

BRISTOL SECTION

At the meeting held on February 7, a paper entitled "Further Applications of Thallium Compounds. I. Thallous Hydroxide" was read by R. C. Menzies and E. M. Wilkins.

The convenient solubilities and ease of crystallisation of most organic thallous salts, the insolubility of the iodide, and the ready solubility of the hydroxide in water with formation of a strongly alkaline solution, make a standard solution of the hydroxide a reagent by means of which almost any acid may be titrated with simultaneous formation of a readily analysed salt. Thallous normal adipate and pimelate made in this manner are described, the latter being more readily soluble in water than the former. Dilute aqueous solutions of thallous palmitate and oleate behave as dilute soap solutions forming froths on shaking, only the oleate giving a froth permanent in the cold. Thallous oleate is soluble in ether. When salts of the alkali metals are too soluble for convenient preparation information as to their probable nature may be obtained by preparing the more sparingly soluble but generally isomorphous thallous salts. Thus the thallous salt of salicylaldehyde (m.p. 186° with decomposition) crystallises in yellow needles from a solution of salicylaldehyde in an equivalent amount of 10 per cent. (= ·0453N) aqueous thallous hydroxide, while the addition of acetone dicarboxylic ester to the same reagent in the cold causes the immediate formation of the crystalline monothallium salt.

On February 16 a successful dinner of the Bristol and South-Western Counties Sections of the Institute of Chemistry and of the Society of Chemical Industry was held at the Royal Hotel, College Green, under the chairmanship of Mr. M. W. Jones, supported by Messrs. W. J. U. Woolcock (general manager of the Association of British Chemical Manufacturers), R. D. Littlefield (H.M. Alkali Inspector), E. Halliwell and R. Robertson (Bristol Gas Co.), J. Bernard (manager, Netham Chemical Works), Prof. F. Francis, Prof. J. McBain, Dr. T. Howard Butler, Mr. A. Marsden and Mr. A. Wintle.

Following the loyal toast, the chairman regretted that Sir E. Cook had been prevented from attending by illness.

Mr. R. D. Littlefield, in proposing "The Society of Chemical Industry," outlined the history of the Society and said that the Society was recognised as the leader in all matters affecting the interests of the chemical industry and of those connected with it. The Society had life and vigour and so had the elements necessary to continue its vigorous existence. In reply, Mr. W. J. U. Woolcock, after reading a letter in which the President, Dr. E. F. Armstrong, F.R.S., regretted his inability to be present, spoke of the progess of the Society during the past year and said the Council was most anxious to obtain the closest co-operation between the Sections and the Council. After paying a tribute to the work of the Bristol Section, and to that of its hon. secretary, Mr. Marsden, Mr. Woolcock then discussed the need for informing the public, referring to the great demonstration of chemical industry and chemistry to be provided in the British Empire Exhibition, and the movement for *rapprochement* between scientific societies.

Prof. J. W. McBain then proposed "The Institute of Chemistry," paying a warm tribute to its work, and Mr. G. S. W. Marlow replied. Dr. T. Howard Butler proposed "The University of Bristol," to which Prof. F. Francis responded. A musical programme was provided.

CHEMICAL ENGINEERING GROUP

On February 26 a symposium was held jointly with the Institution of Mechanical Engineers on "The Treatment of Water for Industrial Purposes."

In the first paper, Mr. J. P. O'Callaghan described the sedimentation and filtration of turbid river water for works use, illustrating his remarks by means of the Beckton plant. This plant, one of the largest in use, deals with four million gallons of Thames water daily, and consists of four sedimentation basins of great efficiency and eight rapid sand filters of the gravity type. Lime is added in suitable proportions and the treated water is allowed 4 hours for reaction and sedimentation. By this means the Gas Light and Coke Co. relieves the

London water board from supplying over 1000 million galls. per annum. Mr. O'Callaghan then described softening by the lime-soda process, of which he showed the advantages to boiler users, and softening by the Permutit zeolite process.

Mr. B. Heastie, B.Sc., discussed the chief methods for the purification of water, viz., distillation, filtration, water softening by purification, softening by filtration through zeolites, and the use of boiler compounds. In conclusion the author considered physical purification by means of heat, the action of vacuum and by electrolysis, and the elimination of iron. The extraction of oil was treated under the heads of mechanical, chemical and electrolytic methods. The paper was richly illustrated by numerical and other data.

"Water Softening by Means of Doucil", was the title of the contribution by Messrs. T. P. Hilditch and H. J. Wheaton. The softening effect of natural zeolites was largely a surface action, so that only a small proportion of the soda content was utilised. If suitable porosity and surface could be secured, a base-exchanging compound could be made in which a much larger proportion of the combined soda could be utilised to produce soft water. This had been realised by Messrs. J. Crosfield & Sons, Ltd., who had discovered how to produce a complex silicate containing replaceable combined soda in the form of a dried gel. The dried product contained 13·3 per cent. Na_2O, 22·0 per cent. Al_2O_3, and 64·7 per cent. SiO_2; rather more than 3 per cent. of the soda was converted into non-exchangeable calcium silicate, and the remaining 10 per cent. could be completely replaced alternately by lime and soda. In practice and if completely softened water were required, about 40 per cent. of the exchangeable soda, or 4 per cent. of the weight of anhydrous doucil present, was exchangeable for lime before the doucil allowed appreciable quantities of calcium or magnesium salts to escape. The production and application of doucil were described in detail.

Mr. H. W. Coulson read a paper on "The Treatment of Condensing Water"; in which he discussed the use of water contaminated with minute organisms and showed how the use of a minute dose—sometimes as little as ½ part per million—of chlorine inhibited the formation of the jelly-like deposit that was otherwise produced, preventing heat transference, causing loss of vacuum, and entailing frequent cleaning. Experience gained in a number of power plants indicated that there was no danger of corrosion due to the chlorine, which, apparently, was at once absorbed by the organic matter in the water.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

At a meeting of the University of Birmingham Chemical Society, held on February 18, a paper was given by Mr. G. E. Forstner, B.Sc., on "Vitamins: their Chemistry and Importance to Life."

The speaker sketched briefly the growth of the idea of vitamins, discussed the work of Eykman and Hopkins, and showed how the three vitamins influence growth in animals. Vitamin B and beri-beri were then described, mention being made of the isolation of a very rich vitamin fraction, by Funk. Vitamin C was the least stable of the vitamins, and a deficiency of this in the diet was the cause of scurvy. Vitamin A and the deficiency disease rickets were dealt with. It was suggested that this vitamin may be of an aldehydic nature and contained no nitrogen. Vitamins were also of some importance in the vegetable world. Their influence on yeast growth and bacteria was mentioned and the effect of "auximones" on plant growth referred to.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

On February 11, the Fuels Group met under the presidency of Monsieur R. Etienne to discuss the refining of petroleum.

Monsieur A. Guiselin, member of the General Petroleum Committee, considered the necessity for the scientific extraction in France of petrol and oils from petroleum and the future of petroleum in Madagascar. The question of origin was lightly touched upon by the speaker, who traced the necessity for refining crude oils to yield petrol, paraffin, lubricants, fuel oils, etc. The first use of petroleum was for lighting as a substitute for shale oil, but further uses had been developed. If, during the initial period, only one quality of crude oils had been available, such results could not have been obtained, especially in the absence in those days of methods for separating or modifying the constituents. It is owing to the many qualities of natural oils that the variations in commercial needs could be met at the beginning, but in 1910 there was a crisis in the production of petrol which was avoided by the excess production of crude oils so that stocks of by-products grew apace. The war equalised matters by the great demand for residues, but later caused a new crisis owing to the enormous increase in the demand for petrol which had to be made either by recovery from natural gas or by cracking. At present equilibrium had not been established, and the refiners concentrated on the oil fields were profiting from the situation. Owing to this situation the consuming countries were affected by variations in the markets in neighbouring countries; thus France, requiring small amounts of residue, had to pay highly for them because England required a large amount. This dependence would be less felt were it possible to import crude petroleum from all sources and refine them as required. Monsieur Guiselin then discussed the report of the U.S. Geological Survey in 1921, and criticised the opinion therein expressed that exhaustion of the world's resources of petroleum was approaching. He then quoted figures from American literature to uphold the contrary argument. In discussing refining, the speaker pointed out that the American gallon varied in weight, and drew the conclusion that refining was immensely profitable to the American refiners and could be equally profitable to France were

crude oils refined there. He then considered the numerous advantages, technical, transport, economic, storage, of refining petroleum at the point of consumption. Concluding the first part of the address, Monsieur Guiselin discussed technical problems of refining, such as treatment of emulsions. In the second part of the address, the oilfields of Madagascar were discussed. These fields were discovered in 1899 by an engineer prospecting for coal, and since 1919 many efforts have been made to persuade the public authorities to pay attention to them.

Professor L. Bertrand then followed with a paper entitled "General considerations on the Bituminous Sands and Grits of Madagascar," which described the results of a mission carried out in Madagascar by the speaker and Monsieur Joleaud. It was concluded that these bituminous deposits were the residues of old oil-fields which had lost almost entirely the lighter oils owing to the fact that the triassic sands of that region had been long deprived of their former covering of more recent and impermeable strata. It seemed, he said, that there was little chance of finding petroleum in commercial quantity in regions where triassic sands are uncovered, an opinion borne out by borings in another locality. This, however, did not imply that no petroleum was to be found in Madagascar, as there was every reason to suppose that oil-fields did exist there, but a thorough geological study was needed of the region before exploration could be begun satisfactorily.

INTERNATIONAL CEMENT CONGRESS

The Institution of Structural Engineers is arranging to hold an International Cement Congress at the International Building Exhibition, Olympia, London, on Tuesday and Wednesday, April 22 and 23, 1924.

It is proposed that the following and probably other subjects shall be discussed during the course of the Congress :—

1. Ciment fondu in practice.
2. Surface dust on concrete floors in factories.
3. Cement in sea water.
4. Cement in concrete roads.
5. Preparations to withstand oil.
6. The influence of size and shape in compression test blocks.
7. Microscopy of cement.
8. Porosity of concrete blocks.
9. The use of sea water in mixing cement.

The papers in these subjects will be grouped and printed in advance so that when the Congress meets a group of papers may be taken as read and discussed without waste of time.

The hours of meeting of the Congress will be 11 to 1 and 3 to 5 on each day.

The Council of the Institution believes that this Congress will do much towards the solution of problems which confront chemists, engineers, manufacturers and others connected with the cement industry.

The Council of the Society of Chemical Industry has nominated Dr. Geoffrey Martin and Dr. David Prentice as its delegates to the Congress.

CORRESPONDENCE

THE PROFESSION OF CHEMISTRY AND ITS POSITION

Sir,—The Editorial in the issue of February 22 once again laments the fact that chemistry is not, as yet, a "closed" profession, and as usual, a comparison is made with the professions of law and medicine.

I venture to submit that this attitude is open to criticism which, though it may not be generally accepted, is, I maintain, not altogether unreasonable. There is but little real analogy either in its origin, or in its relation to the general public between the profession of chemistry and those of law and medicine, with which it is compared. The legal professions are actually "closed," for as is well known, they can only be practised by those who either have been called to the Bar or have passed the examinations of the Law Society. Its unique position is derived, no doubt, partly from its ancient association with Ecclesiastical Authority and partly from the privileges with which law makers, even in comparatively primitive states of society have hedged themselves about. It is in many ways an entirely unproductive profession (except to its practitioners) and its cost to the community is one of the overhead charges which are part of the price of a complicated state of society.

Medicine on the other hand, though for practical purposes largely a "closed" profession, is not absolutely so, for there is nothing to prevent anyone practising the art of healing, providing they do not hold themselves out to be legally qualified, though such unqualified practitioners are, of course, in a serious position if accidents happen in the course of their treatment.

The legal qualification to practise medicine is the entering of the name of the practitioner on the Medical Register of the General Medical Council, but there is this difference between medicine and law, that in the former there are several qualifications which entitle the holder to registration, for a degree in medicine of a British university and also the various diplomas of the Conjoint Colleges of Physicians and Surgeons and the Society of Apothecaries are, *ipso facto*, registrable. In passing it is worth remembering that these qualifications do not merely involve theoretical training, but also actual practical experience. The esteem in which the medical profession is held by the public is due to its intimate association with individuals, for they attend both to one's arrival and departure from this world, and their assistance is called in to deal with those "ills which human flesh is heir to."

No such conditions apply to the position of the profession of chemistry, nor are they likely to, for despite the admitted importance of chemical science to the community, the personal services of chemists are never likely to be required by the average member of the public.

It is therefore unlikely that the Legislature will take action to put the profession of chemistry into a position similar to that of medicine, for it would argue that the usual employers of chemists not being the

general public are or ought to be the best judges of what qualifications are desirable. In actual fact, in cases where chemists have to undertake statutory duties in official appointments—*i.e.*, Public Analysts and Official Agricultural Analysts—the profession is, for practical purposes, more or less closed, for it is now almost invariable for appointments to these positions only to be sanctioned by the Government Departments concerned when held by Fellows (or Associates) of the Institute of Chemistry.

It cannot be said therefore that the State has been altogether neglectful to provide for a standard of competence in practitioners of chemistry where the interests of the public demand such.

It may be doubted if excessive introspection is any more a healthy sign in a profession than it is in an individual, and the public, if they take any interest in this matter, may well think these continual complaints neither dignified nor reasonable, for in the end the status of a profession in the public esteem depends more on the attitude of its practitioners than on the intrinsic value of their services to the community.

In discussing the general position of the profession of chemistry it would be more reasonable to compare it with the profession of engineering. Both are of comparatively recent growth, and the relationship of the bodies granting diplomas are similar. In both cases it was realised in the early years that the academic training of the universities and colleges of university rank was not altogether adequate, and chartered bodies were organised within the professions with powers to examine and grant diplomas of competence, the qualifications for which required not only a high standard of theoretical knowledge, but also of practical professional work. There is, however, this difference, that in the case of chemistry there is only one body, the Institute of Chemistry, which grants diplomas in several branches of chemistry, whereas in the case of engineering there are different institutions such as those of the Civil, Mechanical and Electrical Engineers, each dealing with its own branch of the science. To this extent then the profession of chemistry is more united and better organised than is engineering.

In both cases the actual word "chemist" or "engineer" has a wide significance, and is used by many whom the chartered bodies would not recognise as in any way qualified practitioners of their science—in the case of chemists the position is unfortunately complicated by the Pharmacy Acts giving the title "chemist and druggist" to those who are legally on the register as qualified to sell and dispense poisons within the meaning of the Acts, so that to the general public the word "chemist" connotes the keeping of a pharmacy store. On the other hand, the gentlemen who quite recently held up the railway traffic of the country call themselves "Locomotive Engineers," though it is permissible to doubt if they could any more design a locomotive than could a chemist, whilst a plumber, whose business is expanding, blossoms out into a "Sanitary Engineer."

The word "profession" again offers some difficulty, for in its widest significance it connotes the art of publicly announcing one's skill in an art or science, and is quite loosely used—one has heard of "professional ratcatchers," Professor "So and So," the famous prestidigitateur, and so forth. In the case under discussion it is arguable that it is permissible to restrict the phrase "profession of chemistry," to connote only those who practise this science in virtue of holding the technical diploma of the chartered body—*i.e.*, The Institute of Chemistry.

It must be admitted that even if the phrase "profession of chemistry" be limited to this, it is not practical politics to attempt to limit the use of the word "chemist" to the same limited significance, at any rate without the voluntary reliquishment by the pharmacists of the claim to this title.

There are, of course, many distinguished "chemists," especially among the members of the teaching profession, holding academic qualifications of a high order who are not at present members of the profession of chemistry in the restricted sense indicated, but unless and until university degrees in chemistry involve definite practical professional training, in addition to theoretical knowledge, which, to return to the analogy of medicine, is fully comparable with the "clinical" experience necessary for a degree in medicine, it is perfectly reasonable to regard such as insufficient qualifications for membership of the profession of chemistry.

The Institute of Chemistry has already done much to open its portals to all *bona fide* chemists, indeed more than some members think altogether desirable. In the near future it may be hoped that all chemists worthy of the name will take these qualifications for it is increasingly probable that without them it will be impossible for a chemist to obtain a first-class post. This has already largely occurred in engineering, for in advertisements for engineers it will usually be seen that the applicants must hold the diploma of the appropriate chartered body.—I am, Sir, etc., C. L. CLAREMONT

247, Kennington Road
London, S.E. 11

INTERNATIONAL CHEMICAL RELATIONSHIPS

SIR,—Your columns are scarcely the place to indulge in a historical discussion, but editorial matter is legitimate game, and on February 29 your remarks contain much on which comment is needed.

With the motive and tone of your article no one can quarrel, and it is refreshing to find one of our leading technical journals recognising, what has long been forgotten, namely, that the search for knowledge should be above the barriers that divide nations from each other.

In your remarks on the relationship between French and German chemists you say, "During the last sixty years . . . now defend." There are two questions which must follow a comment like the one just quoted. Can any intelligent chemist anywhere, who has taken the trouble to study the history of the matter deny: (1) That in the Franco-Prussian war France got what she asked for, and richly deserved. (2) That the increasing mass of evidence goes to show that there is little to choose

between the culpability of France, Germany and other countries for the outbreak of 1914.

As for the fact of invasion, Germany was invaded by France's ally on her Eastern frontier in a manner which left nothing to be desired even by the most whole-hearted anti-German. The question of invasion is about as broad as it is long. International amity will never be secured while we maintain the fiction of a pariah nation who attempted to upset a number of friendly, innocent, unprepared neighbours, and no German chemist who is worth his salt will ever acquiesce in such a preposterous version of what occurred.

It is interesting to observe how the passion for investigation and truth seems to leave scientific men of all nations when they deal with matters outside their own science. Why, say on a matter like the origins of the war, is it left to a historian like Mr. Gooch to display the real scientific attitude while scientists display all the prejudice and partisanship which one associates with the street corner rather than with men whose life work is the careful pursuit of knowledge.

One recent instance of this attitude occurs in Mellor's recent "Inorganic Chemistry," where, in dealing with the Stassfurt deposits (p. 428, vol. 2), the author disfigures his book by introducing a wholly irrelevant comment on the origins of the recent war, which merely shows that on matters outside his own province the author is as unscientific as he well can be. Truly the fact that a man is a great chemist does not mean that he is a great scientist.—I am, Sir, etc.,

Wallsend-on-Tyne T. WALLACE

SIR,—The writer has read your "Editorial" in the issue of February 29 with a good deal of interest. Do you not think that your suggestion rather tends to show that, as a matter of fact, German scientific men are still of the same opinion as they were in 1913 or 1914? Surely, for a really repentant man, a suggestion such as you offer is unnecessary. If the man is repentant, he will confess and acknowledge that he has done amiss, without undue prompting. Do you not think that your "Editorial" might be misconstrued by the French, who have been invaded considerably oftener than twice by the German nation, and whose attitude is one of ineradicable suspicion? They would probably say that writing such as yours cannot be its own reward. And offers such as yours would make things worse. The writer's recollection is that Germany and France have fought considerably more than 30 or 40 times in the last 500 years, and in the majority of these cases France has been invaded.

Before the war, the writer has been told by Germans, in his own office, that we were a dying nation; that Germany intended to occupy our place, and that of France; that force was the only argument that really mattered. It is impossible to deal with this idea, except by meeting it on its own ground.

The writer very diffidently ventures to suggest that we are here as a nation to do judgment and justice, and neither of these have been accomplished. Germany has not yet suffered to anything like the extent she made other nations suffer. She has not yet made adequate restitution, or repayment, or done anything, except attempt to evade the consequences of her actions. She has appealed to force, and until she is compelled, by force, to feel retributive justice, she will be unrepentant. Offers like your own—no matter how well-meaning—will simply be used as an argument for escaping the penalties she should be compelled to pay. As a chemist, you will understand that the balance should be equipoised—that is justice. No correct analysis can be given if that fundamental law were trifled with—and you cannot speak about mercy unless it is founded on justice. The writer says this while bearing in mind the verdict of the Roman General, who summed up the Teutons in his day: "Cunning in ferocity; born to lie." It would seem that this strain of mentality is not yet extinct in the German "Republic," and it would be well to think of it in making any suggestions of the kind you have done. In other words, Germany must first of all prove by deeds, and not by letters, that she is willing to recompense all those countries she treated so barbarously. Apparently, you seem to have some faint agreement with the writer in your remarks on the Hamburg declaration of The Association of Tropical Diseases. This is hardly a sign of a repentant race, is it? And what effect would the letter you suggest, signed by a dozen scientific men, have on a nation like France, and to what extent would it represent the seventy millions of people who constitute Germany?—I am, Sir, etc.,

Wolverhampton T. MOORE HICKMAN

[We do not think our columns are suitable for the discussion of history or foreign politics; if any correspondents can make suggestions for more cordial relations between foreign chemists we shall welcome them.—ED.]

THE EPILATION OF SKINS

SIR,—When we have lived for another 5000 years we may be in a better position to judge whether Mr. Jerome Alexander's mummies are better than those of the Ancient Egyptians. His criticism of my knowledge of rigor mortis would be fairer if he quoted my remarks more fully and did not leave out a subsequent sentence "and probably other times as well," which supplies the omission he complains of. But my paper was not a dissertation on rigor mortis, information on which can be found in textbooks on physiology; it merely outlined the connexion between rigor mortis and its resolution with epilation and bating.

While all leather workers appreciate Mr. J. T. Wood's unbounded zeal for research it is obvious that, neither he nor any other individual could have made himself thoroughly acquainted with all the highly technical sciences concerned. It is not surprising, therefore, that he begins his criticism of a medical subject with a "howler." He demands the word "depilation" which means pulling the hair down. An animal has to be described as standing in a certain posture (*e.g.*, man at attention). We cannot pull the hair down from the top of his head any

more than we can pull the epidermis up from the soles of his feet. The skin is the outermost organ of the body not the uppermost or lowermost. Therefore the hair can, anatomically, only be pulled out. It is as easy to be accurate as inaccurate and saves confusion in science. Mr. Wood's second "howler" is "bacterial trypsin." Shade of Pasteur! Trypsin is a name given to a specific enzyme system made by an animal's pancreatic gland and has nothing to do with bacteria which are vegetable organisms. His third "howler" is to misquote my nomenclature and thus attempt to make it appear that I, also, am not conversant with my subjects. I do not think it just for him to misquote people, especially when he is criticising the quotation.

His statement that I "had no knowledge of tanning" may or may not be true, but what has that got to do with it? Tanning is not mentioned in my paper. Why Mr. Wood should choose me to hurl this onslaught at I do not know; I have never yet expressed any knowledge about tanning. I fancy that he must be thinking of somebody else.

He goes on to say that I am not telling the truth in my paper but produces no evidence to bear out his accusation. In my paper I have been frank and open, describing not theories, as he alleges, but experimental facts as lucidly as I can so that anybody, including Mr. Wood, can repeat the experiments. Yet he does not do this, but merely produces statements. For instance, he has examined the limes and has found few enzymes there. But we are vouchsafed no details; we do not know what tests he refers to or which class of enzyme he has tested for. Completely ignoring my experiments he declares that ammonia will unhair a hide, yet he does not tell us what precautions were taken to remove or stop the action of thrombase at the hair-roots. One can put skin into ammonia as I described, but that is no proof that it is the ammonia which is doing the unhairing. Perhaps Mr. Wood will be kind enough to give us the technique for the exclusion of thrombase and saproprotease from the experimental "ammonia unhairing" to which he refers.

Mr. Wood's strictures about the medical profession will cause them to listen to him when he can tell them something new about the chemistry of childbirth or even lupus of the skin. He will then also hear of Hunter's famous advice to Jenner to "Be accurate." It is as important to be as accurate in controversy as in nomenclature, and to place, as I have done in my paper, one's cards on the table. As I have tried to demonstrate experimentally, the blood in the skin is a valuable agent for the tanner. Blood is probably the most important and powerful chemical in the world, yet I have not seen the word given even a line in a leather chemist's index, in spite of the fact that tanners deal with an organ which has recently been an elaborate living structure—the skin.

Mr. Wood refers me to a paper by Mr. Collett, which only seems to refute Mr. Wood's former finding about the bacterial infectivity of the limes.—I am, Sir, etc., H. C. Ross

Liverpool

PERSONAL AND OTHER NOTES

Prof. W. H. Perkin, F.R.S., Waynflete Professor of Chemistry in the University of Oxford, has been elected to the board of the British Dyestuffs Corporation, Ltd. Prof. Perkin has for some time supervised the research department of the Corporation, and he will continue to do so whilst serving as a director.

Dr. J. I. O. Masson, M.B.E., reader in organic chemistry in the University of London, has been appointed a fellow of University College, London.

Sir Arthur Duckham, the well-known authority on the carbonisation of coal, is at present visiting the United States in connexion with the development of carbonisation in that country.

On February 15, the degree of D.Sc. was conferred on Mr. F. A. Freath, director of the scientific laboratory of Messrs. Brunner, Mond and Co., by the University of Leyden for a thesis on "The Ternary and Quaternary Equilibria in the System Sodium Perchlorate—Ammonium Sulphate—Ammonium Perchlorate—Sodium Sulphate—Water."

The retirement of Dr. H. J. H. Fenton, of the University Chemical Laboratory, Cambridge, is announced.

It is reported that Mme. Curie has been given the freedom of the City of Warsaw in recognition of her researches on radium.

The Council of the Royal Society has decided to recommend for election in the Society the following candidates:—Dr. T. N. Annandale, Mr. J. E. Barnard, Prof. J. F. Gemmill, Dr. M. H. Gordon, Prof. P. Groom, Dr. C. K. Ingold, Prof. P. F. Kendall, Prof. L. V. King, Prof. L. J. Mordell, Dr. T. Slater Price, Prof. C. V. Raman, Prof. L. J. Rogers, Dr. Alexander Russell, Prof. C. Spearman, and Dr. F. Twyman.

Mr. Theodore Rendle has taken up the appointment of technical works manager to Messrs. Chivers and Sons, Ltd., Histon, Cambridge. Up to the present, Mr. Rendle has acted as technical consultant to the group of polish manufacturers associated with Messrs. Hargreaves Bros. & Co., Ltd., of Hull, being a director of Hargreaves (London), Ltd., and chief chemist to Messrs. E. Brown and Son, Ltd., Manufacturers of Meltonian Polishes.

Protest against the Proposed Anglo-German Dyestuffs Agreement

A protest against the proposed agreement between the British Dyestuffs' Corporation and the Interessen-Gemeinschaft was made by a deputation from the British Association of Chemists, which was received by the President of the Board of Trade, the Rt. Hon. Sidney Webb, M.P. The deputation, which was introduced by Mr. C. S. Garland, consisted of Messrs. J. T. Allpas, J. Barr, E. M. Marchant and A. Stewart Mills.

Mr. Sidney Webb expressed his pleasure at meeting the representatives of the chemical profession, and expressed the view that the present Government had the greatest sympathy and appreciation of the labours of scientific workers. The future, not only of this nation but of civilisation, was to a large extent in their hands, and the problem facing statesmen of all countries was that of reconciling scientific progress with the social and economic aspirations of the community. He was not at all certain whether

members of the deputation present were in possession of that solution of all economic problems, the application of the infinite resources of atomic energy to production and social needs, but he was conscious that it was in the direction of the utilisation of hitherto undiscovered forces that progress would be made, and he was confident that the world in the year 2000 A.D. would be as different from the world of 1924 as the world of to-day differed from that of a century ago. He did not visualise in the immediate future the possibility of scientific men being placed in control of the whole administrative machine; the scientific man must for a long time at least depend upon the lay administrator and the representatives of democracy, politicians, liaison officers, and the interpreters of the conscious consent of democracy.

Members of the deputation expressed their concern for the future of the organic chemical industry if the terms of the proposed agreement were correct. The possibility of the British Dyestuffs Corporation becoming the mere agents for the United Kingdom for the I. G. must have a disastrous effect upon the industry in this country, and completely reverse the policy of H.M. Government with regard to the building up of the industry which was regarded as one of our first lines of defence in peace and war. The dyestuffs industry was the only training ground for technological chemists. The dyestuffs industry was not merely concerned with the manufacture of dyestuffs, but was at the basis of the whole organic chemical industry with its innumerable products applied to services of the community in the most diverse spheres. The comparative failure of the British Dyestuffs Corporation was attributed to the want of appreciation of science and the attitude of hostility to the technical directors of the Board by those whose interests were purely commercial, and a plea was made for the strengthening of the scientific direction of the Corporation. In marked contrast to the failure of the British Dyestuffs Corporation figures were given where the dyestuffs industry of this country had carried on successfully and profitably under the direction of scientific men. In one case production had been quadrupled since the year 1920, and the scientific staff correspondingly increased. It was emphasised that the superiority of the German Dyestuffs Corporations was due to the scientific direction and appreciation of scientific work in Germany, and that if the same condition prevailed in this country we need not fear German competition, given the necessary protection which has been promised under the provision of the Dyestuffs Act.

In reply it was stated that no definite agreement had been submitted to the Board of Trade, and that before any such statement could be ratified it would have to be ratified by the shareholders of the British Dyestuffs Corporation at a general meeting, and would require the approval of H.M. Government. Before that approval could be given full consideration would be given to all parties interested. A full consideration would be given to the points now raised by members of the deputation and the interests of dyestuffs makers other than the British Dyestuffs Corporation.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

In spite of labour troubles the demand for heavy chemicals is well sustained, but there are no fundamental changes in prices to report. The effect of the revision of the German reparation levy is somewhat obscure, and it remains to be seen whether the rebate of the duty will be counterbalanced by the increased cost of manufacture, caused partly by the stabilisation of the currency.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5½d. per lb.
Potass. Chlorate	3d.—3¼d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis ..	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide ..	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb., according to

Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.

Arsenic Sulphide, Yellow 1s. 11d. per lb.

Cadmium Sulphide .. 4s. per lb.

Carbon Bisulphide .. £24—£26 10s. per ton according to quantity.

Carbon Black .. .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.

Carbon Tetrachloride .. £56 per ton, drums free.

Chromium Oxide .. 1s. 3d. per lb.

Indiarubber Substitutes, White and Dark — 5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.

Lamp Black .. .. 40s. per cwt., barrels free.

Lead Hyposulphite .. 7½d. per lb.

Lithopone .. .. £22 10s. per ton.

Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.

Sulphur .. .. .. £10—£12 per ton, according to quality.

Thiocarbanilide .. .. 2s. 9d. per lb.

Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.

Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but those are the only products in this section which show any activity.

Acetate of Lime—

Brown .. .. .. £14 10s. per ton d/d. Demand active.

Grey .. .. .. £21 per ton.

Liquor .. .. .. 9d. per gall. 32° Tw.

Charcoal .. .. .. £7 5s.—£9 10s. per ton, according to grade and locality. Market steady.

Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. " " 24° Tw.

Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.

Wood Creosote .. .. 2s. 7d. per gall. Unrefined.

Wood Naphtha—

Miscible .. .. 5s. per gall. 60% O.P. Dull market.

Solvent .. .. 5s. per gall. 40 % O.P. Dull market.

Wood Tar .. .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.

Brown Sugar of Lead .. £47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—

Crystals .. .. 7¾d.—8d. per lb. Better demand, and firmer market.

Crude 60's .. .. 1s. 10d.—2s. per gall. Firmer, with more inquiry.

Acid Cresylic, 97/99 .. 1s. 11d.—2s. 1d. per gall. Steady. Increasing business and numerous inquiries.

Pale 95% .. .. 1s. 10d.—2s. per gall. Steady demand.

Dark .. .. .. 1s. 11d. per gall. Steady business.

Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—

Strained .. .. 10d.—11d. per gall. Very quiet.

Unstrained .. .. 8½d.—9d. per gall.

Benzole—

Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.

Standard Motor .. .. 1s. 4½d.—1s. 6d. per gall. ex work. in tank wagons.

Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.

Pure .. .. 1s. 8d.—1s. 11d. per gall.

Xylol coml. .. .. 2s. 3d. per gall.

Pure .. .. 3s. 3d. per gall.

Creosote—

Cresylic 20/24% .. 11d.—11½d. per gall. Few inquiries

Middle Oil .. .. }
Heavy .. .. .. }
Standard Specification } 8½d.—10d. per gall. according to grade and district. Market quieter.

Naphtha—

Crude .. .. 8d.—9d. per gall.
Solvent 90/160 .. 1s. 1d.—1s. 3d.
Solvent 90/190 .. 1s. 1d.—1s. 3d.
} More inquiry. Prices show upward tendency.

Naphthalene Crude—

Drained Creosote Salts £7—£8. Fair business.

Whizzed or hot pressed £10—£14 per ton. Price nominal. No business.

Naphthalene—

Crystals .. .. £16 10s. per ton.

Flaked .. .. .. £17 per ton.

Pitch, medium soft .. 60s.—70s. per ton. More enquiry. Prices hardening.

Pyridine—90/140 .. 15s.—15s. 6d. per gallon. More demand at higher prices than of late. In the South as much as 17s. 6d. has been quoted.

Heavy .. 11s.—12s. Steady with fair business.

INTERMEDIATES AND DYES

Business in dyestuffs is maintained, but without much improvement. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.

Acid H. .. .. .. 4s. 6d. per lb. 100% basis d/d.

Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.

Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.

Acid Salicylic, tech. .. 1s. 4d.—1s. 5d. per lb. Steady demand.

Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.

Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.

Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.

Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.

Antimony Pentachloride 1s. per lb. d/d.

Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.

Benzyl Chloride 95% .. 1s. 3d. per lb.

p-Chlorphenol .. .. 4s. 3d. per lb. d/d.

p-Chloraniline .. .. 3s. per lb. 100% basis.

o-Cresol 29/31° C. .. 5d. per lb. Demand moderate.

m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.

p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate

Dichloraniline .. .. 3s. per lb.

Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.

p-Dichlorbenzol .. .. £75 per ton.

Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.

Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.

Dinitrobenzene .. .. 9d. per lb. naked at works.

Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.

Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.

Diphenylamine .. .. 3s. 3d. per lb. d/d.

Monochlorbenzol .. .. £63 per ton.

a-Naphthol .. .. 2s. 6d. per lb. d/d.

β-Naphthol .. .. 1s. 1d. per lb. d/d.

α-Naphthylamine	1s. 5d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 5d. per lb. d/d.
Nitrobenzene	5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. per lb. 100% basis d/d
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 7d. per lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The principal items are in good demand for home trade and export orders generally show some indication of an improvement, which is expected to continue.

Acid, Acetic 80% B.P.	£52 per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 9d. per lb. Weaker tendency.
Acid, Benzoic	Commercial acid 2s. 9d. per lb. B.P. quality remains scarce at 4s. per lb.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	18s.—20s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5% for ton lots. Market firm.
Acid, Gallic	3s. per lb. for pure crystal. Steady market.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	English make, 2s. 3d. per lb., which is below the price of imported material.
Acid, Tannic	3s. 0d. per lb. for B.P. quality.
Acid, Tartaric	1s. 1d.—1s. 1¼d. per lb. less 5%. Firmer with more demand. Continental acid offered at 1s per lb. less 5% c.i.f. U.K. port.
Amidol	9s. per lb. d/d.
Acetanilide	3s. per lb. Weak.
Amidopyrin	13s. 3d. per lb. Demand negligible.
Ammon. Benzoate	3s. 9d. per lb. English make.
Ammon. Carbonate B.P.	£35 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Market neglected.
Barbitone	15s. per lb. Weak market.
Benzonaphthol	6s. per lb. Firmer.
Bismuth Salts	A steady market. Prices according to quantity;
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9d.—10d. } Uncertain market.
Sodium	9½d.—10d. }
Ammonium	11d.—1s. }
Calcium Lactate	2s. 6d. per lb. for [illegible] English make. Prices reduced.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots.
Creosote Carbonate	6s. 0d. per lb. Little demand.
Guaiacol Carbonate	12s. 6d. per lb. for small stocks.
Hexamine	3s. 9d. per lb. for foreign make. Weaker. Large supplies available.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B. P.	55s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Prices reduced. Market quiet.
Red oxide	4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	3s.—3s. 1d. „
White precip.	4s. 1d.—4s. 2d. „
Calomel	3s. 5d.—3s. 6d. „
Methyl Acetanilide	20s. per lb.
Methyl Salicylate	2s. 9d.—2s. 10d. per lb. for carboys. Slightly easier.
Methyl Sulphonal	24s. per lb. Scarce.
Methylene di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 4d.—1s. 8d. per lb. Cheaper.
Phenacetin	7s. per lb. Dull.
Phenazone	7s. 9d. per lb. for cwt. lots. Spot prices much lower than forward offers.
Phenolphthalein	7s. 6d. per lb. Firm.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s.—90s. per cwt., less 2½%. Firm market. Inquiry good.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	8½d.—9d. per lb. for B.P. crystal English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. 3d. per lb.
Salol	4s. per lb. Price fluctuates.
Silver proteinate	10s. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite— Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	76s. 6d.—81s. 6d. per cwt., according to quantity. Prices reduced
Sod. Salicylate	Powder 2s. 9d.—2s. 10d. per lb. Crystal at 2s. 10d.—2s. 11d. per lb Market weaker.

Sod. Sulphide—		
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.	
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.	
Sulphonal	18s. 6d. per lb.	
Tartar Emetic	1s. 4d. per lb.	
Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed.	

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	13s. 6d. „	
Amyl Acetate	3s. „	
Amyl Butyrate	7s. 3d. „	
Amyl Salicylate	3s. 6d. „	
Anethol (M.P. 21/22° C.)	3s. 9d. „	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. „	
Benzyl Alcohol free from Chlorine	3s. 3d. „	
Benzaldehyde free from Chlorine	3s. 6d. „	
Benzyl Benzoate	3s. 9d. „	
Cinnamic Aldehyde Natural	17s. 6d. „	Cheaper.
Coumarin	21s. „	
Citronellol	16s. „	Much cheaper.
Citral	10s. „	
Ethyl Cinnamate	10s. „	
Ethyl Phthalate	3s. 9d. „	
Eugenol	10s. 9d. „	
Geraniol (Palmarosa)	35s. „	Cheaper.
Geraniol	10s.—17s. 6d. per lb.	
Heliotropine	9s. per lb.	
Iso Eugenol	15s. 9d. „	
Linalol ex Bois de Rose	20s. „	
Linalyl Acetate	20s. „	
Methyl Anthranilate	9s. 6d. „	Advanced.
Methyl Benzoate	6s. „	
Musk Ambrette	52s. 6d. „	
Musk Xylol	20s. „	Advanced.
Nerolin	4s. „	
Phenyl Ethyl Acetate	10s. „	
Phenyl Ethyl Alcohol	16s. „	
Rhodinol	62s. 6d. „	
Safrol	1s. 10d. „	
Terpineol	2s. 9d. „	
Vanillin	26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	1s. 11d. „	
Bergamot Oil	15s. 6d. „	Dearer.
Bourbon Geranium Oil	29s. 6d. „	
Camphor Oil	75s. per cwt.	
Cananga Oil, Java	9s. 4½d. per lb.	
Cinnamon Oil, Leaf	Very little offering.	
Cassia Oil, 80/85%	9s. 9d. per lb.	
Citronella Oil—		
Java 85/90%	4s. 10d. „	
Ceylon	3s. 7½d. „	
Clove Oil	8s. 7½d. „	
Eucalyptus Oil 70/75%	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil	3s. 1d. „	
Lemongrass Oil	2½d. per oz.	
Orange Oil, Sweet	12s. 6d. per lb.	
Otto of Rose Oil—		
Bulgarian	27s. 6d. per oz.	Much cheaper.
Anatolian	21s. per oz.	„
Palma Rosa Oil	18s. 6d. per lb.	
Peppermint Oil—		
English	70s. per lb.	
Wayne County	18s. per lb.	Advanced.
Japanese	15s. per lb.	Advanced.
Petitgrain Oil	9s. 6d. per lb.	
Sandal Wood Oil—		
Mysore	25s. per lb.	
Australian	21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY

Applications

Brooke, and Woodall-Duckham, Ltd. Centrifugal separators. 4401. Feb. 20.

Dempster and Sons, and Toogood. Regenerator furnaces. 4545. Feb. 22.

English Grains Co., and McConechy. Drying apparatus. 3528. Feb. 11.

Evans (Allgem. Elektrizitäts-Ges.). Furnace. 4704. Feb. 23.

Farbenfabr. vorm. F. Bayer u. Co. Apparatus for producing intimate mixture between gases and liquids. 3782. Feb. 13. (Ger., 6.4.23.)

Fothergill. Evaporators. 3968. Feb. 15.

Green. Refrigeration etc. 3837. Feb. 14.

Hoenan and Leek. Separation of solid matter from gases. 3868. Feb. 14.

Higgins. Apparatus for separating liquids of different specific gravities. 4598. Feb. 22.

Imray (Meister, Lucius, u. Brüning). Expelling volatile substances by means of a stream of vapour. 4281. Feb. 19.

Jackson (Burn and Co.). Kilns. 4145. Feb. 18.

Leach. Refining-apparatus. 4505. Feb. 21. (U.S., 21.2.23.)

McLeod. 3589. *See* II.

Marks (Polysius). Drying sludge. 3534. Feb. 11.

Pfisterer. Apparatus for washing, mixing, and saturating fluids. 4373. Feb. 20.

Pfisterer. Apparatus for mixing etc. 4378. Feb. 20.

Phillips. Apparatus for cooling substances, liquids, or gases. 4521. Feb. 21.

Stehli. Sintering-machines. 3670. Feb. 12.

Thermokept Corp. Vacuumising liquids. 3526. Feb. 11. (U.S., 17.2.23.)

Complete Specifications Accepted

30,318 (1922). Arbuckle. Separating the liquid and solid components of mixtures. (210,855.) Feb. 20.

31,157 (1922). Lamplough and Harper. Retorts or stills. (211,219.) Feb. 27.

33,777 (1922). Appareils et Evaporateurs Kestner. Combined digesting and evaporating process. (204,670.) Feb. 27.

4842 (1923). Akt. de Norske Saltverker. Production of coarse precipitates from solutions. (194,676.) Feb. 20.

8641 (1923). Hunt (Reynolds). Centrifugal decanting or clarifying apparatus. (211,030.) Feb. 20.

10,461 (1923). Imray (Aquazone Corp.). Apparatus for dissolving gases. (211,371.) Feb. 27.
12,271 (1923). Bethune. Apparatus for condensing distilled vapours. (197,341.) Feb. 20.
13,842 (1923). Algem. Norit Maatsch. Treating liquids with purifying and decolorising agents. (198,366.) Feb. 27.
22,703 (9123). Aktiebolaget Separator. Centrifugal separators. (204,046.) Feb. 27.

II.—FUEL; GAS; DESTRUCTIVE DISTILLATION; MINERAL OILS; LIGHTING

Applications

Atkinson, and Stein and Atkinson. Gas-producers. 4367. Feb. 20.
Black. Manufacture of liquid fuel. 4559. Feb. 22.
Boughton. Manufacture of coal gas. 4523. Feb. 22.
Donald. Drying peats etc. 4111. Feb. 18.
Ges. f. Chem. Produktion. Manufacture of highly-active absorption carbon. 4628. Feb. 22. (Czecho-Slov., 22.2.23.)
Humphrey, and Synthetic Ammonia and Nitrates, Ltd. Manufacture of combustible gases. 4649. Feb. 23.
Mackay. 3896. *See* IX.
McLeod. Cylindrical rotating retort. 3589. Feb. 12.
Montgomorie. 4358. *See* IX.
Potts (N. V. Algem. Norit Maatsch.). Manufacture of active carbon. 4529. Feb. 22.
Schwarz. Treatment of hydrocarbons. 3785. Feb. 13. (U.S., 13.2.23.)
Shore. Conversion of heavy to light hydrocarbons. 3742. Feb. 13.

Complete Specifications Accepted

30,678 (1922). Gas Research Co. Gas-generators. (199,695.) Feb. 27.
32,136 (1922). Woodroffe and Scott. *See* XXIII.
32,926 (1922). Dobson, and Sugden and Co. Regenerative furnaces for gas production etc. (211,267.) Feb. 27.
2642 (1923). Kroll. Cracking petroleum products. (210,972.) Feb. 20.
9181 (1923). Dicker (S.E. Co.). Destructive distillation of shale etc. (211,033.) Feb. 20.
9514 (1923). Reitmayer, and Brunner Ges. Continuous distillation of wood. (211,368.) Feb. 27.
18,343 (1923). Gas Light and Coke Co., and Noden. Rotary scrubbers and washers for gas manufacture etc. (211,409.) Feb. 27.
18,365 (1923). Meister, Lucius, u. Brüning. Manufacture of highly-active charcoal. (200,839.) Feb. 27.
21,100 (1923). Ruhr. Apparatus for distilling coal etc. (208,117.) Feb. 27.

III.—TAR AND TAR PRODUCTS

Applications

Schwarz. 3785. *See* II.
Stewart and Walmsley. Purification of cresylic acid. 3702–3. Feb. 13.

Complete Specification Accepted

32,174 (1922). Vivian. Treatment of tar and like liquid hydrocarbons. (210,909.) Feb. 20.

IV.—DYESTUFFS AND INTERMEDIATES

Applications

Bates, Brightmore, and Webber. Manufacture of nitro derivatives of the chlorohydroxytoluenes. 4082. Feb. 18.
British Dyestuffs Corp., Clemo, and Perkin. Manufacture of gamma-tetrahydroquinolone etc. 3642. Feb. 12.
Clayton, Stokes, and Holliday and Co. Colouring matters of the pyrazolone series. 3704, 3710–1. Feb. 13.
Hall, and Silver Springs Bleaching and Dyeing Co. Manufacture and application of dyestuffs. 4542. Feb. 22.
Hereward, Thomas, and Scottish Dyes, Ltd. Production of hydroxyanthraquinones. 4173. Feb. 18.
Imray (Meister, Lucius, u. Brüning). Manufacture of vat dyestuffs. 4281. Feb. 19.
Knecht and Muller. Dyestuffs. 3828. Feb. 14.
Soc. Chem. Industry in Basle. Manufacture of thionaphthisatin etc. 3548. Feb. 11. (Switzerland, 18.7.23.)
Sokal (Kallo u. Co.). Manufacture of vat dyestuffs. 4079. Feb. 16.

Complete Specifications Accepted

21,276 (1922). Davies, Thomson, Thomas, and Scottish Dyes, Ltd. Production of colouring matters. (210,703.) Feb. 20.
30,923 (1922). Imray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs and chromium compounds thereof. (210,890.) Feb. 20.
31,254 (1922). Imray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs. (211,223.) Feb. 27.
31,595 (1922). Lowcock, Voss, and Gas Light and Coke Co. Manufacture of sulphurised dyes from carbazole-derived indophenols. (211,234.) Feb. 27.
2282 (1923). Marris, and Walker and Sons. *See* XV.
11,985 (1923). Soc. Chim. de la Grande-Paroisse. Manufacture of green dyestuffs dyeing in reduction-baths. (199,706.) Feb. 20.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER

Applications

Barrett, Coward, and Tootall Broadhurst Lee Co. Cellulosic material and manufacture thereof. 3606. Feb. 12.
Harbens, Ltd., Leon, and Sharrat. Manufacture of artificial silk. 3532. Feb. 11.
Marks (Bemberg A.-G.). Manufacture of artificial silk. 3989. Feb. 15.
Moeller. Treating waste paper. 4012. Feb. 16.
Nebrich. Production of paper pulp. 4316. Feb. 19.
Soc. Anon. La Cellophane. Drying cellulose films. 3563. Feb. 11. (Fr., 12.2.23.)
Soc. de Brevets Textiles. Improving vegetable fibres. 3501. Feb. 11. (Ger., 14.2.23.)
Tubize Artificial Silk Co. of America. Manufacture of artificial silk. 4678. Feb. 23. (U.S., 24.2.23.)

Complete Specifications Accepted

2282 (1923). Marris, and Walker and Sons. *See* XV.
10,213 (1923). Heberlein u. Co. Improving vegetable fibrous materials. (196,298.) Feb. 27.
14,503 (1923). Meister, Lucius, u. Brüning. *See* VI.
22,583 (1923). Dobler. Manufacture of paper. (205,793.) Feb. 20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING

Applications

Courtaulds, Ltd., and Whittaker. Dyeing artificial silk. 4604. Feb. 22.
Hall and others. 4542. *See* IV.

Complete Specifications Accepted

24,746 and 29,321 (1922). Plauson's (Parent Co.), Ltd. (Plauson). Dyeing. (211,178.) Feb. 27.
28,139 (1922). Russell. *See* XIV.
30,460 (1922). Grant. Waterproofing processes for fabrics. (210,865.) Feb. 20.
10,017 (1923). Usines de Keukelaere. Apparatus for dyeing bobbins of combed wool. (211,370.) Feb. 27.
14,503 (1923). Meister, Lucius, u. Brüning. Production of colour effects on paper and fabrics. (198,693.) Feb. 20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS

Applications

Bichowsky and Harthan. Production of cyanogen compounds. 3766. Feb. 13.
Brown. 4175. *See* XIII.
Canada Carbide Co., and Freeman. Manufacture of sodium sulphide. 3800. Feb. 14. (U.S., 14.2.23.)
Carpmael (National Electrolytic Co.). Manufacture of chromates. 3993. Feb. 15.
Chemical Engineering and Wilton's Patent Furnace Co., Wilton, and Wilton. Manufacture of sulphate of ammonia. 4397. Feb. 20.
Crosland. Kiln for calcining lime etc. 4055. Feb. 16.
Fabr. de Prod. Chimiques de Thann et de Mulhouse. Manufacture of cyanides. 3961. Feb. 15.
Johnson (Badische Anilin u. Soda Fabr.). Manufacture of hydrocyanic acid and cyanides. 4284. Feb. 19.
Lande, and N. V. Industrieele Maatsch. Rendering peroxides etc. safer for handling. 3685. Feb. 12.
McDavid, Williams, and Nobel's Explosives Co. Recovery and concentration of nitric acid. 3529. Feb. 11.
N. V. Stikstofbindingsindustrie Nederland. Manufacture of ammonia from products containing cyanides etc. 3763. Feb. 13. (Holland, 21.2.23.)
Soc. Anon. Comp. Gén. des Produits Chimiques de Louvres. Manufacture of salts of chrome. 4086. Feb. 16. (Fr., 16.2.23.)

Complete Specification Accepted

6597 (1923). Henkel et Cie., and Weber. Treating ammonium chloride lyes in iron vessels. (207,142.) Feb. 27.

VIII.—GLASS; CERAMICS

Applications

Cobb. Firebricks, crucibles, etc. 4537. Feb. 22.
Dynamidon-Werk Engelhorn u. Co., Engelhorn, and Schaefer. Manufacture of refractory compositions and bricks. 4388. Feb. 20. (Ger., 20.2.23.)
Priest. Refractory coverings for furnace shafts, flues, etc. 4631. Feb. 22.
Soc. d'Exploit. des Proc. Hidoux. Drying and pulverising clays etc. 4638. Feb. 23. (Fr., 24.2.23.)

Complete Specification Accepted

121 (1924). Riechers. Manufacture of raw plate glass. (209,417.) Feb. 27.

IX.—BUILDING MATERIALS

Applications

Crosland. 4055. *See* VII.
Décolland. Manufacture of aluminium cement in rotary furnaces. 3888. Feb. 14. (Fr., 14.2.23.)
Gayen. Manufacture of binding etc. substances for building materials. 3692. Feb. 12.
Huizer. Preservation and treatment of wood. 3867. Feb. 14.
Mackay. Bituminous emulsions. 3896. Feb. 14.
Marks (Polysius). 3534. *See* I.
Marks (Polysius). Burning raw cement sludge. 3535. Feb. 11.
Marpillero. Construction materials. 3981. Feb. 15.
Montgomorie. Bituminous etc. emulsions. 4358. Feb. 20.
N. V. Bataafsche Petroleum Maatsch. Manufacture of emulsions of asphalt etc. 3781. Feb. 13. (Holland, 30.10.23.) Feb. 13.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY

Applications

Borchers and Stimson. Purification of alloys containing iron and molybdenum, uranium, etc. 3622 and 4570. Feb. 12 and 22.
Evans. Recovery of zinc and copper from alloys. 4553. Feb. 22.
Fischer. Manufacture of ductile metals. 4279. Feb. 19.
Leyser and Nathansohn. Extraction of roasted zinciferous ores etc. 4190. Feb. 18.
Mackay. Electrochemical treatment of copper ores. 3792. Feb. 13.
Nathansohn. Dechlorination of lead products. 4314. Feb. 19. (Ger., 3.10.23.)
Rein. Cupola furnaces. 3841. Feb. 14.
Riemsdijk. Production of refined steel and alloys from titaniferous ironsand. 4428. Feb. 21.
Skappel. Recovery of metals from their compounds. 4518. Feb. 21. (Norway, 26.2.23.)
Stehli. 3670. *See* I.

Complete Specifications Accepted

22,454 (1922). Rosenhain and Grogan. Improving commercial aluminium. (211,027.) Feb. 27.
27,458 (1922). Hennes. Preparation of ores for leaching-process. (210,824.) Feb. 20.
30,562 (1922). Gronqvist. Cementation of iron and steel. (210,870.) Feb. 20.
31,052 (1922). Hamilton and Evans. Manufacture of iron and steel alloys. (211,210.) Feb. 27.
31,127 (1922). Diehl. Preparation and smelting of ores, roaster-residues, slags, etc. (211,215.) Feb. 27.
5719 (1923). Bardt. Precipitating or recovering metals from solutions. (211,005.) Feb. 20.
11,219 (1923). Akt. Ferrolegeringar. Heating metals or alloys in an electric furnace. (211,039.) Feb. 20.
11,616 (1923). Goldschmidt A.-G., Schertel, and Lüty. Refining tin. (196,938.) Feb. 27.
18,660 (1923). Siemens u. Halske A.-G. Lead alloys. (201,176.) Feb. 27.

XI.—ELECTRO-CHEMISTRY

Applications

Croucher and others. 3558. *See* XIX.
Dragonetti. Selenium cells. 3551. Feb. 11. (Ital., 12.2.23.)
Mackay. 3792. *See* X.

Complete Specifications Accepted

32,373 (1922). Rutter. Galvanic batteries or electric accumulators. (211,255.) Feb. 27.
11,219 (1923). Akt. Ferrolegeringar. *See* X.

XII.—FATS; OILS; WAXES

Applications

Holton. Detergent. 4426. Feb. 21.
Kammermann. Extraction of oil from vegetable substances. 4603. Feb. 22. (Belg., 21.1.24.)
Wilhelm. Extraction etc. of fatty acids etc. from oils etc. 3619. Feb. 12. (Ger., 24.12.23.)

Complete Specification Accepted

34,884 (1922). Petroff. Manufacture of detergent compositions. (211,294.) Feb. 27.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS

Applications

Brown. Simultaneous production of iron-oxide pigment and hydrochloric acid. 4175. Feb. 18.
K. D. P. Co. Manufacture of vegetable resins. 4069. Feb. 16. (Ger., 17.7.23.)
Semenza, Semenza, and Welch. Red lead paint. 3550. Feb. 11.

Complete Specification Accepted

31,248 (1922). Goldschmidt A.-G. Production of amorphous, finely subdivided litharge. (189,132.) Feb. 27.

XIV.—INDIA-RUBBER; GUTTA-PERCHA

Applications

K.D.P. Co. Manufacture of caoutchouc etc. 3574-5. Feb. 11. (Ger., 5 and 20.4.23.)

Naugatuck Chemical Co. Compounding rubber etc. 3865. Feb. 14. (U.S., 13.7.23.)

Peachey Process Co., and Peachey. Vulcanisation of rubber. 4658. Feb. 23.

Complete Specification Accepted

28,139 (1922). Russell and Broomfield. Waterproofing by the use of rubber latex. (211,188.) Feb. 27.

XV.—LEATHER; BONE; HORN; GLUE

Applications

Nelson, Dale, and Co. Manufacture of thin sheets of gelatin. 4183. Feb. 18. (Sweden, 3.5.23.)

Schottler, and Turner Tanning Machine Co. Machines for treating hides etc. 3842. Feb. 14.

Complete Specification Accepted

2282 (1923). Marris, and Walker and Sons. Treatment of spent tan, spent dyewoods, straw, and like inert vegetable matter. (211,322.) Feb. 27.

XVI.—SOILS; FERTILISERS

Applications

Carpmael (Chem. Fabr. auf Aktien, vorm. E. Schering). Means for protecting plants and animals against insects etc. 4195. Feb. 18.

Pease. Fertilisers. 4420. Feb. 20.

Redfern (Scheel). Fertilisers. 3564. Feb. 11.

XIX.—FOODS; WATER PURIFICATION; SANITATION

Applications

Carpmael. 4195. *See* XVI.

Croucher, Gush, and Gush. Electrolytic systems for treating water. 3558. Feb. 11.

Milkal, Ltd., and Sierra. Apparatus for making milk etc. powder. 3864. Feb. 14.

Quaker Oats Co. Treatment of seeds etc. with furfural. 3538. Feb. 11. (U.S., 5.7.23.)

Soc. Anon. des Rizières Françaises. Amylaceous flours. 4051. Feb. 16. (Ger., 19.2.23.)

Complete Specifications Accepted

4339 (1923). Lasson, and United Water Softeners, Ltd. Manufacture of water-softening materials. (211,340.) Feb. 27.

8851 (1923). Otteson. Preservation of food substances by cooling. (211,032.) Feb. 20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS

Applications

University of Toronto. Manufacture of anti-diabetic products. 4252. Feb. 19. (U.S., 2.3.23.)

Wacker Ges. f. Elektrochem. Industrie. Manufacture of acetic anhydride. 3663. Feb. 12. (Ger., 12.2.23.)

Complete Specifications Accepted

22,006 (1922). Imray (Meister, Lucius, u. Brüning). Manufacture of amidos of alkylated acids. (210,809.) Feb. 20.

32,095 (1922). Nobel Industries, Ltd. (Du Pont de Nemours and Co.). Production of urea derivatives. (211,245.) Feb. 27.

24,307 (1923). Meister, Lucius, u. Brüning. Manufacture of diaminodiaryldialkylmethanes. (204,722.) Feb. 20.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES

Applications

Roemmel. Photography. 4540. Feb. 22.

Soc. du Film K.D.B. Manufacture of photographic film. 3780. Feb. 13. (Fr., 16.2.23.)

Complete Specification Accepted

30,451 (1922). Sokal (Kalle u. Co.). Light-sensitive film or layer. (210,862.) Feb. 20.

XXII.—EXPLOSIVES; MATCHES

Complete Specification Accepted

21,946 (1922). Du Pont de Nemours and Co. High explosives. (184,487.) Feb. 20.

XXIII.—ANALYSIS

Complete Specifications Accepted

32,136 (1922). Woodroffe, and Scott, Ltd. Apparatus for determining the volumetric proportion of a gas or gases in gaseous mixtures. (211,240.) Feb. 27.

446 (1923). Simmance. Gas calorimeters. (210,950.) Feb. 20.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—

Baltic States: Tinplate, galvanised sheets, steel (230); *Brazil*: Iron tubes (852/22/F.G./E.C./2); *British India*: Iron and steel (the Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *Chile*: Steel, copper, iron, bronze, copper, soap, tin, oil, turpentine, paint, varnish, calcium carbide (9388/F.L./G.C.); *Cuba*: Tinplate, aluminium foil (245); Hardware, paper, heavy chemicals (246); *Finland*: Tinplate, galvanised sheets, steel (230); *Latvia*: Lubricating oil (8842/F.R./C.C./2); *Netherlands*: Leather cloth (233); Silk (234); Brass tubes (235); *New Zealand*: Builders' hardware, wall-paper (226); *Poland*: Tinplate, steel (230); *South Africa*: Iron pipes (13,211/E.D./E.C./2); *Spain*: Chemicals (238); *Switzerland*: Steel (239); *United Kingdom*: Lead-covered cable, zinc, copper, bronze, brass, steel (the Controller, Post Office Stores Department, Studd Street Depot, Islington, N. 1); *United States*: Heavy chemicals (21,940/F.W./C.C./2).

Census of Production for 1924

A census of production in Great Britain during 1924 is to be taken by the Board of Trade in 1925, and schedules will be issued later to all persons and firms who will be required to furnish information. The inquiry will cover not only manufactures, but also agriculture, fishery, mining and building, but, whereas the 1907 census included all undertakings, it is under consideration whether only undertakings employing more than 5 persons (including the employer) will be included. The examination of the second census, in 1912, was interrupted by the war, and when peace came the returns could not be amended or completed. Now that trade is becoming more normal, the need is felt for this periodical review of the facts of industry, so as to provide a sound basis on which to build a reliable estimate of the national income.—(*Bd. of Tr. J.*, *Feb.* 28, 1924.)

JOURNAL OF THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, MARCH 14, 1924 No. 11

EDITORIAL

THERE comes a period in life, and we are rapidly attaining to it, when leisure and god-like indolence are much desired. An arm-chair before a fire or an aimless stroll through a small garden are the due reward of earlier years of work and study. The activity of younger people is continually postponing our enjoyment of what we rightly consider our due. Our juvenile friend Mr. Woolcock urges us not only to arrange a set of pamphlets which will explain to the visitors to the Wembley Exhibition the importance of chemistry to the nation, but by specious eloquence he has deluded us into writing one of them in what he calls our spare time. In vain have we pointed out to him that quiet meditation and a contemplative mind are necessary for the task; his answer reminded us of the reply received by an Irish king who wrote to a subordinate chieftain, "Pay me the tribute thou owest, or else ——." The chieftain replied, "I owe no tribute, and if I did ——." At any rate, indefinite as were Mr. Woolcock's observations, we were left believing that unless the pamphlet were ready within a week something dire and terrible would befal. To expound the achievements of chemistry to the average visitor to an Exhibition is a vague task; how can we fit our Muse to the powdered flapper, the long-handed miller, the long-haired musician or the pale young curate? When we are lying awake with a dismal headache and repose is tabooed by anxiety, we have to think out some scheme for explaining Bohr's views on spectra or the constitution of Congo Red to a ravenous horde who all got on board at Sloane Square and South Kensington stations.

* * *

We have other grievances. Our youthful President, whose activity we envy and covet, in spite of any number of Commandments, has conceived the erroneous idea that it is time something was actually done about a Chemistry House. Writing about it and talking about it would have sufficed for most people, but like Oliver Twist he asks for more. We were content to have the idea simmering in our minds, but here comes Dr. Armstrong and stirs it round and round and round until he can sniff at the boiling broth. More conferences are to be held, sites are to be inspected, estimates of expenditure are to be considered and calculations about rents, rates and repairs, the three R's which play such an important part in a modern budget. "Give us work or we perish," say some. "Give us nothing to do or we perish," said our Cubian allies. Sometimes we think like Mr. Dooley that we are a bit Cubian ourselves. Well, well, the days are already getting longer, the children will wake earlier and the best way to lengthen your days is to add a piece on at each end. If Dr. Armstrong is succeeded in his Presidency by a man of ripe years—there is a retired Professor at Cambridge who would satisfy us—we shall have a restful time after next July. We can perhaps hold out till then and look forward to a really slothful existence. Even as we write some correspondent puts forward a desire for a universal language. We are in no frame of mind to undertake such a task. Universal quiet will be good enough for us. Every month we receive a chemical journal written in Polish. It gives us less trouble than any other publication which is sent to us. How rapidly and with how little fatigue we skim the pages after a satisfying meal and in a room religiously kept quiet for half an hour on a Sunday afternoon. Hail, Poland!

* * *

It gives us great satisfaction to announce that His Majesty the King has been graciously pleased to extend his patronage to the Annual Meeting of the Society to be held this year in Liverpool. We congratulate the Liverpool Section on this fresh token of the King's appreciation of the Society's work and are confident that this distinction will be greatly valued by the citizens of Liverpool, and by the members of the Society. Formerly, Kings were chosen for their physical strength, or if they were not chosen, they imposed their rule on the community if they were more skilled in the use of the sword and the battle-axe than their competitors. In these modern days the success of a King is judged by his unceasing devotion to the interests of his subjects and our present monarch has been conspicuous for a high standard of duty in all those social and other matters in which his subjects are concerned.

SOME PAGES FROM THE STORY OF INDIGO*

By W. A. DAVIS, B.Sc., A.C.G.I.

In the short time at my disposal I shall be able to turn only a few pages of the "Story of Indigo." This story, like that of linen, with which indigo has always been closely associated, begins in the very earliest periods of man's history. Long before man was able to clothe himself in "purple and fine linen," tradition has it that he ornamented his skin with the extract of woad, one of the plants yielding indigo. Both linen and indigo had their origin in the early civilization of the East and it is interesting that both depend on very similar complex bacterial changes for their production.

The linen fibre and the indigo used to dye it are both of plant origin and both are obtained by leaving the stems of a plant in contact with water, when certain peculiar changes set in spontaneously which in the one case set free the valuable linen fibre and in the other the far more precious blue dye indigo. In the warm climates of the older civilizations—China, Egypt and India—the conditions for the growth and fermentation of the flax and indigo plant were ideal, and until very recently the preparation of both linen and indigo was carried out in almost precisely the same way as was practised in the days of the Pharaohs.

The Importance of the Indigo Industry

The importance of indigo may be realised from the fact that not only was it the most widely used and valuable dye during countless generations of the past, but even at the present day it is by far the most important dyestuff.

Neglecting the smaller indigo-producing countries such as Central America, Brazil, the Philippines, the value of the total world-market for indigo under pre-war conditions considerably exceeded 5 millions sterling. This value falls not far short of that of all *other artificial organic dyes put together* as can be seen from the following table showing the German exports of dyes before the war. It must be remembered that Germany then supplied six-sevenths of the world's requirements of artificial organic dyes.

Growth of the Synthetic Indigotin Industry

This is not the occasion to describe in detail the history of one of the greatest and most [illegible]inating achievements of modern chemistry—th[illegible]cation of what only 40 years ago was regard[illegible]ct as a dream—the manufacture on an e[illegible] scale from coal tar of indigotin, the chief [illegible]t of the valuable natural dyestuff indigo. [illegible]gress of modern chemistry indigo has played a supreme part. It was from natural indigo that in 1841 Fritsche obtained aniline—the parent substance of the so called "aniline dyes." In fact the very name *aniline* is derived from the Indian name for indigo—*nil*, which passed into Europe in the Portugese (or Arabic) form *Anil*.† The apparent close relationship of indigo and aniline very early suggested the possibility of preparing indigo synthetically from coal tar, and it was while working with this end in view that W. H. Perkin in 1856 studied the behaviour of aniline with arsenic acid, which led to the discovery of the first aniline dye mauve. Then came the discovery of the diazo reaction by Peter Griess and the wonderful development of the azo-dye industry, which culminated in the synthesis of indigotin itself. The cycle was complete.

So long ago as 1870, indigotin identical with the blue dyeing principle of natural indigo, was synthesised by Engler and Emmerling, but nearly 30 years had to elapse before the manufacture of synthetic indigotin became a commercial success. During this period, in German universities and German works, the problem was pursued persistently and without rest, "Ohne Hast, ohne Rast." The prize was one well worth winning—the capture of an industry representing at that time, when the aniline dye industry was of smaller dimensions than at present, a money value far exceeding that of all other dyes put together. From 1865 to 1880, A. von Baeyer with his numerous pupils worked on the problem and a complete synthesis of indigotin in 1880—1882 firmly established the structure of the indigotin molecule.

Baeyer's processes were patented and purchased by the Badische Company for £20,000 and were worked on a large scale. It was soon found, however, that these processes were an economic impossibility because of the shortage of the world's supply of toluene—the substance which during the great war was used in enormous quantities for the manufacture of the most powerful high explosive, trinitrotoluene (TNT). In spite of the very big increase of production of crude tar which followed the introduction of the modern metallurgical coke-furnaces—especially in Germany—the amount of toluene obtainable from crude benzene would only be enough to produce indigotin sufficient to cover one-fifth or one-sixth of the whole consumption. An increase of the production of crude benzene for the purpose of obtaining more toluene would have led to over-production of unusable (at that period) benzene and hence would have increased the price of toluene and finally, that of synthetic indigotin.

Although the Badische Company had incurred heavy losses by working Baeyer's processes, they did not hesitate to purchase in 1890 the patent of K. Heumann, who had introduced a process starting with naphthalene. This was the turning point of the indigotin industry. Economically, his process was far preferable to the synthesis from toluene.

* A lecture delivered to the chemists of [illegible]. Lever Bros., Ltd., Port Sunlight, on Jan. 28, 1924.

† "*Nil*" (derived from Sanscrit) is the ordinary Hindustani word for "blue." Indigo is thus *the* "blue" dye. "Indigo" is derived from the Greek "Indikon" (Lat. Indicum), the Indian (dye). The word "nil" is also seen in the Egyptian "Nile"—the blue river.

Quite 50,000 tons of naphthalene were produced annually in the distillation of tar and at this time only about 15,000 tons had been utilised—the rest was a "waste product."

But even working this process the output of synthetic indigotin was not much increased until 1897—that is seven years later, as is shown by the following data:—

Table II

	1880	1890	1895	1900
Export of synthetic indigotin from Germany in tons	497	733	653	1873

The obstacle was the fact that the first stage of the process, the oxidation of naphthalene to phthalic anhydride by heating with sulphuric acid, gave a very poor yield. In 1897 a fortunate "accident" made the process ultimately a brilliant commercial success. From the breaking of a thermometer in the vat in which naphthalene was being heated with sulphuric acid and the keen observation of its effect by the chemist in charge dates the downfall of the natural indigo industry. It was noticed that the small quantity of mercury from the thermometer which fell into the sulphuric acid, greatly accelerated the action and that a nearly theoretical yield of phthalic anhydride was obtained. Instead of the action being very prolonged and accompanied by many destructive changes, it was complete in a few hours and its rapidity made it *possible to collect and use over again* the large quantities of sulphur dioxide evolved. This led to the development in Germany of the so-called "contact" process of manufacture of sulphuric acid—a process by the way (like the aniline dye industry) invented and worked in England so far back as 1875 by Rudolph Messel, of Messrs Spencer, Chapman and Messel, though only developed on a very large scale many years later in Germany. So that the fortunate "accident" already alluded to not only made synthetic indigotin an economic possibility but also gave to Germany what is now one of its most important industries. The sulphur dioxide liberated during the action of sulphuric acid on naphthalene was reconverted into sulphuric acid by the contact process, so that the process became a continuous one in which little or nothing was wasted.

The necessity of recovering large quantities of sulphur dioxide thus led the Badische Company entirely to reconstruct its system of manufacturing sulphuric acid. It is difficult fully to estimate the *indirect* influence the synthetic indigotin process has had on other industries (such as other branches of the dyeing industry, the artificial fertiliser industry—sulphate of ammonia, superphosphate), by facilitating and cheapening the production of sulphuric acid. That the processes and plant introduced at this time were an important factor in Germany's military strength is abundantly clear. It was, too, no doubt, the lying idle of the liquid chlorine plant which had formerly been used to supply chlorine in very large quantities for a later stage of the indigotin synthesis (the manufacture of monochloracetic acid) which gave the opportunity for the use of chlorine in the early gas attacks which so nearly changed the whole course of the war at Ypres. The magnitude of the change introduced at this time into German chemical industry by the B.A.S.F. can be gauged by a few data.

In 1888 the Badische produced 18,000 tons of sulphuric acid catalytically and in 1900, 160,000 tons. In 1901 the quantity of sulphur dioxide recovered by this process from the manufacture of phthalic anhydride alone was about 40,000 tons. The first artificial indigotin plant was erected by the Badische at the cost of £480,000. In 1900 two competitors appeared, viz., Meister, Lucius, und Brüning of Höchst-am-Main and Messrs. Geigy of Basle, the latter working Sandmeyer's process. The considerable fall in price of synthetic indigotin which followed this acute competition led to Messrs. Geigy abandoning the field and to the amalgamation of the Badische and Meister Lucius interests with a capital of £1,200,000. Before long this partnership was, however, dissolved. In 1910 the Rathjen Company of Hamburg with a capital of £280,000 started making indigotin, using an improved form of Sandmeyer's process, and von Heyden of Dresden, one of the largest chemical works of Germany, also took up the manufacture, working the so-called phenylglycine process. In Switzerland the Society of Chemical Industry in Basle began making indigotin in 1911—1912.

Although the introduction of the catalytic oxidation of naphthalene and the contact process of manufacturing sulphuric acid were great steps in advance they did not enable synthetic indigotin easily to compete with the natural dye, which as I shall show has certain very real advantages. There is, indeed, good ground to believe that synthetic indigotin was sold at a loss for a long period in the endeavour to capture the market and that for this purpose large subsidies were given by the German Government. It should be emphasised here that the ultimate process adopted by the Badische Company involved the use of information derived neither from Von Baeyer, nor from the works laboratories, but from the Zürich professor Heumann, who had attacked the subject independently and devised methods that were far simpler than any of those discovered by the prime workers. The Heumann process involved fusion with caustic potash in the final stage. In this fusion water was a product; this had an adverse influence on the interaction, and it was necessary in order to maintain control of the operation to carry it out with only small quantities of material. As an economic process the method was therefore unsatisfactory. Success was only made possible by the perseverance and technical skill displayed by the German manufacturers and by their obstinate determination to carry the day against Indian indigo. But this struggle could not well have been successful in the end had not at this time an invention been perfected by a firm having nothing to do with colour making. The invention was that of a process of making sodamide, $NaNH_2$, from metallic sodium and ammonia. Sodamide, it was found, could be used with great advantage instead of caustic soda in the indigotin melt; in place of water it gave ammonia which had no deleterious effect and moreover could be easily recovered and used over and over again. From this moment the process became an economic success.

Natural Indigo

In synthetic indigotin we have an industry in which the resources of modern science have been utilised to the uttermost—in which all that chemical and engineering skill can offer has been called in aid—in the preparation of natural indigo we have the exact opposite—an industry in which the processes were, until quite recently, of a very primitive character, but very much different in fact from those practised in ancient Egypt 3000 years B.C. The plant is cut in the field in the early morning, carted to the indigo factory (often 2 or 3 hours' journey away) in bullock carts and loaded into large cement-lined vats. After loading the plant is "watered"—that is the vats are filled with water warmed if necessary to a temperature of 90° F. The watering takes about half an hour to an hour. The plant is kept down and held in position by means of cross beams fastened across the tops of the vats. The plant is then left to "steep" in the water during about 12 hours; after about 4 hours a bacterial fermentation sets in, the effect of which is that the parent substance of the dye, the so-called *indican*, originally present in the leaves of the plant, passes into solution. The materials originally fermented in the solution consist of protein and carbohydrate material exuded from the cut stems and the gas liberated by the fermentation consists mainly of nitrogen and hydrogen in the early stages. Gradually the process changes, carbon dioxide is evolved in increasing proportion and the vat liquor becomes slightly acid.

Indigo is not originally present in the plant as the blue dye, but as a colourless, beautifully crystalline glucoside, indican, which itself is a compound of the sugar dextrose with *indoxyl*. During the bacterial fermentation as fast as the parent substance indican passes from the leaves into solution, it is hydrolysed by bacteria to *indoxyl*, itself a colourless substance. When the fermentation is complete, that is after 12 hours, a slightly yellow solution, without any blue colour, is obtained. From this process the dye is obtained by the treatment known as "beating." To carry out the "beating," the liquor obtained from the steeping, is run into large vats at a lower level and then thrown up into the air by means of a large paddle-wheel (beating wheel) as a fine spray. In this way the colourless *soluble* substance, indoxyl, is oxidised by atmospheric oxygen to the blue *insoluble* dye indigotin. After about 1½ hours the beating is ended, and the wheel is then stopped and the indigo allowed to settle out during about 4 hours, as a fine blue mud. With a good fermentation the settling is nearly perfect, but with a bad fermentation it is very incomplete and 20 to 30 per cent. of the indigo may be lost in this way. After settling, the supernatant liquid is carefully run off (an operation necessitating skill) by special valves and the thick blue mud remaining, transferred to a boiling tank where water containing a small amount of dilute sulphuric acid is added and the mixture raised to the boil by live steam. This treatment dissolves out a considerable proportion of the impurities (the so-called indigo-gluten) and arrests fermentation. After the boiling the indigo is again allowed to settle out and as much as possible of the clear liquor run off. The residue is then transferred to the "filtering tables,"—large frames across which cotton cloths are stretched—and drained as completely as possible. The residual thick paste is then pressed between cloths in large wooden boxes, slabs of indigo 3 in. thick being obtained. The slabs are then cut up, by wire cutters, into 3 in. cubes, and these are left to dry slowly in the air, until the cakes contain only about 6 per cent. of moisture. This drying usually takes a month to 6 weeks. The small 3 in. cubes are finally brushed and polished and packed into large wooden chests, holding 300 lbs. and sent down to the Calcutta market.

Decline of the Natural Indigo Industry

Up to 1897 the increase in prosperity of the Indian indigo industry during a century had been phenomenal But the introduction of the Badische processes brought about a rapid and steady decline, until in 1914 just before the war, only about 1/20th of the quantity made in 1896, the high-level mark of natural indigo, was being manufactured.

Table III

Exports of indigo from India

Year		Cwt.		Value Rs.
1894-5	..	166,308	..	4,74,59,153
1895-6	..	187,337	..	5,35,45,112
1899-1900	..	85,460	..	2,08,78,848
From 1897 to 1906 there was a steady decline.				
1906-07	..	35,102	..	70,04,773
1911-12	..	19,155	..	37,58,025
1912-13	..	11,857	..	22,01,325
1913-14	..	10,939	..	21,29,070

In 1895, 1,688,042 acres were under indigo; in 1914, the area had fallen to about 200,000 acres. In 1880 excluding the agricultural labourers, who were very numerous, 360,000 persons were employed in the indigo industry. In 1911, the number had fallen to 30,795.

(*To be continued*)

Mons. E. Cuvelette, vice-president of the Etablissements Kuhlmann, has been promoted Commander of the Legion of Honour. Messieurs E. Hures, of the Société de Carbonisation and de Distillation des Combustibles; J. Naud, president of the Denain and Anzin Iron and Steel Works; J. F. Vogt, director of the Ste. Thérése Potash Mines; E. Vielhomme, [illegible]-president of the Cie. Alais Froges et Camargne, [illegible] M. Dumuis, director of the Firminy Iron and [illegible], have been appointed chevaliers of the L[illegible] of Honour. Prof. Joubin, director of the [illegible] and Technical Office of Maritime Fisheries, [illegible] appointed Commander, and Mons. E. Roux, [illegible] of the Sanitary and Scientific Services of the [illegible]istry of Agriculture, has been nominated Grand [illegible] of the Legion of Honour.

THE "PEEBLES" PORTABLE SAND WASHER

(From a Correspondent)

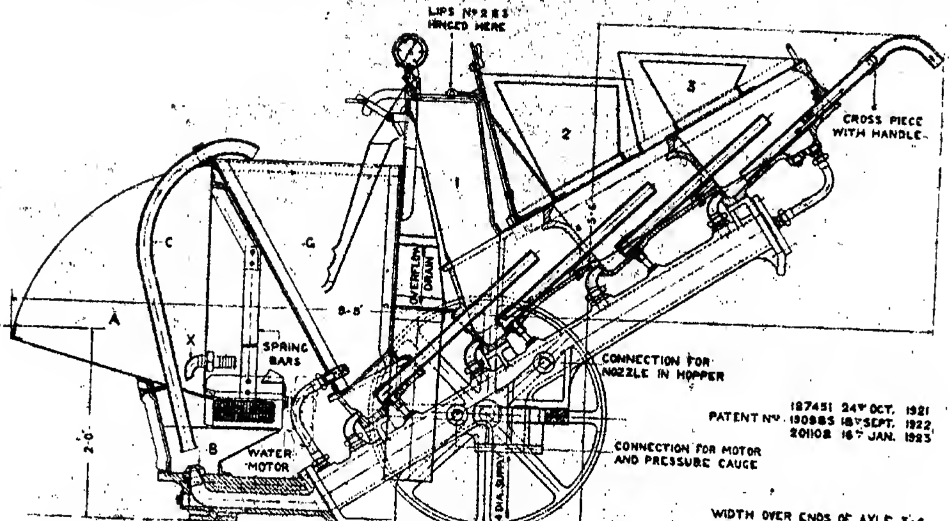
One of the most unsatisfactory operations connected with the use of sand filter-beds for either portable or technical water supply is the washing and cleaning of the dirty sand. This has hitherto generally been carried out by laborious hand methods in large tanks, using a high-pressure water jet, say at 60-80 lb.

Some two years ago Messrs. Glenfield and Kennedy, Ltd., of Kilmarnock, introduced the "Peebles" patent sand washer for carrying out automatically and continuously the washing of dirty sand, using no other power than a very low pressure (say 4-5 lb.) water jet. This machine, which is extremely compact, being contained in a wrought iron tank, 6 ft × 4 ft. × 4 ft., has effected what may be described as a revolution in the washing of sand

There has now been introduced a portable machine on the same general lines, which can be wheeled about by hand from one filter bed to another, so that the sand can be washed on the spot. The apparatus merely requires to be coupled up by flexible connexions to the low-pressure clean water supply, and to a discharge pipe for the dirty water; the sand is thrown into the hopper, the clean sand being discharged continuously from the other end of the machine.

The apparatus, of a total weight of 13 cwt., is extremely neat and easy to handle, well-balanced on two large flat type cast-iron wheels, and has the over-all length of 9 ft., width 5 ft. 4 in., and height, 5 ft. The output depends to some extent on the water pressure available, but at 5 lb. the figure is 4·15 tons (98 cb. ft.) of sand per hour, the time required to wash 1 ton being 14½ minutes, that is about six times the speed of hand methods. Even at only 3 lb. water pressure the figure is 2½ tons (60 cb. ft.) of sand per hour, or 23½ minutes for 1 ton. Further, the machine, although light, is extremely strong, there is practically nothing to get out of order, the wear and tear is infinitesimal, and unskilled labour can be used, all that is being required to shovel the dirty sand into the hopper, whilst the cleaning is much more effective than by the ordinary methods.

The machine is operated by a series of water jets, the total consumption of water at 5 lb. pressure being about 8000 gals. per hour. It consists essentially of a series of 4 small washing chambers one behind the other on an inclined plane connected at the bottom by a cast-iron feeder pipe, the whole resting on a steel axle between the wheels. The sand falls from the hopper through an oscillating strainer,



The "Peebles" Portable Sand Washer

operated by a small water motor, so as to separate all pebbles and similar large particles. The filtered sand then falls into a chamber at the bottom of which is a jet of water which forces the sand upwards and mixes it in the water. The principle depends on the fact that the dirt and impurities are lighter than the sand, and are washed out in a stream of water over a weir to a discharge, whilst only the heavier sand is carried over into a second chamber. Here it meets a second water jet, where the process is repeated, the sand being propelled continuously through the four chambers in succession in this way by a series of clean water jets, thus repeatedly washing and mixing the sand, and separating the lighter dirt and impurities by gravity, the purified sand being finally discharged from the machine in a continuous stream along with clean water. The cleaning action is also intensified by the repeated change of direction of the sand within the machine, and the consequent scrubbing action of each grain of sand on its neighbour, and altogether the whole device is ...

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL

The relationship existing between yields of tar and gas obtained by the distillation of coal, was the theme of the second of a series of Cantor Lectures delivered by Mr. E. V. Evans at the Royal Society of Arts on March 3. The dilution of a rich coal gas by the admixture of a small proportion of furnace gases under strict control was described and it was shown how the process enabled a gas of very uniform calorific value to be produced at the inlet to the gas holder. It is found to be more economical to reduce the calorific value of the gas to a desired standard in this way than to raise the temperature of the combustion chamber surrounding the retorts materially above 1300° C. The yield of gaseous therms is about the same whichever method be adopted, but the employment of higher temperatures results in a destruction of tar. The results of many investigations upon carbonisation recorded in technical literature show a lack of appreciation of the part played by tar by reason of the fact that attention has been focussed too closely upon the gaseous product.

When coal was carbonised at different rates in laboratory apparatus it was found that a very low rate of heating favoured the production of an increased yield of coke at the expense of the volatile matter. The greatest yield of volatile therms was obtained with the most rapid heating of the coal up to 1000° C. This condition also allowed of the production of a maximum yield of gas therms. With a decrease in the rate of heating the yield of gas therms fell and then rose slightly, the maximum yield of tar therms being obtained when the yield of gas reached the minimum. For the purpose of ascertaining whether a more careful method of carbonisation would still give a low yield of volatile therms, carbonisation was carried out in two stages, a temperature of 525° C. being taken as the first stage. The process proved to be less drastic in that an abnormally high yield of tar was obtained whilst the yield of gas therms was quite low. These phenomena are explained by supposing that when coal is very slowly distilled there occurs simultaneously a fractional distillation of the tar with the consequent formation of pitch. The tar obtained under these conditions is a limpid brown fluid containing little pitch and practically no free carbon. The gas obtained from rapid carbonisation is characterised by a high proportion of unsaturated hydrocarbons, a fact which points to the decomposition of primary tar. It is significant, however, that the therms lost from the tar were approximately recovered in the gas; thus further proof was obtained that the rapid heating of coal as in normal gasworks practice is not so wasteful of thermal energy as advocates of other methods of distillation have suggested. Very rapid carbonisation is a gas-producing process, slower and more careful distillation is a tar-conserving process, and exceedingly slow distillation a coke-conserving one.

The analyses of tar obtained from the carbonisation of Durham coal at different temperatures showed that there is a limit to the quantity of gas which may be produced from tar without producing such a degree of deterioration that the physical and chemical constitution of the residual tar is altered to an undesirable extent. At the higher temperatures naphthenes, paraffins and phenols are gradually replaced by pitch, and the free-carbon content of the pitch shows a very marked increase.

In order to illustrate the complexity of the chemistry of tar cracking the decomposition of cyclohexane by heat was considered in some detail. A novel feature of the lecture was the introduction of a cinematograph film in order to show the decomposition of cyclohexane to cyclohexene and *n*.hexylene, and the formation of lower olefines from the latter. The decomposition of cyclohexene to hexadiene and the mechanism of the reactions giving rise to the production of butadiene, acetylene and naphthalene were also illustrated in a manner calculated to make a special appeal to those responsible for the teaching of chemistry.

It was concluded that hydrocarbons of the cyclohexane and cyclohexene type are the main gas-yielding constituents of primary tar; they are probably selectively cracked during the carbonisation of coal, leaving a residue of secondary tar less suitable for further cracking. The gas obtained is rich in unsaturated compounds, and has a high calorific value. Higher aromatic compounds are formed by polymerisation and condensation of these unsaturated hydrocarbons. Direct hydrogenation with the formation of benzene and its homologues takes place to an extent insufficient to account for the quantity of these compounds found in high-temperature tar. The relative proportions in which the various decomposition products are produced was shown to be influenced by the temperature at which the cracking takes place. At higher temperatures the proportion of free carbon and gas increases whilst the liquid decomposition products become more aromatic in character.

In another series of experiments high and low-temperature tars were heated to various temperatures, the vapours being cracked in the presence of nitrogen or coal gas. Low temperature or primary tar gave a fair yield of gas at temperatures as low as 600° C., a large proportion of the tar being recovered as a liquid which may be regarded as secondary tar.

Directly a primary tar has been converted by cracking to a secondary tar, it should be removed from the retort as quickly as possible, as the compounds present in high-temperature tar having resulted from the decomposition of less stable bodies, are themselves comparatively stable. They decompose only at the highest temperature of carbonisation, mainly with the elimination of hydrogen, and the formation of compounds of increasing molecular complexity. A very limited yield of gaseous therms is obtained from such a secondary tar by the sacrifice at considerable loss of benzene and its homologues. The nature of the gas obtained during carbonisation is indicative of the nature of the reactions taking place in the retort. The greater the percentage of unsaturated hydrocarbons in the gas the greater the quantity of primary tar which has been decomposed, and a low proportion of these hydrocarbons may

indicate that the gas and tar have been subjected to too long an exposure to heated surfaces.

An analysis of the balance sheets of the London gas companies showed that it was economically sound for a gas undertaking to gasify as much tar as possible so long as working difficulties were not experienced in the retort house, and so long as the residual tar was not so degraded that its value per therm was reduced. In this connexion it was suggested that the free carbon content of the tar should not exceed 15 per cent. Microscope slides were exhibited in order to demonstrate a method of observing the free-carbon content of tar.

The tendency in recent years in the gas industry has been to charge greater weights of coal into retorts and to extend the period of carbonisation. This process conserves tar, and there comes a point at which it is desirable to increase the temperature of the setting so as to permit of the cracking of tar. The most recent tendency is thus to maintain the larger charges of coal and to reduce the period of carbonisation for the purpose of increasing the gaseous thermal yield. It was forecasted that there would arrive a limit at which retort house difficulties would arise due to the production of too viscous a tar, but where precisely was this transition point was unknown. Since the cracking of primary tar as it is produced is such a different process from the cracking of secondary tar in a heated chamber it was argued that the reduction of the free space in horizontal retorts and an increase in the rate of heat transmission within the mass of coal itself were matters demanding careful consideration.

ASBESTOS IN QUEBEC

The output of asbestos, chief of Quebec's mineral products, showed a considerable improvement during 1923, the production reaching the record amount of 205,000 tons, valued at \$7,500,000. In 1922 163,706 tons were produced valued at \$5,552,823. Whilst 1923 is the record year for production in the asbestos industry, it must be noted that when the previous high record was established in 1920 and 199,573 t. was marketed, the receipts from sales reached a total of \$14,792,201 or approximately twice the amount received for the tonnage sold during the year just closed.

An important industrial development in the Province of Quebec is the establishment of a plant for the manufacture of asbestos products. The undertaking is of special interest because it represents a new venture in the manufacture of asbestos products on a large scale in Canada. The plant is being erected at Asbestos, Quebec, where the asbestos is being mined. This will help materially in keeping down costs, since freight charges will be eliminated. The following articles will be produced: asbestos roofings, shingles, packings, building materials of all kinds, insulation, paper and mill board, brake linings and other products.

LOW TEMPERATURE CARBONISATION *

By A. McCULLOCH, A.M.C.T., A.I.C.

The low-temperature carbonisation of bituminous coal may be dealt with under three headings:—(1) The need for a solid *smokeless* fuel, suitable particularly for domestic purposes. (2) The difficulties encountered in producing such a fuel from bituminous coal, and (3) The progress which has, so far, been made in this direction, and the future of a low-temperature carbonisation industry.

The Need for Smokeless Fuel

Lord Macaulay relates that in the year 1307 an Englishman was executed for the burning of raw coal to the detriment of his fellow citizen's health, whilst in 1580 Queen Elizabeth prohibited the use of coal in London whilst Parliament was in session, " because the health of the knights of the shires might suffer during their abode in the Metropolis."

Since these early days we have become inured to the emission of smoke from countless domestic and industrial chimneys, but a consideration of the damage occasioned by such smoke is startling. It has been computed that the extra cost for fuel and materials for washing in Manchester alone, owing to the smoky atmosphere, is nearly £250,000 annually, whilst the extra labour entailed totals 668 years. The annual national " Black Smoke Tax " is approximately £40,000,000. E. D. Simon ("The Smokeless City," Longmans, Green and Co.) states that 75 per cent. of the damage caused by smoke to property and health is due to domestic smoke, and that improved plant and a general desire for fuel economy amongst power producers are responsible for the tendency for the disappearance of air pollution from industrial smoke to disappear. By carbonising coal at the temperature of about 600° C., as distinct from carbonisation at about 1000° C., as in the modern gasworks, it is possible to produce a coke suitable for domestic purposes. Such a coke whilst smokeless on combustion, ignites readily, and can be made sufficiently strong to withstand considerable handling and transport. To replace the 35 million tons of coal consumed annually for domestic purposes, it would be necessary to carbonise 54 million tons of coal at a low temperature, but the by-products recovered would be of the following dimensions:—

Light Spirit	121 million gallons.
Tar	972 " "
Ammonium sulphate ..	337,000 tons.

With some reservations, it can be said that the tar is of such a nature that it will find use as " fuel oil," whilst motor spirit can be manufactured from the light spirit obtained. The fertilising value of ammonium sulphate is well known. The national importance of such a low-temperature carbonisation system at once becomes apparent, and the question naturally arises, " What practical difficulties are encountered in carbonising bituminous coal at a low temperature, and what progress has been made in establishing a low-temperature carbonisation industry ? "

* Lecture before the Manchester College of Technology, Evening Students' Chemical Society, on January 22.

The Manufacture of Smokeless Fuel

Two main difficulties arise in the manufacture of low-temperature coke due to (*a*) the excessive swelling of certain types of bituminous coal on carbonisation at a low temperature, and (*b*) the low thermal conductivity of coal.

(*a*) Bituminous coal may be regarded broadly as consisting of a fusible portion and a non-fusible portion. The fusible portion appears to melt at temperatures of 350° C.—450° C., and acts in this condition as a binding or cementing agent for the non-fusible constituents. On the continued application of heat decomposition takes place, and the gases evolved "blow out" the pasty mass, causing the coal to swell. This swelling is excessive with certain bituminous coals, normally employed for the manufacture of metallurgical coke and as gas-coals, and measures must be taken in low-temperature carbonisation to modify the swelling and prevent the charge "sticking" in the retort. At higher temperatures, such as obtain in a gasworks retort, the coke subsequently shrinks, and this difficulty does not arise. Excessive swelling can be overcome by "blending," which consists in intimately mixing a strongly swelling coal with a non-swelling coal, or with a coke obtained from a previous carbonisation. Another method is that adopted in the Illingworth process. The fusible constituents of bituminous coal decompose over varying ranges of temperature. By a selective preheating a portion of the fusible constituents can be destroyed, and the swelling of the coal can be correspondingly modified. By blending and preheating the strength and nature of the coke can also be modified. In certain processes mechanical means are taken to overcome excessive swelling.

(*b*) In high-temperature carbonisation processes, the charge requires heating about eight hours before carbonisation is complete, owing to the low thermal conductivity of the coal. In low-temperature carbonisation processes, the temperature gradient is in comparison very low, and it has been found necessary to reduce the thickness of the coal charge to four inches, in order that the period of carbonisation shall not be excessive. Alternately, a gaseous heating medium such as superheated steam, coal gas, or producer gas may be employed, or the coal may be passed continuously through the retort during the carbonisation so that each piece of coal comes into intimate contact with the hot wall of the retort.

We may date the beginning of low-temperature carbonisation as a commercial venture from 1906, when Thomas Parker (who originated the term "coalite") patented plant in which the coal was carbonised at a low temperature, in layers of about four inches in thickness. From that date numerous patents have been taken out [illegible] many processes have been worked, although [illegible] has yet justified the high expectations entertain[illegible] the patentees. Definite progress has, howev[illegible] made in the manufacture of low-tempera[illegible]e, and remaining difficulties centre round the [illegible]mic utilisation of the by-products, rather than round the actual manufacture of a satisfactory smokeless domestic fuel. Three typical processes may be described.

(1) The "Coalite" Process (Low-Temperature Carbonisation, Ltd., Barnsley) is typical of processes in which the coal is stationary in the retort during carbonisation, the retort being heated externally. Blending of suitable coals is carried out in a washer of standard type, and after draining, the coal passes to charging bunkers situated over individual retorts. The distance from centre to centre of the retorts is 21 inches, the retorts being built in batteries. Each retort is provided with two manganese cast-iron plates, situated inside, and running the whole depth of the retort. Mechanism is provided whereby the plates can be brought closer to one another. The coal is charged into the free space between the plates and the sides of the retort, being supported on a bridge-piece placed below the plates. The distance between the plates and the sides of the retort is approximately four inches. When carbonisation is complete, the period of carbonisation per charge being eight hours, the plates are brought nearer together, the bridge-piece is rotated and the mass of coalite falls into a specially-designed cooling chamber, situated below the retort. Here it is cooled, the chambers being water-jacketed, the steam generated being used in auxiliary processes. The "Coalite" is obtained in large cakes requiring breaking and sizing prior to sale. It is sufficiently hard to withstand considerable handling and transport and burns readily, giving a pleasant, smokeless fire.

(2) The "Carbocoal" or "Smith" process, of American origin, utilises an externally-heated retort, through which the coal is mechanically propelled during carbonisation. The retort is of an inverted "heart" shape, and is provided with two internal shafts fitted alternately with paddles. The shafts revolve in the retort, and the coal, fed into the retort by a screw conveyer from a charging bunker, is passed through the retort by the paddles. Carbonisation lasts from two to three hours, and the coked residue is discharged from the retort in a pulverulent condition, through a water seal. This coked residue is the true low-temperature product. In order, however, to fit it for sale, it is briquetted, after mixing with pitch, in "roll" presses, and the "ovoid" briquettes so obtained are carbonised at a high temperature giving a product known as "Carbocoal." The "carbocoal" briquettes are exceptionally hard and compact, but are more suitable for use in anthracite stoves and as boiler fuel, than as a smokeless domestic fuel for use in the ordinary grate.

(3) In the Pure Coal Briquette Process the sensible heat of a stream of superheated coal-gas is employed for carbonisation, an internally-heated retort being employed. This process represents the most recent development in low-temperature carbonisation, in so far as the properties of the fuel obtained are dependent upon a preliminary treatment prior to carbonisation, and upon the temperature conditions during carbonisation. The coal, cleaned by passage through a battery of "froth flotation" cells, and dryers of the "static" type, is pulverised to a fineness comparable with that required for powdered fuel for boiler furnaces and cement kilns.

The finely-divided coal is then briquetted under a pressure of about ten tons per sq. in., no pitch binder

being added. Carbonisation of these briquettes under varying temperature conditions yields a fuel suitable either for domestic purposes, boiler fuel, or metallurgical coke, for which remarkable claims are made with regard to consumption per ton of pig iron produced in the blast furnace. Retorts have been designed to carbonise 500 tons of briquettes per retort per 24 hours, and it is hoped that by utilising retorts of such large capacity and by the system of internal heating adopted, the low costs of carbonisation may offset the cost of cleaning, drying, pulverising, and briquetting. The process has yet to be tried out on a large-scale plant, but experimental plant has given encouraging results over a considerable period. The further development of the process will be viewed with much interest by all concerned in fuel economy, marking as it does an entirely new departure in carbonisation processes for the production of smokeless fuel.

The success or failure of many industrial processes centres in the value of the by-products as distinct from the main product. Besides the 15 cwts. of low-temperature coke obtained from every ton of coal carbonised there is obtained :—

(1) 20 to 25 gallons of tar, which is characterised by its liquid nature, its low free carbon content (3 per cent.), and a composition approximating to :—
  (a) 50 to 80 per cent. of hydrocarbons, mainly paraffin, naphthene, and unsaturated hydrocarbons, whilst benzene, toluene and the homologues are either entirely absent or present only in small quantities.
  (b) 20 to 50 per cent. of tar acids—phenol being present only in small quantities, cresols, and xylenols to the extent of 2 to 4 per cent. of the tar, whilst the remainder are mainly higher phenols which are viscous oils or resinous solids.
  (c) Small quantities of nitrogenous and sulphur bodies.
(2) From processes employing externally-heated retorts 3000 to 3500 cb. ft. of gas of 800 to 1000 B.Th.U. per cb. ft. From many processes employing internally-heated retorts 20,000 to 25,000 cb. ft. of gas of approximately 230 B.Th.U. per cb. ft.
(3) Varying yields of ammonium sulphate which may be said to be from 10 to 25 lb.

The processes producing large volumes of low-grade gas (230 B.T.U. per cb. ft.) must find application in industries in which such gas can be economically utilised, as for example the steel industry, whilst the small volumes of high-grade gas (800 to 1000 B.T.U. per cb. ft.) from other processes may find application as an enriching agent for town's gas produced by gasworks processes in which steaming is employed.

The greatest difficulty centres in the economical utilisation of the low-temperature tar. Our knowledge of its composition is far from complete, and although with some reservations with regard to viscosity and flash point it can be employed as fuel oil, we have yet to discover a scheme for its utilisation which is comparable with that in existence for the utilisation of high-temperature tar.

Mar. 28. SOCIETY OF CHEMICAL INDUSTRY, *South Wales Section*, the Technical College, Mount Pleasant, Swansea, at 7.15 p.m. Annual Meeting, addressed by Capt. H. Vivian.

Mar. 28. THE MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, *Chemical Section*, at 7 p.m.

Mar. 28. SOCIETY OF CHEMICAL INDUSTRY, *Glasgow Section*, Engineers' and Shipbuilders' Institute, 39, Elmbank Crescent, at 7.15 p.m. "The Influence on Chemistry of the Recent Knowledge Gained of Atomic Structure," by J. A. Cranston, D.Sc.

Mar. 31. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2 (Cobb Lecture), at 8 p.m. "Certain Fundamental Problems in Photography" (Lecture II.), by Dr. T. Slater Price.

The meeting of the South Wales Section of the Society with the Faraday Society, announced in our last issue for March 14, has been postponed until October next.

The Ordinary Meeting of the Faraday Society that was to be held on March 17 will not take place, but an Ordinary Meeting will be held on Monday, April 14, at 8 p.m., in the Rooms of the Chemical Society, Burlington House, W. 1, when a report on the Examination of Oppau Ammonium Sulphate-Nitrate will be given.

The Physical Society of London is arranging to celebrate its jubilee from March 20 to 22 next. The preliminary programme of the proceedings will be as follows: On Thursday, March 20, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 2.30 p.m., there will be an Exhibition of Apparatus, followed by a reception at 3.0 p.m., and at 3.45 the Guthrie Lecture on "Photo-electric Effects in the case of High Frequency and Allied Phenomena" will be delivered by M. le Duc de Broglie. On Friday, March 21, from 4.0 to 5.30 p.m., and from 6.0 to 7.30 p.m., reminiscences by Original Fellows and other Follo[illegible]ng standing will be given, and on Saturday, Mar[illegible]e will be a continuation of the Exhibition, and [illegible]m. for 7.30 a banquet will be held for Fellows [illegible] guests only.

The Council of the Physical Society extends to the members of this Society a hearty invitation to be present at these meetings, and, according to present arrangements, no tickets will be required for this purpose.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

Patron: H.M. The King

PRELIMINARY NOTICE

The Annual Meetings of the Society will be held in Liverpool from Wednesday, July 9, 1924, until Saturday, the 12th inclusive.

His Majesty the King has been graciously pleased to grant his Patronage to the Meeting.

The Presidential Address will be delivered by Dr. E. F. Armstrong, F.R.S., and the Messel Lecture will be given by the Rt. Hon. Viscount Leverhulme.

A limited number of technical papers will be read, and there will be visits to at least two large works in the neighbourhood.

A very interesting programme is being arranged by the Local Committee under the Chairmanship of Mr. Edwin Thompson, who was largely responsible for the great success of the British Association meeting in September last.

Whilst the business and technical side will be adequately represented in the programme, arrangements will be made to make the meeting an attractive social event.

It is hoped that many of the Society's overseas members who are coming to this country to visit the British Empire Exhibition will arrange their visit so that it may be possible for them to be present at the Society's Annual gathering.

Further particulars will be intimated as arrangements are completed.

OFFICIAL NOTICES

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Vol. VIII is now in preparation and will be issued shortly. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members. Vol. I is out of print, but copies of Vols. II, III, IV, V, VI, and VII may be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d., and 7s. 6d., and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d., and 12s. 6d. respectively. If Vols. II, III, IV, V, VI, and VII are ordered at the same time as Vol. VIII, the set may be obtained by members for £2 2s. 6d., and by non-members for £3 15s. The appropriate remittance must accompany every order. The books are sent to purchasers post free.

DEATHS

Roberts, F. G. Adair (Original Member), of 68, North Gate, Regent's Park, London, N.W. 8. Chemical Manufacturer. On February 11, 1924.

Richards, Edgar (elected 1889), of 60, Ayrault Street, Newport, R.I., U.S.A. Analytical Chemist. On January 21, 1924.

Francis, W. H. (Original Member), of 11, Bramham Gardens, South Kensington, London, S.W. Wholesale Druggist. In May, 1923.

CHEMICAL ENGINEERING GROUP

On March 4 a joint meeting with the Hull Chemical and Engineering Society was held in Hull, and Mr. E. A. Alliott, B.Sc., M.I.Chem.E., read a paper entitled "Centrifugal Dryers, Their Construction and Use."

After a few remarks on the arts of drying and separating Mr. Alliott discussed constructional details of centrifugal dryers, beginning with the basket, that part of the apparatus which has most influence on the design. Various materials, steel, copper, aluminium, nickel, etc., are used to make the baskets, which are discharged by hand or through discharge doors; one type is ifted out. Speeds of running usually vary between 8000 to 12,000 ft. per minute, though small machines of 12 in., and less diameter may be run at 18,000 ft. per minute. After considering the relationships of running speed and size of basket, centrifugals were discussed under the headings of fixed spindle, suspended, and self-balancing machines. The behaviour of material in a centrifugal drier was dealt with and an account was given of various points connected with working practice, *e.g.*, the method of filling, the distribution of moisture in the load, and the effect of heat, size of grain, viscosity, and capillarity on drying. Figures were adduced to show the efficiency of "spinning" under commercial conditions and the question of labour and output was treated at length. The second part of the paper was devoted to centrifugal separators, beginning with a discussion of the chief features of emulsions and suspensions. A detailed account of separators, illustrated by practical data, was then given.

EDINBURGH AND EAST OF SCOTLAND SECTION

Two papers were read at the meeting held on February 12.

I "Factory Plant Records as a Control of Efficiency in Manufacture," by J. Adam Watson. The efficient working of any plant, and particularly of a chemical plant, can be most easily controlled by the use of a series of daily reports drawn from every section of that plant. These reports, which can be drafted so that their filling up by the departmental foreman every day will occupy little time, are then handed to a special Record Department. The duty of this department will be to tabulate the figures handed to it in such a way as to enable a diagram to be prepared at any desired time interval, which will show clearly the efficiencies of the plant in bulk and detail. The diagram which does this is the flow-sheet, which indicates the course of all material required to produce the article or articles being manufactured. It also shows the interdependence of the various departments. From the details so obtained it is readily possible by substituting cost for weight to obtain the price paid for the finished article. Also the labour necessary may be shown by noting against each stage the men-hours required for its production. This scheme provides a basis for issuing instructions to such subsidiary departments as the laboratory, buyers, etc., and at the same time it may be used to calculate a bonus for the workers. The adoption of such a system places in the hands of the management a mass of data which will be invaluable for improving the efficiency of the processes and determining the minimum price of the articles being manufactured.

II. "The Viscosity of Rubber Solutions," by C. L. Abernethy, M.A., B.Sc. The importance of viscosity determinations as a means of factory control has lead to the study of the factors controlling viscosity and of the methods of measuring it. The various methods were examined with reference to their suitability. for rubber solutions, and the falling sphere method was described in detail. By its aid the viscosities of solutions of well-milled smoked plantation sheet in benzene and toluene could be examined from 7½ per cent. up to as high as 30 per cent. or 40 per cent. concentration, the concentration being expressed as grams per 100 c.c. of solution. Curves were obtained for the viscosities of solutions up to 40 per cent., *i.e.*, 40 grams in 56 c.c. of benzene, at a range of temperatures from 10° C. to 60° C. The viscosity concentration curves were found not to obey Arrhenius' logarithmic law, $\eta = ke^{c}$, but to follow the law $\eta = Ke^{k\sqrt{c}}$, where K and k are constants depending on the nature of the rubber and on the temperature. The viscosity of the solid rubber could thus be obtained in absolute units.

MANCHESTER SECTION

A meeting was held on March 7 at the Textile Institute, Dr. Herbert Levinstein presiding. About 70 members and visitors were present, and Prof. F. Gowland Hopkins, D.Sc., F.R.S., read a paper entitled "Some Chemical Qualities of the Living Cell."

Prof. Gowland Hopkins said that as one who was more or less responsible for having introduced the conception of vitamins into science, he had frequently had to speak on that subject to medical and other audiences. The conception of a vitamin had certain encrustations about it which prevented everybody accepting what were really said to be very important scientific facts. He had not attempted to define a vitamin. In an adult community, under good economic conditions, the need for something other than a supply of energy did not seem to assert itself, because the vitamins were always present in all natural foods. Special circumstances were required to make their importance obvious, or they would have been discovered many years ago instead of in the past ten years or so. Being connected with the subject of diet, they naturally attracted the attention of quacks, and therefore a good deal of nonsense had been written about them, whilst, on the other hand, it was equally true what was written about vitamins gave a great opportunity for trade stunts. They had not yet been isolated, so that their chemical composition was unknown. What he wished to

urge was that the facts known about vitamins were important. An animal can be fed upon a diet consisting of the most excellent protein and really superior fat and best carbohydrate on the market, and give it the necessary salts in the right ratio. So long as those materials were pure and not mixed with traces of any other ingredient, the dietary would be eaten, enjoyed, fully digested, thoroughly broken down in the body, and its energy extracted, and yet any animal continuing to eat it would inevitably die. In order to convert that dietary into a perfect one for the maintenance of life, materials must be added which acted in almost infinitesimal concentration within the cellular structure of the living organism. The only present definition of a vitamin of a definite constitution was that it was a substance of extreme nutritive importance which acted in infinitesimal concentration. With Fat-Soluble Vitamin A 0·004 mg. added to a synthetic dietary made just the difference between certain death and excellent life in feeding a rat weighing 100 g. They must not despise the rat; it was, in all essentials, of the same physical constitution as human beings. With a 70 kg. man 2½ mgs. would be required to bridge the difference between health and death. Only under exceptional circumstances, such as a state of war, did the lack of vitamins affect adults, but the feeding of infants must be placed in a different category.

The living cell was pre-eminently a colloidal system, though this factor must not be dwelt upon too much if they were to understand its chemical activities. Its colloidal nature represented the essential apparatus. There were small molecules in solution which were able to undergo high-velocity reactions characteristic of life. The living cell contained 70 per cent. of water, and much of its material was in simple solution. The colloidal apparatus was relatively stable and was largely, if not entirely, protected from the oxidations which yielded a supply of energy to the cell, but, on the other hand, the form of the colloidal apparatus was all-important in determining what precise energy transformation should occur.

Prof. Gowland Hopkins also dealt with the question of food preservatives. It was extremely difficult for a physiologist, biologist or medical man to say whether long continued use of material which apparently produced little or no effect within a short period might not, in the course of years, have a deleterious effect upon health. One manufacturer would point out that the amount of preservative in his particular article was so small that it could not matter; it was far below the medicinal dose, and so on. This would be equally true of another manufacturer's article, and of a third, and perhaps of a fourth, and one individual would partake of all four articles in the same day. Upon going into figures, it was astonishing what a very large dose of boric acid the consumption of various articles of diet might involve. There were, of course, enormous trade interests to be considered in connexion with the supply of foodstuffs. They were all using infinitesimally small quantities of preservatives, and, in some cases, even dyes. The problem was whether there was likely to be any cumulative effect. Neither the manufacturer, the wholesaler, nor the retailer troubled themselves concerning this aspect of the problem. The living organism was at times astonishingly sensitive to small doses, and could also accumulate small doses until they became large. Of course, there was provision, for instance, that a dye should contain neither arsenic nor lead nor other poisonous substance. It was not the fault of anyone concerned in the preparation of foodstuffs that the present position of things was taken for granted, but the time had seemed to arrive when a new profession was required, or else the State should provide special Institutes where tests could be made which did not come under ordinary chemical technique. Drugs should be tested biologically, and foodstuffs for their food content. Living tissues were delicate, nicely balanced organisations and extremely sensitive to maltreatment.

NEWCASTLE SECTION

At the meeting held on February 25, a paper was read by Mr. C. W. H. Holmes, B.Met., on "Some Aspects of the Physical Properties of Moulding Sands for Foundries." Mr. Holmes first described the properties of a well-bonded moulding sand and pointed out the importance of the strength of the bond and the ratio of the various mechanical grades, a factor upon which depends the venting properties of the sand. He described the various methods of sorting out the different sizes of sand and described his modification of Crooke's elutriator for determining the proportions of the finer grades, which are impossible to determine on sieves. An account was also given of the latest method of determining the bonding factor by means of dye adsorption.

On March 3 a joint meeting was held in Middlesbrough with the local section of the Institute of Chemistry and the Cleveland Institute of Engineers. Mr. C. H. Ridsdale, F.I.C., read a paper entitled, "Engineers and the Interpretation of Chemical Specifications for Iron and Steel in Relation to Analytical Accuracy."

Exploration of the work of the British Chemical Standards' Movement had revealed data which should have practical bearing on the interpretation of chemical specifications. The engineer provided exact measurements for section or length as well as the weight, but for composition all that was given was a figure on paper that had no exact meaning; its value was determined arbitrarily after the steel had been made by analytical operations subject to ever varying personal and other factors so that another test of the same sample might yield a different result. So, although the maker's own chemist might find the material right he could never be sure it would not be rejected. Small differences near the border-line—quite within the range of working of good chemists—might be enough to cause rejection. For the same reason exaggerated importance was apt to be attributed both to the influence of small quantities of impurities and to trifling differences in results; no allowance however was officially recog-

nised for differences which analysts usually gave in practice, which were distinct from differences arising during manufacture and recognised as inevitable.

If instead of the maker having to work to and be judged by an unfixed and unascertainable (by him) value, the composition figure was specified in terms of a definite standardised sample the values of which had already been determined, how much more satisfactory for all concerned. This would be tested side by side with the sample of steel made, and, by its agreement with or divergence from its acknowledged standard figure, would at once reveal whether or not the working and results of both were correct. In the preparation of standard analysed samples important factors which tended to differences between chemists in ordinary work were removed. Yet whenever a large number of chemists (10 to 20) tested the same sample the final carefully considered results had shown an appreciable variation. The question thus was whether there was justification for regarding any result by one or even two or three chemists as right, except to within a similar range of variation, and whether it was reasonable that material should be rejected solely for wrong composition, when the variation from the figure specified did not exceed that by which the reference or any chemist might be in error?

These facts and considerations were submitted the General Meeting of the British Chemical ndards' Movement held on February 9, 1923, their views were embodied in a resolution stating he rejection of steel or cast iron is not warranted on chemical analysis alone.

The Committee of the Chemical Standards movement then sent out a circular letter to about 550 co-operators, users of standards, and others, asking for their opinion on a table showing that the tolerances which would seem reasonable for analytical determination of composition were really very small when compared with those actually granted for other properties of material, such for instance, as variation in weight and length.

TOLERANCES OFFICIALLY GRANTED FOR WEIGHT AND LENGTH AND THOSE PROPOSED FOR COMPOSITION.

For	Per Cent. Plus or minus for normal conditions.	
Weight	1·0	granted, see B.E.S.A. specifications.
Length	0·05	

Composition		Actually Found under exceptionally favourable conditions.	suggested
	%	%	%
Carbon, up to ..	0·35	0·025†	0·015
	0·36—0·75	0·033	0·020
	0·76—1·20	0·05	0·025
Silicon up to ..	0·10	0·025	0·015
	0·10—0·20	0·032	0·020
Sulphur up to ..	0·08	0·0077 (0·008)	0·005
Phosphorus up to	0·05	0·0062	0·005
over	0·10	0·012	0·007
Manganese, plain Carbon steels up to	0·45	0·021	0·015
	0·46—1·0	0·048	0·025

† The percentages of variation found and suggested for composition are (as with weight and length) percentages of the whole 100 units, not of the total of the particular element determined only.

The tolerances tentatively suggested were slightly above one half the range of variation found with work under exceptionally favourable conditions. Out of all the replies, not one objected outright to the principle though several said the tolerances were not sufficiently large, or raised partial objections. Two or three others did not feel disposed to offer any opinion, but the vast majority approved both of the principle and the amounts. The replies were clearly representative of the interests concerned.

The fact of these differences between chemists, even when doing the most careful work, could not be gainsaid, and showed that they caused considerable trouble, and did not improve the status of the chemist in the eyes of engineers and commercial men. Did they really matter in practice? A difference of 0·005 per cent. might look a lot as compared with a total of 0·03 per cent., but it was really only one twenty-thousandth of the unit. A solution would be for chemists not to report to the third decimal place, at any rate by less than 0·005 per cent. at a time, otherwise it would be imperative to allow such differences at the tolerances. If it was contended that figures should be reported to such a degree of fineness, the only way was for chemists still further to improve their working. In that case it was imperative that everything should be done to facilitate the desired exactitude. To this end, engineers should supply, or at least refer to definite standards obtainable by all, just as they stated the composition itself, and both makers and chemists ought to regard these standards not merely as a convenience to be supplied or used at option, but as a necessity for which they had a right to demand. However, these differences and difficulties would ultimately be removed, the more the subject was ventilated and discussed between engineers, managers and chemists, the sooner would this come about. We had as an example, the splendid work of the British Standards Association. True, they only made recommendations, not laws, but these were becoming more and more effective every day, and we could only expect the British Chemical Standards Recommendations to take effect in the same way for chemical specifications.

The Lord President of the Council has appointed Mr. F. S. Sinnatt, M.B.E., M.Sc., to be Assistant Director of Fuel Research as from April 1. Mr. Sinnatt is Lecturer in Fuels in the University of Manchester, Faculty of Technology. He is also Director of Research to the Lancashire and Cheshire Coal Research Association, and has been in charge of the physical and chemical survey of coal seams which the Association is carrying out for the Fuel Research Board in the Lancashire and Cheshire fields.

CHEMICAL SOCIETY

The third Hugo Müller lecture was delivered on Thursday, February 28, by Prof. J. Joly, Professor of Geology in Trinity College, Dublin. The lecturer was introduced by the President, Prof. W. P. Wynne, who briefly referred to the advantages of the application of physical science to geological investigations.

Radioactive studies, said Prof. Joly, were of special interest in that they appeared to throw light on the past history of the elements. Lord Rayleigh's observations, eighteen years ago, that acid rocks contain a larger quantity of radioactive material than the basic rocks, and that the igneous contain more than the sedimentary, had since been confirmed. The precise value of the ratio of the content of uranium to that of thorium, for which an approximate average figure was 0·9 : 2, was not important, or indeed constant, since the rates of decomposition of uranium and thorium are unequal, the former being thrice as great as the latter. The results which he had to communicate were favourable to the view which had been adopted by many geologists, namely, that there is a primary basaltic magma on which the superstructure of the continents floats. It was of importance to note that the first silicates which were formed in the igneous rocks, the zircons, are exceptionally rich in uranium. The lecturer suggested that an explanation might be sought in the isomorphism of zirconium oxide with the oxides of uranium and thorium.

Prof. Joly then proceeded to give an account of the "haloes" to which this concentration of radioactive elements in rocks gives rise. These circles, which have a radius of about 0·003 mm., and could readily be observed with a good microscope, were in fact cross sections of spheres around a zircon centre, and were due to the penetration of the material by α-rays; their existence was at one time erroneously ascribed to the presence of organic matter, since the bands fade when the material is heated. (Their appearance as concentric light and dark bands was illustrated by a number of photomicrographic lantern slides.)

Three kinds of haloes were due, respectively, to uranium and its family, to the thorium family, and to emanation; in the case of the last-named a photograph showed the effect of the passage of emanation through interstices in the material, and the formation of haloes at points where, presumably, the radioactive material became arrested by adsorption. It was possible to distinguish clearly between the haloes due to uranium and those due to thorium by measurement of the radii, and comparison (assuming, however, that the rays are parallel) with the known degree of penetration in air of the α-rays from various sources; in the case of mica, the ranges for air must be divided by 2000. The lecturer hazarded the opinion that the effect was an alteration in the molecular condition of the iron by α-rays, since iron-free materials never exhibit haloes. If it were assumed that a rock contained twenty-five times as much uranium as was present in Lord Rayleigh's richest sample of zircon, calculation demonstrated that the clearly observed haloes originated from an amount of uranium no greater than 3×10^{-18} gram.

In some cases the light and dark areas of the haloes were reversed; the phenomenon was explained by the lecturer as being parallel to the known reversal of photographic images by over-exposure to light. Thus partial or complete bleaching of portions of the mica may result from over-exposure to the ionising α-rays. It is supposed that in the case of new micas (one hundred million years) there has not been time for reversal, whilst in the case of the old micas (two hundred million years) such reversal has taken place. The nature of the halo depends also on the radioactive strength of the nucleus.

Examination of an old mica—Ytterby mica—had led to the detection of the presence of three different varieties of haloes which could not be identified with those due to any known element. Two of these, called respectively X_1 and X_2, of which the smaller corresponded with an α-ray penetration in air of 1 cm., might be produced by any existing element, such as a rare earth, or by an element which has now disappeared by disintegration; the third could only be ascribed to a hitherto unrecognised element, to which the name "hibernium" had provisionally been given.

Prof. Joly concluded by remarking how few of the existing elements are radioactive, but that this comparatively scarce phenomenon was involved in the genesis of the elements. The studies which he had described carried one back to events of two hundred million, possibly even a thousand million, years ago.

Prof. H. B. Dixon, proposing a vote of thanks to the lecturer, said that the discourse to which they had just listened was one of the most delightful, as regards both material and delivery, he had heard. Borrowing a phrase from Mr. Pickwick, he asked them to "surround with a halo of united cheering" the name of Prof. Joly—physicist, chemist, geologist—the Hugo Müller lecturer for 1924.

Seconding, Dr. A. S. Russell expressed thanks for a most interesting and stimulating lecture, dealing with a fascinating area of junction of the sciences. He asked whether one of the haloes might be due to an element of the actinium series, and whether the α-ray of 1 cm. penetration in air might be due to the head member of the polonium group.

The motion for the vote of thanks, when put by the President, was carried with acclamation.

Prof. Joly, after brief acknowledgment, said that he had considered the actinium question, but was unable to endorse the suggestion. He regarded that element as a side branch of the uranium line, and not strong enough to produce a halo by itself.

At an ordinary meeting on Thursday, March 6, 1924, the President, Prof. W. P. Wynne, announced that nominations to vacancies among the Officers and Council had been received as follows: To be one of the Secretaries, Prof. C. S. Gibson; as Vice-Presidents who have filled the office of President, Prof. Sir J. J. Dobbie and Prof. W. H. Perkin; as Vice-Presidents who have not filled the office of President, Mr. A. J. Greenaway and Prof. J. C. Philip; as members of the Council (Town), Dr. O. L. Brady,

Dr. A. E. Dunstan, Prof. T. S. Moore (County), Mr. B. Lambert, Prof. F. L. Pyman, Prof. D. R. Boyd. As the number of nominations did not exceed the number of vacancies, no ballot would be necessary this year.

The President reminded Fellows that the Annual General Meeting would be held at 4 p.m. on Thursday, March 27, and would be followed by an Informal Dinner, tickets for which could be obtained from the Assistant Secretary for the sum of 7s. each. He hoped that, whether they chose to wear evening or morning dress, a large number of Fellows and their guests would be present.

Prof. J. R. Partington gave an account of experiments on :—

The reaction between lime and nitrogen peroxide. J. R. Partington and F. A. Williams.

THE reaction between pure nitrogen dioxide and lime has been investigated, and it has been shown that the products of reaction are calcium nitrite, calcium nitrate, nitric oxide and nitrogen. The proportion of calcium nitrate in the product is more than equivalent to the calcium nitrite. The loss of nitrogen as elementary gas varies, the maximum being about 5%. The existence of the hydrate of calcium nitrite, $Ca(NO_2)_2$, $4H_2O$ has been confirmed. The thermal decomposition of calcium nitrite has been found to commence at 230°, the products below 480° being calcium nitrate, calcium oxide, nitric oxide and nitrogen. Above 480°, nitrogen dioxide is also obtained. It has been proved that calcium nitrite is readily oxidised to calcium nitrate by nitrogen dioxide, which is reduced to nitric oxide and nitrogen. The nitrogen set free during the reaction of nitrogen dioxide and lime is due to this reduction. Calcium nitrite when heated in oxygen below its decomposition point (230°) was found to remain unoxidised, but on admitting nitrogen dioxide oxidation occurred, the dioxide being alternately reduced to nitric oxide and reproduced from this by oxidation with free oxygen.

Prof. F. G. Donnan congratulated the authors on the thorough way in which the reaction had been examined, the President referring also to the interest of a detailed study of the behaviour of nitrogen dioxide in the manufacture of sulphuric acid.

Prof. Partington also described the following confirmatory experiments :—

Tellurium monoxide. By J. J. Doolan and J. R. Partington.

THE experiments of Divers and Shimosé on the production of tellurium monoxide by heating tellurium sulphoxide, $STeO_3$, in a vacuum at 180°, were repeated and confirmed. The product had the properties described by Divers and Shimosé, and the results obtained by Weber are therefore incorrect.

Dr. S. W. Smith agreed that difficulties arose in the assay of tellurium ; fusion with litharge at a low temperature was necessary. He had reason to think that the reaction, $2PbO+Te=Pb_2O+TeO$ took place when the buttons of lead containing tellurium were fused with litharge, for the black substance in the mass was soluble in concentrated sulphuric acid.

Prof. Partington said that although one would not expect the tellurium monoxide to exist at the temperature employed—it decomposes at an undetermined temperature above 180°—it might exist in the presence of litharge. Elementary tellurium requires the use of fuming sulphuric acid for its dissolution.

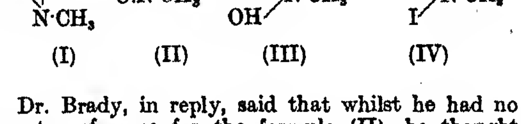
Dr. O. L. Brady discussed :—

The isomerism of the oximes. Part XVII. The action of 1-chloro-2:4-dinitrobenzene on some isomeric aldoximes. By O. L. Brady and R. Truszkowski.

1-CHLORO-2 : 4-DINITROBENZENE reacts with the sodium salts of substituted benz*anti*aldoximes to give dinitrophenylethers which have the *syn*-configuration since they are decomposed, on being warmed for a short time with alcoholic sodium hydroxide, with the formation of sodium dinitrophenoxide and the corresponding nitrile. *o*-Hydroxybenz*anti*aldoxime does not react in this way and in a few other cases the yield of ether is small. With the sodium salts of *syn*-aldoximes a complicated reaction occurs but from the products only sodium dinitrophenoxide and the corresponding aldehyde could be isolated. The binary fusion curves of the *anti*-oximes and chloro dininitrobenzene indicate that in certain cases well defined additive compounds are formed consisting of equimolecular amounts of the two components. That stable additive compounds with chloro dinitrobenzene were characteristic of those oximes which could readily be converted into *syn*-isomerides seems to support the view that the formation of additive compounds is at the base of isomeric change in the oximes.

Prof. T. M. Lowry pointed out that the greater tendency of a reactive compound to form additive products was observed also in other cases.

Prof. J. F. Thorpe considered that the Beckmann change itself was a proof of the Hantzsch-Werner hypothesis. He preferred, however, the ring-formula (I) to the alternative (II) employed by Dr. Brady :—



(I) (II) (III) (IV)

Dr. Brady, in reply, said that whilst he had no great preference for the formula (II), he thought that there was some justification for it, in that the great solubility of the compound in water (III), its ready formation of additive compounds (IV), and the shift in the position of the absorption band might thus be accounted for.

The President doubted whether a sodoxyl group and an iodine atom could be attached to the same nitrogen atom.

Prof. C. S. Gibson described :—

The dimorphism of diphenylarsenious chloride (diphenylchloroarsine). By C. S. Gibson and the late D. C. Vining.

The dimorphism of diphenylarsenious chloride, which has not been previously recorded in the literature, has been definitely established. The unstable form, which melts at 18·2–18·4°, forms colourless, silky needles. The stable form, m.p. 38·7–38·9°, forms rhomb-shaped biaxial doubly refracting crystals. Both forms have a normal molecular weight in benzene solution. The boiling point of pure diphenylarsenious chloride is 178·6°/10 mm.

Prof. Gibson said that his results absolutely confirmed those of Dr. N. V. Sidgwick, of whose work he had only recently been made aware, and to whom he was indebted for some of the material.

Dr. Sidgwick, expressing gratification that the results were identical with those obtained under his direction, said that he believed that in America the material could not be obtained in the solid condition until it could be seeded with that from unexploded German shells. Unlike Prof. Gibson, however, he had experienced no difficulty in obtaining the unstable form. The material was such as to cause the investigator extreme physical discomfort.

Dr. M. A. Whiteley recalled that the first specimen which she received, when sent to another laboratory, arrived in the solid form ; a few hours after the siphon, with solid at the nozzle, had been returned, the whole of the material had solidified.

Prof. Gibson said that no difficulty was experienced in working with the liquid substance, but the solid was unpleasant to manipulate.

ROYAL MICROSCOPICAL SOCIETY

A meeting was held on February 20, Mr. A. Chaston Chapman, F.I.C., president, in the chair, and Mr. W. E. Hall read a paper entitled "A Simple Apparatus for the Extraction of Micro-Organisms from Samples of Water."

The microscopical examination of samples of water is greatly facilitated by means of the following simple apparatus. The sample is collected in a small straining jar through which any quantity of water can be passed and the organisms retained in a quantity of water convenient for carriage.

From this concentrated sample the organisms can be extracted by passing it through a filter paper about 1¾ in. diameter placed over a small funnel attached to a vessel from which the air is extracted by means of an exhauster consisting of a modified form of filter pump.

The organisms are finally washed [illegible] the filter paper by means of a wash bottle with about 2 c.c. of water in which the organisms can readily be examined in a stage trough or placed in small quantities on a compressor slide.

INSTITUTE OF CHEMISTRY

At the 46th Annual Meeting of the Institute c Chemistry on March 3, the Meldola Medal, th gift of the Maccabæans, was presented to Mr. C N. Hinshelwood, B.A. (Oxon). The Medal is awarde for the work of most promise published by a Britis chemist under thirty years of age, brought to th notice of the adjudicators during the year.

Mr. A. Chaston Chapman, F.R.S., the retirin President, in his address referred to the growin activity of the Institute during his three years c office. The roll of membership had increased b 1129, and about 1000 new chemists had bee absorbed into useful professional life. He empha sised that the Institute endeavoured to counterac the modern tendency to turn out narrow and impe fectly educated specialists. He deplored the tendenc on the part of Government Departments to unde value professional scientific and technical servic especially in view of the fact that the public chemica service is becoming every year a more importar part of the machinery of government.

Dealing with the proposals for closer co-operatio amongst chemical societies, which he though should have the warm support of all, he expresse the hope that in any scheme of co-operation th Institute would not sink any of its individualit The general public was coming more and more t recognise in chemistry one of the most powerfu factors in the creation of material wealth, at a tin when it is more important to create wealth than t quarrel about the distribution of what little the wa had left us. He quoted Mr. Baldwin, the late Prim Minister, who, in a recent speech at Glasgow, ha said that under the stimulus of the war we had mac great headway in pure chemistry, and we had schoo of chemistry in this country which compared wit any in the world. We should take care that ou industries absorbed the output of those school and should not be content to run only rule-of-thum industries and leave those more highly organise industries, which depend upon science and bra power, to the foreigner. He felt that those word had a very special significance with reference to th reported negotiations between the British Dyestuf Corporation and the Interessen Gemeinschaft.

The new President, Prof. G. G. Henderson, F.R.S Regius Professor of Chemistry in the University c Glasgow, was formally installed.

The officers, Council and Censors for 1924-2 were elected as follows :—

Vice-Presidents :—Prof. E. C. C. Baly, C.B.E F.R.S., A. Chaston Chapman, F.R.S., A. Mor Dr. T. Slater Price, O.B.E., Prof. A. Smithell C.M.G., F.R.S., and Dr. E. W. Voelcker.

Hon. Treasurer :—Mr. Patrick H. Kirkaldy.

General Members of Council :—L. Archbutt, D E. F. Armstrong, F.R.S., E. R. Bolton, Prof. A. Boon, Dr. F. D. Chattaway, F.R.S., R. Leslie Collet Dr. H. G. Colman, John Evans, Dr. R. H. Greave Prof. A. J. Hale, Mr. G. Nevill Huntly, Prof. W. Lewis, W. McD. Mackey, Dr. H. McCombie, D [illegible]; Dr. R. S. Morrell, G. H. Perry, O.B.E., Pr[illegible]y, Philip, O.B.E., F.R.S., Dr. R. H. Pickard [illegible]

B. D. Porritt, Prof. F. L. Pyman, W. D. Rogers, H. Silvester, Dr. Arthur Slator, Prof. J. F. Thorpe, O.B.E., F.R.S., Dr. J. F. Tocher, Dr. D. F. Twiss, Prof. F. J. Wilson.

District Members of Council:—Dr. L. Dobbin (Edinburgh), H. J. Evans (Liverpool), Dr. W. R. Fearon (Irish Free State), Dr. W. H. Gibson, O.B.E. (Northern Ireland), C. A. F. Hastilow (Birmingham and Midlands), E. M. Hawkins (London and South-Eastern Counties), R. D. Littlefield (Bristol and South-Western Counties), S. E. Melling (Manchester and District), Dr. L. G. Paul (North-East Coast) C. A. Seyler (Wales), and J. H. Young (Glasgow and West of Scotland).

Censors:—Mr. A. Chaston Chapman, F.R.S., Sir Herbert Jackson, K.B.E., F.R.S., Prof. G. T. Morgan, O.B.E., F.R.S., and Sir Robert Robertson, K.B.E., F.R.S.

On March 5, a paper was read before the Leeds Area Section of Chemistry, by Dr. N. M. Comber, entitled "The Fertilisers and Feeding Stuffs Act and the Professional Aspects of Agricultural Analysis." The author said the Fertilisers and Feeding Stuffs Act was only partially successful. The checking by analysis of the guarantees under which fertilisers and feeding stuffs are sold was almost inoperative in some parts of the country. This was largely due to the fact that local authorities and official samplers are under no obligation to take samples except at the request of the purchaser and on payment by him of a prescribed fee. A compulsory and uniform scheme of sampling, as required by the Food and Drugs Act, seemed very desirable. The Act would operate more fairly to the seller if criminal proceedings only arose on the basis of the analysis of samples taken before delivery. At present the analysis of samples taken up to ten days after delivery may be used for criminal proceedings. The contents of the warranty which the Act demands could be usefully revised. All forms of quicklime and carbonate of lime should be included among the fertilisers, and the carbohydrate and maximum fibre content of feeding-stuffs should be included in the guarantee.

In addition to the provisions of the Fertilisers and Feeding Stuffs Act, facilities are offered by some educational authorities for analyses to be carried out for the information of a farmer at nominal fees. This raised an important point of professional etiquette. In general, it seemed obvious that Educational Authorities should only undertake analyses the results of which would have a definite educational value and which would help to elucidate hitherto unsolved problems. The situation, however, was more complicated than it appears to be: no hard and fast rule could be put forward, and the difficulty would probably be most effectually overcome when all chemists concerned in agricultural analysis were members of the Institute of Chemistry.

Soil analysis was at present in the research stage and must be considered separately. It was difficult [illegible] any justification for the analysis of soil samples [illegible] undertaken by consulting analysts, as the [illegible]tical data considered alone were of minor [illegible] for any immediate practical purpose.

SOCIETY OF GLASS TECHNOLOGY

At the meeting in Sheffield on February 20, two sessions were held. In the morning there was an exhibition and demonstration of modern pyrometers at the Department of Glass Technology of the University. The following firms exhibited:—1. The Bowen Instrument Co., Ltd.; 2. The Cambridge and Paul Instrument Co., Ltd.; 3. The Foster Instrument Co.; 4. The Optical Pyrometer Syndicate; 5. Messrs. Booth and Miller also demonstrated their New Temperature Controller.

At the afternoon session the subject under discussion was "The Use of Pyrometers in Glass Works." Five papers were presented.

I. "The Use of Pyrometers in Glass Works," by E. A. Coad-Pryor, B.A. The value of pyrometric equipment in a glass factory depended essentially on three factors:—(1) The reliability of the pyrometer itself, particularly the clock-work; (2) The skill which is expended on its maintenance; and (3) The attitude with which the management, foremen and furnace operators regard the pyrometer. Of these three the last was the most important. The pyrometer in no way displaced the trained eye; its real function was to supply further information in order that a highly skilled operator might be able to get more out of his plant than had hitherto been possible.

The range of temperatures to be measured could conveniently be subdivided into three groups. (1) The range 0° to 700° C., covering lehrs, stack temperature, producer gas, etc. (2) From 700° to 1200° C., regenerator temperature, pot work, and (3) Above 1200° C., the temperature of the melting furnaces.

In the first group the thermo-couple was the most convenient instrument to use. Some sort of a portable thermo-couple should be part of every works equipment. A convenient couple for low temperature work was iron-constantan: the wire to be about 22 gauge.

In the high-temperature ranges an optical or total radiation pyrometer was, as a rule, the most convenient. The tank furnace might be subdivided into three zones; the melting zone, the plaining zone, and the refining end. Two permanent pyrometers should be used on each furnace, one on the refining end, the other sighting through a hole in the end wall at the melting end of the furnace. The use of couples embedded in the wall of the tank or in the crown caused probably more trouble than they were worth.

The optical or radiation pyrometer if used with discretion, was the most reliable and the most easily applied. The author's experience was that the optical instruments gave less variable readings than did the radiation instruments. The all important factor was the training of the staff and operators to use the instruments as an aid to the maximum efficiency in furnace manipulation.

II. "Continuous High-Temperature Measurements in Glass Works," by W. M. Clark, Ph.B. (U.S.A.). There was probably no absolutely accurate method existing for constantly determining glass-house temperatures. We could only approach this desirable

aim by refinements of installation and careful maintenance, and this meant both equipment and maintenance expense. Therefore, in considering a pyrometer installation the glass manufacturer must decide what his demands for accuracy will be worth against the initial and operating costs of various systems. It is always advisable to install both the indicating and recording type of instrument side by side. Experience at a number of modern plants showed that pyrometric measurements were reflected in the costs sheets. The morale of the furnace men was improved by eliminating errors due to guessing at temperatures, and cost per unit of output decreased. The depreciation on pyrometric equipment was not excessive, about ten per cent. per annum being a fair amount, judging from successful installations and improvements could be incorporated into the system, replacing features which became obsolete and thus keeping the installation up to date. A well planned system would reduce overall costs in a year more than sufficient to pay for the investment and often would leave several times this amount if used intelligently. The most forceful argument for the adoption of pyrometer control in a glass works was on the score of economic savings, but the information thereby made available to the management and staff was also important in showing each man a tangible effect of his operation on the thermal conditions.

III. "Recent Advances in the Design of Temperature Measuring Instruments, etc.," by R. W. Whipple. One difficulty of disappearing filament pyrometers was to get two lamps which would be interchangeable. Methods for overcoming this difficulty were indicated. He had been much impressed with what he had seen recently in the United States in the matter of automatic temperature control. Considerable work was being done in glass works, such as those of Messrs. Keuffel and Esser, where lehr temperatures were controlled from 200° C. to 600° C. For every kind of glassware a special cooling curve was followed. In the United Kingdom automatic temperature control was being developed. The main principle in such control was a galvanometer needle which was deflected by some method. Lantern slides were then exhibited showing various forms of controller, including (1) Brown, (2) Bristol, (3) C. Engelhard, (4) Leeds and Northrup, (5) Cambridge, (6) Barr, (7) Althorpe.

IV. "Practical Applications of Pyrometers to Glass Works," by C. E. Foster, F.Inst.P. Both optical and total radiation instruments were calibrated for what were known as "black body" condition and when used on hot bodies which were not technically "black bodies" the reading would be in error by an amount which varied with the actual condition. An ordinary large glass melting tank was by no means a "black body." The author suggested that luminous gas flames might have the power of selective emission, that is, they radiated a light which was not in proportion to their temperature, but might be of an intensity which would correspond to the brightness of a solid hot b[illegible] at a much higher temperature. Considering a [illegible] of molten glass viewed obliquely in a furna[illegible] did not realise "black body" conditions, it obviously had a considerable reflecting power, but its reflecting power as experienced in measuring with a total radiation pyrometer was relatively much less than the unoxidised surface of molten metal. This was reasonable because there was some considerable transparency in the glass so that it would actually emit a greater proportion of the heat from inside. Thus it was actually found that molten glass approached more nearly to a true "black body" than unoxidised molten metal.

V. "Reflections on Pyrometer Design," by W. Bowen. Economy in fuel consumption, long life of furnaces or other heating devices employed, elimination of waste of raw materials and of irreparable losses of finished products all depend upon the raising of the heat-treated materials to no less, and no more, than the requisite temperatures. A few of the standards which a good pyrometer should fulfill were discussed with reference to the new "Pyro" radiation pyrometer, an instrument compact in shape, extremely portable and simple in operation.

ACADÉMIE DES SCIENCES

On February 18, Dr. Roux described the work of M.M. Sergent and Rougebief on the dissemination of grape yeasts by insects. The authors concluded from their experiments that certain insects, particularly *Drosophyla*, play an important part in spreading the yeast. Dr. Roux also communicated a note by Monsieur Mazé, indicating that in the manufacture of Cantal cheese the peptisation of the casein is accompanied by putrefaction if the medium is insufficiently acid. To avoid this phenomenon it is suggested that a suitable lactic ferment should be introduced during manufacture to maintain a sufficient degree of acidity.

Monsieur Perrin described a method worked out by Monsieur Tien for measuring very small quantities of heat, and drew attention to Monsieur Kuhn's work on the action of ultra-violet rays on ammonia.

On February 25, Prof. C. H. Moureu read an account showing how Maurice Barrès, the distinguished French writer who died recently, had foreseen the part that science would play in deciding the future of the country, and recognising the valuable work he did in helping the movement in favour of scientific research. Professor Moureu then communicated a paper by MM. Dufraisse and Gillet on "Curious Stereo-chemical Observations in the Series of Benzalacetophenone." Monsieur Le Chatelier communicated a note by Monsieur Chesneau, showing the similarity in the chemical composition of the glass in ancient windows of ages varying by 100 years. Monsieur Schloesing described work by Monsieur Lebedantshev on the chemical and biological modifications undergone by dried soil, showing that drying reduced to one-third, and even one-tenth, the microbial fauna and flora of the soil. Monsieur D'Arsonval presented a note by Monsieur Villard on a direct-reading actinometer for the measurement of solar ultra-violet.

CORRESPONDENCE

A CORRECTION

SIR,—As I did not see the proof before publication of a short article on the derivation of the word "Mercaptan," which you were good enough to publish in your issue of February 22, perhaps you would allow me here to make a correction in regard to a small point, which, nevertheless, gave me some trouble. The earliest information of Zeise's discovery appeared, as I state (page 197) in Schweigger-Seidel's *Journal für Chemie und Physik*, 1833, Vol. 8, *but of the 3rd series*, which is Vol. 68 of the whole series, and is at the same time also the 8th volume of Schweigger-Seidel's "Neues Jahrbuch der Chemie und Physik."—I am, Sir, etc.,

University of Glasgow

COLLOID CHEMISTRY

SIR,—Referring to the letter of Mr. A. V. Slater on page 38 of your current volume, I would call the attention of your readers to the fact that about the end of this year I expect to complete a comprehensive international book on "Colloid Chemistry, Theoretical and Applied," to which over 150 of the best men of all nations have already promised contributions. Of these 19 are citizens of the British Empire, and I expect that other Englishmen will also write.

Papers have already been received from R. Zsigmondy, E. F. Armstrong, A. Mary, E. E. Ayres, C. Barus, C. Benedicks, H. J. Creighton, W. P. Davey, A. E. Dunstan, F. Emslander, H. Freundlich, C. I. Fulmer, G. Georgeivics, R. A. Gortner, L. Gurwitsch, W. B. Hardy, A. L. Herrera, H. N. Holmes, S. Leduc, Dorothy Jordan Lloyd, J. Uri Lloyd, R. Lorenz, A. Lumiere, Luppo-Cramer, G. D. McLaughlin, E. J. Mardles, P. H. Prausnitz, H. R. Procter, M. Sameo, H. N. Spencer, W. H. Martin, N. Waterman, T. Hagiwara, S. Utzino, M. Toch, F. Zerban, and H. Schado. Many others are either in the mail (T. Braisford Robertson and P. P. von Weimarn) or else will soon be ready (W. D. Bancroft, H. Bassett, G. Bredig, W. Clayton, H. A. Gardner, E. Hatschek, W. H. Herschel, F. E. Lloyd, R. E. Liesegang, D. T. MacDougal, L. Michaelis, Sven Oden, A. B. Searle, S. E. Sheppard, W. E. S. Turner, and many others).

If any of your readers can send me reprints of papers germane to the subject, or suggestions as to points they would like to have included or discussed, I shall appreciate it and make the best use I can of the information.

Meanwhile, let me say that I hope to see the British Reports continued as heretofore. The University of Wisconsin has just issued as a Monograph the papers read there before the First National Symposium on Colloid Chemistry, and the Second Symposium will be held next June at Northwestern University, Evanston, Ill. The more helpful information published on the subject, the better for industry and for the chemical profession.—I am, Sir, etc.,

JEROME ALEXANDER
New York, Feb. 6, 1924

HYDROGEN PEROXIDE AS A BLEACHING AGENT FOR GELATIN

SIR,—I read with interest your report of a meeting of the Nottingham Section of the Society of Chemical Industry, which appears on page 226 of your *Journal* of February 29, 1924.

I was astonished at Mr. Trotman's reply to Mr. Pentecost on the use of hydrogen peroxide for bleaching and preserving gelatin. His statement that hydrogen peroxide is not being used for this purpose is entirely wrong. He would, no doubt, be surprised to learn that my firm, Messrs. B. Laporte, Ltd., has supplied hydrogen peroxide in large quantities for the bleaching of gelatin for the past twenty years. To-day it is being used more than ever for bleaching gelatin made from either bones or fleshings.

I should like to call Mr. Trotman's attention to the following, which I have taken from page 246 of "Animal Proteins," by Mr. H. G. Bennett, M.Sc., published by Messrs. Bailliere, Tindall and Cox, in the Industrial Chemistry Series. Mr. H. G. Bennett, whom I have the pleasure of knowing personally, has had a large experience in the bleaching of gelatin with hydrogen peroxide, so that his remarks are based on practical experience.

"On account of its freedom from bases, and because its residue is simply water, peroxide of hydrogen has been found of great service in practice, and in most factories it has shown itself superior not only to the other peroxides, but also to all other oxidizing agents. Its application is simple, a concentrated solution being added to the gelatine sol before or after evaporation. It is the most "foolproof" of all the oxidizing agents used in bleaching, and it yields the purest product. Its bleaching action is perfectly satisfactory, but only in a non-acid sol. Hydrogen peroxide is moderately stable in acid solution, and its bleaching action is best in slightly alkaline solution. An acid sol bleaches too slowly, or not at all; an alkaline sol induces evolution of oxygen and consequent waste. The great disadvantage of peroxide of hydrogen is its great expense, which is enhanced by an increasing demand for it in other industries. A minor disadvantage is its instability, which leads to loss in transit and storage. It is sold usually in strengths indicated by the volume of oxygen obtained from unit volume of the solution, when treated with permanganate in a nitrometer (*e.g.*, "15 vols. peroxide,").

It is a fortunate feature of both the oxidising and reducing agents usually employed in bleaching, that they have considerable antiseptic power. This assists materially in preserving the gelatin from putrefaction during the critical period between extraction and concentration"

Mr. Bennett wrote his book in 1921; since then the price of hydrogen peroxide has been reduced considerably, so that its use for bleaching gelatin has become more than ever a sound commercial proposition. In addition, its extended uses in other industries has helped to lower the price, owing to increased production.—I am, Sir, etc.,

PROF. H. BAKER'S EXPERIMENTS

Sir,—It occurred to me some time ago that a substance which might be used to test the various hypotheses put forward to explain the experiments of H. B. Baker is liquid nitrogen tetroxide. In this the two forms NO_2 and N_2O_4 are known to be present, and the change from one to the other is easily followed by the change in colour. If one takes the liquid at room temperature it is deep orange red; this changes to pale yellow in a freezing mixture. If now the liquid at room temperature is dried, it may change to pale yellow, if polymerisation has occurred, or, if the colour persists it may also persist in a freezing mixture if drying fixes the equilibrium $N_2O_4 \rightleftarrows 2NO_2$ at ordinary temperature. It should therefore be possible, if this is a suitable liquid, to decide between two theories, and I am carrying out experiments on these lines.—I am, Sir, &c.,

J. R. Partington

Chemical Research Laboratory,
East London College

MAGNESIUM OXYCHLORIDE CEMENT

Sir,—With reference to the article by Dr. J. H. Paterson in *Chemistry and Industry* of February 29 1924, it is to be regretted that the article contains many inaccurate statements.

In view of the importance attached to opinions expressed in the *Journal of the Society of Chemical Industry* these mis-statements should not go uncorrected.

Dr. Paterson states :—

I. That in pre-war days the bulk of the magnesia used in this country was imported from Hamburg, and was there made by the calcination of magnesite rock imported from Euboea.

II. During the war a large amount of magnesite was shipped from India and calcinod in this country, but it did not yield a very satisfactory product, and the high cost of carriage has made its use prohibitive since that period.

III. The calcined material is ground in tube or ball mills.

IV. If the temperature of burning is carried above 1000° C., the resulting product will not react with magnesium chloride.

V. The kilns used are frequently of the beehive type.

The facts are :—

I. In pre-war days the caustic burning of magnesite was chiefly carried out in Euboea and India, and the lump calcined material was shipped to Holland, where it was ground and distributed. A small quantity of the lump calcined material went to Hamburg, where it was ground, and and then distributed chiefly to Germany and the United States of America. Hamburg was not a calcining centre.

II. With regard to India—during the war and since—both caustic calcined magnesite and crude magnesite have been and are being shipped to this country.

Indian crude magnesite is recognised as being of exceptionally high grade.

It was not calcined here, however, during the war to produce caustic or plastic material, but to obtain dead-burnt magnesite to be used for making refractory magnesite bricks. It was necessary, during the war, to produce magnesite bricks in this country on a large scale as the Austrian supply had been cut off. Owing to the high degree of purity of both Indian and Grecian magnesite, and the unsuitability of the kilns in this country for calcining at sufficiently high temperatures, there was difficulty i thoroughly dead-burning these magnesites, bu this difficulty was overcome to a large exter by adding oxide of iron or an iron salt to tl magnesite. Dr. Paterson seems to have confused the Indian and Grecian calcined magnesites, which contain only about 0·2 per cent. oxide of iron, with the Austrian magnesite containing about 7 per cent. oxide of iron. The latter is quite unsuitable for cement purposes, but is highly valued as a refractory material.

Indian magnesite has been regularly shipped to this country since the war, but owing to ship-building and other strikes consumption has been curtailed.

During the latter part of 1922 Indian causti calcined magnesite was introduced to America and now commands there, because of its quality, a premium in price over the domestic product. The following statement based on authoritative figures from Washington shows that during the first half of 1923 the total imports of Indian caustic magnesite were almost equal to double the total of all other magnesites imported into the United States during the same period.

Magnesite imported January to June, 1923, inclusive :—

	India.	Greece.	Germany.	Scotland.	Netherlands.	Italy
	Per cent.					
Jan. ..	—	—	—	—	99·9	0·1
Feb.	87·2	—	—	2·6	10·2	—
March	49·4	—	1·2	11·2	38·2	—
April	65·2	—	—	—	34·8	—
May	72·4	6·1	2·7	—	18·8	—
June	60·5	—	1·6	7·7	30·2	—
Total for six months	64·73	1·77	1·24	3·33	28·89	0·0007

The demand for Indian magnesite has since increased.

III. Calcined caustic magnesite is largely ground under millstones.

IV. Indian and Grecian magnesites, even when calcined at a temperature over 1000° C., will re-act with magnesium chloride.

To dead-burn these magnesites, *i.e.*, to carry to the stage when the resulting product will be inert and shrunk, requires a temperature of over 1500° C.

V. The kilns used are *not* frequently of the beehive type. In Euboea, India and the States the kilns used for producing caustic calcined magnesite are generally gas-fired shaft kilns.

CO-OPERATION AMONGST CHEMICAL ASSOCIATIONS

SIR,—On two occasions the Editor has devoted a portion of his particular space in the *Journal* to the subject of the multiplicity of chemical meetings and societies. With all the statements in these articles we are in complete accord, and we feel with him that the time for effective co-ordination of effort is now, not in a few years to come. At the present time even the most cheerful optimist must feel that the condition of the chemical trade and profession could be bettered. Now, to the improvement of the conditions there must be devoted every scrap of information that has any bearing on technical chemistry. When trade is good the necessity is not so great for keeping in close touch with the scientific world, but with high manufacturing costs on the one side and a sluggish market on the other the industrial chemist should study any scientific research which, however remotely, may bear on his special work. This necessitates the reading of current literature; yet under such conditions as the present the expense of subscriptions is most felt and the tendency is to resign rather than to take up membership of societies, although the latter may be the wiser course. This being the case, it would seem to be an opportune time for the various societies to embark on a scheme of co-operation that will make more easy the application of chemical science to the needs of the country. Chemistry is a fundamental branch of science or knowledge, and any attempt to differentiate between the academic and industrial side is not only arbitrary, but tends to lessen the appreciation of those members of the community who are not initiated into its mysteries. And on these very members chemical industry depends for its success. One ideal to be kept in view is a central body which will be able to speak authoritatively for chemistry. We are aware that this is foreshadowed by the scheme for the establishment of a "Chemistry House," and we have confidence in this coming to full fruition. Yet, if chemistry is to do its duty in shortening the present period of depression we cannot wait on this accomplishment. If the two main societies, the Chemical Society and the Society of Chemical Industry, would come together and discuss the means whereby their publications can be combined and issued at an economic rate to the chemical public we feel sure that they would have the support of the bulk of their members. In this discussion let them keep in their minds as an ultimate end the publication of an international journal of chemistry which shall contain abstracts of all chemical work. Thus and thus only will be avoided the duplication of effort to be seen in the publications of the chemical societies throughout the world. It is not now that the individuality of societies should be considered. If one may have a longer and more brilliant history than the others, yet their ultimate objects are the same—the dissemination of useful knowledge, and in the fulness of time the honour of the older society will be enhanced when it is found that by sinking its individuality it has increased the value of the science which gave it birth.

As yet the profession of chemistry has no rules: each member plays a lone hand with no guidance but his own personality. In this we differ from other professions. Conventions, the slow growth of generations, do not yet govern our doings, yet on convention depends the strength of any country or community. Let us, then, proceed to form our rules and laws. To do this, we must come together, we must co-operate, we must work with an eye on the common good of our professional brethren, and, to do this effectively, scientific information must be readily available and this can only be accomplished by the societies who are the trustees for the scientific world.—I am, Sir, etc.,

J. ADAM WATSON

THE STATUS OF CHEMISTS AND CHEMISTRY

SIR,—Mr. Claremont's letter in your issue of March 7 is a most useful contribution to the discussion which has centred recently about the question of the status of chemists and chemistry. As he points out, the fact that the personal services of chemists are not likely to be required by the average member of the public makes it improbable that anything will be done by the Government to lay down a definite professional status for the chemist. We must all share his hope that in future professional chemists will come to regard the qualifications of the Institute as a necessary part of their equipment, for whilst chemistry can never be a closed profession like medicine or law, a really strong and representative Institute could do much to consolidate professional chemists and to secure for chemistry a worthier place in the public status.

When all is said and done, however, we are bound to recognise that a correct public estimation of the importance of chemistry can only arise from an enlightened public knowledge of the functions and services of chemistry, which, in turn, can only develop from a wider education and interest in chemistry and kindred sciences. The lack of acquaintance among educated people with even the most elementary facts concerning chemical processes and raw materials is still remarkable, though an improvement is occurring in this respect. The story is still told of a Minister, a member of the War Cabinet, who, finding the conversation at a certain dinner turning to the sinister menace of the submarine campaign, then at its height, and its effects especially on the Chile communications, turned to his neighbour with the enquiry: "Tell me, what is this nitrate they are all making such a fuss about?"

The analogy which Mr. Claremont brings out between chemistry and engineering does not extend to the public recognition of these professions. In the first place, engineering in its numerous branches is an industry employing a far larger number of work-people, and to that extent bulks more largely in the public eye. Further, the man-in-the-street can comprehend a bridge, a power-station, a battleship, or an aeroplane, as something built up by human agency, but gallic acid might be a synonym for cheap French wine ... [illegible] ...losive

for all he can tell without specific information, and one liquid or powder looks much like another.

We have to look for improvement in our status in the first place to the concerted efforts of professional chemists themselves, acting each in his own sphere, and together through the Institute, and in the second place to a gradual enlightenment of the public through education, exhibitions, lectures, etc., as to the social importance of chemistry.—I am, Sir, etc.,

STANLEY I. LEVY

THE EDITOR IS ADMONISHED

SIR,—I am a very humble individual, a regular Uriah 'Eep, but thank goodness I can always kick an editor. That is the unalienable right of every Scotsman.

I am out to criticise. Why, why, did you compare the profession of chemistry with law? Do you not see that it is the same as a comparison between a thoroughbred racehorse and the vermiform parasite which infests its bowels. Chemistry, the greatest productive science which has in its applications made civilization, and on which with its fellow sciences all the wealth, prosperity and progress of the world have been built, you compare with the pettifogging law founded on the sin, misery, chicanery and errors of humanity. I don't like it, Mr. Editor, and I just feel like "Coffee and pistols for two."

Again, you go into high politics. Now the late trouble on the Continent is outwith our purview. Instead of talking of apologies, why don't you get up some practicable scheme to benefit everyone. For example, preach the doctrine that an international language of science is essential. Take Volapuk or Esperanto, add thereto an efficient, flexible vocabulary suited specially to the needs of scientific description. Get this introduced into the schools instead of French or German, and gradually get all scientific literature printed in this language.

Recently I had to hunt up information on some enzymes, and I had to get translated papers in Japanese, Russian, Italian, French and German, incurring considerable expense and loss of time.

Now there is a job to your hand. It would in time do more for international amity than possibly any other scheme. I believe the time is ripe for a start.

Growth would be gradual, but in time it would arrive at fruition. Consider the advantages. Any book could be sent anywhere and read with exactly the right shades of meaning. Students could go from one country to another independent of language. Doctors, chemists, physicists and biologists all the world over would be bound by the tie of language.

Of course, all we can do is to start it, but posterity might count it as an offset against the awful debt we leave them.

Be higher in your ideals, Mr. Editor. We are the salt of the earth.—I am, Sir, etc.,

CAREY LAW

Paisley

PERSONAL AND OTHER NOTES

His Majesty the King has been graciously pleased to grant his Patronage to the Annual Meeting of the Society of Chemical Industry, which will be held in Liverpool in July.

Mr. W. A. Turner, a founder and the managing director of W. T. Owbridge, Ltd., manufacturing chemists, died recently at Hull.

Monsieur R. Masse, president of the Cie. Francaise d'Éclairage et de Chauffage par le Gaz, and of the Cie. Nationale des Matières Colorantes, has been promoted Commander of the Legion of Honour.

The Gold Medal of the Institution of Mining and Metallurgy has been awarded conjointly to H. W. Gepp, M.Inst.M.M., and Gilbert Rigg, M.Inst.M.M., in recognition of their joint and individual services in the advancement of metallurgical science and practice, with special reference to their achievements in the treatment of complex sulphide ores, and in the development of the electrolytic process for the production of zinc in Australia.

Prof. Sir D. Orme Masson, K.B.E., who has retired from the chair of chemistry in Melbourne University, will shortly pay a visit to England. Prof. J. A. Schofield, of the Chemical Department, Sydney University, is also coming to Europe on a visit this year.

Prof. N. Parravano has been appointed corresponding editor to represent Italy on the Committee for the International Critical Tables published by the International Research Council.

Mr. N. J. T. M. Needham, Gonville and Caius College, Cambridge, has been elected to the Benn W. Levy research studentship in biochemistry.

The eleventh election to Beit Fellowship for Scientific Research will be held in July. Information can be obtained from the Rector, Imperial College of Science and Technology, South Kensington, S.W. 7. Applications must be received by April 19.

Mr. A. F. Wenger, who died recently at Newcastle-under-Lyme, was the founder and principal of Wengers, Ltd., Stoke-on-Trent, manufacturers of ceramic colours.

Oil Discovery in Holland

The Government Mineral Research Department has been drilling in Eastern Holland for a year, where salt and coal have been brought to the surface, and now reports, states the *Times*, a discovery of oil near Winterswyk. In one place a deep bore was made, but as nothing of particular interest was found, it was decided to dismantle the workings, but during the dismantling a weak stream of light petroleum, greenish in colour, suddenly came to the surface. Twelve gallons were collected, and the hole was closed, but on February 26 was reopened, when several barrels were filled. It is not yet known whether the quantities are sufficient for the establishment of a petroleum industry in Holland.

REVIEWS

NICKEL ORES. *Monograph issued by the Imperial Institute. Pp.* 80. *London: John Murray. Price* 5*s*.

"Nickel Ores" commences with a short sketch, historical, mineralogical and metallurgical, and the main part of the work is devoted to the sources of supply of nickel ores in the British Empire and in foreign countries. Statistics for production are given for the eight-year period 1913-1920. The world's production of ore in terms of metal content averaged about 30,000 tons annually for 1913 and 1914, increased to as high as 47,000 tons in 1918. The estimate attributed to the Metallgesellschaft that the production fell quite so low as 5000 tons in 1921 is incorrect; the official Canadian figures alone amounted to 9600 tons. It may be added that the Caledonian production in 1921 was practically nil, but that re-production commenced again in 1922. There are potential supplies of nickel in many countries, but the world's production is almost exclusively derived from Canadian and New Caledonian sources. The monograph is provided with the usual excellent references to the literature of the subject. W. G. WAGNER

SANDS AND CRUSHED ROCKS. *By* ALFRED B. SEARLE. *Vol. I, Their Nature, Properties and Treatment. Pp. xiv*+475. *Vol. II, Their Uses in Industry. Pp. viii*+281. *London: Henry Frowde and Hodder and Stoughton*, 1923. *Price* 52*s*. 6*d*.

In compiling these volumes Mr. Searle has drawn copiously on the publications of H.M. Geological Survey and the Memoirs on Resources of Glass-making and Refractory Sands by Prof. P. G. H. Boswell, but errors have crept in which are not present in the memoirs. The introductory chapters on the geology of sand deposits, etc., are very loosely written, and would not receive the approbation of a geologist.

A very wide interpretation of the subject of the volumes has been made, and it is a little difficult at times to see any connexion between the matter introduced and "Sands and Crushed Rocks." The portions of the book dealing with the mechanical devices used in the quarrying and treatment of sands and rocks contain a good deal of data and illustrations extracted from trade catalogues which may be of use to quarrymasters and managers. W. J. REES

THE CHEMISTRY AND PHYSICS OF CLAYS AND OTHER CERAMIC MATERIALS. *By* ALFRED B. SEARLE. *Pp. xiii*+695. *London: Ernest Benn Limited*, 1924. *Price* 55*s*. *net*.

There is need for a book which critically sums up the modern views on the properties of refractory and ceramic raw materials and products, but that need is certainly not met by the present volume. The contradictions, misconceptions and mistakes in the book are so numerous as to necessitate an unhesitating condemnation of it. As a contribution to the literature of refractory materials the book is of little or no value. W. J. REES

COMPANY NEWS

MAGADI SODA CO., LTD.

On February 13, an extraordinary general meeting was held to consider a resolution to place the company in voluntary liquidation and to appoint a liquidator and an advisory committee to co-operate in the liquidation of the company and its proposed reconstruction. During the discussion, the chairman, Mr. Samuel, M.P., said the fact that he had rendered himself liable for over £250,000 to try to save the company, was sufficient proof that he had confidence in its future. Altogether roughly a half million of fresh capital would be required, but it was estimated that £250,000 would be sufficient to turn the company into a profit-making concern. As the result of a poll the resolution was carried.

At the statutory meeting of creditors, the receiver and liquidator stated that total liabilities were £2,316,244, and there was a debit on the profit and loss account to November 30, 1923, of £693,317. Attempts had heen made to formulate a scheme of reconstruction, and it was possible that shortly a proposal might he made to provide the necessary working capital otherwise than by the shareholders. A creditor opposed these schemes, and asserted that negotiations had been taking place with Brunner Mond and Co. As no resolutions were passed the voluntary liquidation will be continued.

THE BRITISH ALIZARINE CO., LTD.

For two years after 1920 when the capital was considerably increased and a dividend of 10 per cent. was paid, the profits of the British Alizarine Company considerably contracted and no distribution was declared. Last year there was a very pronounced recovery, net profit, after setting aside £20,000 for depreciation, going up from £5,000 to £24,100. This enables the directors to resume the payment of dividends and the shareholders will get 5 per cent. less tax, though in former years the tax has heen paid for them. There then remains to go forward £42,900, as against £36,600 brought in. The directors have therefore treated the avaliable surplus in a very conservative manner. Stocks and open accounts figure for £245,400, as against £188,500. The indehtedness to the bank has increased from £191,700 to £208,600.

INTERNATIONAL PAINT AND COMPOSITIONS CO., LTD.,

At the ordinary general meeting the Chairman said that the profit for 1923, after writing off bad debts, was £55,689, as compared with £37,462 in 1922. It was proposed to place £15,000 to general reserve, to apply £6000 to the payment of a final dividend of 3 per cent. less tax, on the preference shares, making the full 6 per cent. for the year, and to apply £19,000 to the payment of a dividend of 5 per cent. less tax on the ordinary shares for the whole year. Investments stood at £201,736, compared with £187,289. The increase was mainly accounted for by investments in associated companies lately established in Spain and Austria. The

acquisition of the undertaking of the Standard Anti-fouling Composition and Paint Co., Ltd., had brought the company a substantial amount of additional business in the course of the past year. Although there was said to be a slight improvement in the shipping depression, no less than 1,000,000 tons of British shipping was still laid up, and there was no great hope of any marked change in the immediate future. Nevertheless, the directors were assured by experts that trade was improving, and if this opinion proved to be correct, better trade ought before long to bring about more employment of shipping, and consequently a greater demand for the company's goods. They were relieved at last of the incubus of depreciated stocks, and were beginning to reap the fruits of their acquisition of the Standard Co.

UNITED TURKEY RED CO.

Profits during 1923 were £210,263, and deducting the deficit (due to depreciation of stocks) of £54,037 brought forward, £156,226 is available. After paying all arrears and preference dividends for 1923, there is a balance of £81,488, of which £40,000 is placed to reserve. It is proposed to pay 2½ per cent. (tax free) on the ordinary shares for the year, leaving £24,421 to be carried forward.

BRADFORD DYERS' ASSOCIATION, LTD.

In the absence of Sir Milton Sharp, Mr. G. Douglas presided over the annual general meeting on February 28. After reviewing the difficult trading conditions of the past year, Mr. Douglas said that the figures of exports did not bear out the statement that the high price of dyeing had crippled the trade and led to an increased export of grey goods. Dyeing prices were approximately 10 per cent. lower, though this economy was counter-balanced by higher prices for raw cotton and wool. From 70 to 80 per cent. of the Association's requirements in dyes was drawn from British makers, who were making undoubted progress in reliability and quality, though, without question, they could not live under existing conditions without the protection of the Dyestuffs (Import Regulation) Act. The Association, together with all the other colour users, had expressed, both to the directors of the British Dyestuffs' Corporation and to the Board of Trade, disapproval of the terms of the proposed agreement between the Corporation and the German Interessen-gemeinschaft. Profits for 1923 were £546,403, to which was added £448,369, leaving £994,772, of which £125,000 was carried to reserve (now £1,125,000) £271,295 was allocated for the payment of 4s. per ordinary share (making 5s. per share for the year) and £473,477 carried forward.

ELECTRO BLEACH AND BY-PRODUCTS, LTD.

The profit for the year ended December 31, 1923, after deducting all charges, is £52,047, to which is added £1245 brought forward. Final dividends are recommended of 6¼ per cent. on the preference shares (making 10 per cent. for the year) and of 13 per cent. on the ordinary shares (making 20 per cent. for the year), whic[illegible] bsorb £26,000. It is recommended that a [illegible] be carried to reserve (which becomes £55,000 and £3201 carried forward.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Expiring Patents

Mr. Alexander said that Mr. G. Oliver's proposal as to the advisability of inquiring into the practicability and desirability that all expiring patents now in use should become the property of the nation, had already been considered, but was not thought to be in the public interest.—(Feb. 21.)

Census of Production in Trade and Commerce

Mr. Webb, in answer to Mr. Nichol, stated [illegible] steps would be taken to reinstitute the nat[illegible] census of production, suspended during the [illegible] period, and that it had been decided that a Ce[illegible] should be taken next year in respect of the pre[illegible] year.—(Feb. 26.)

Patent Fees

Answering Mr. Smedley Crooke, Mr. Webb said that the average fees received on applications for patents amounted to rather more than £3 per application. The patents maintained in force for the full term of 16 years were about 4 per cent. of the total number granted. Replying to Lieut.-Comm[illegible] Burney and Mr. Crooke, he said he believed the [illegible] of the Patent Office did not do appreciably more than maintain the Patent Office. It was not practicable to reduce the British scale of fees at the present time nor was it possible to establish a fair basis of comparison between British and American fees owing to difference in practice with regard to the permissible scope of a single patent and other consideratio[illegible] —(Feb. 26.)

League of Nations (Scientific Property)

Answering Sir C. Marks, Mr. Ponsonby stated t[illegible] the report on scientific property prepared by [illegible] League of Nation's Committee was under conside[illegible] tion by the Departments concerned, and that [illegible] would not be in a position to state the views of the Government until their reports had been receiv[illegible] —(Feb. 26.)

Reparation Coal and Coke Deliveries

Mr. W. Graham, replying to Mr. Ayles, said [illegible] the average monthly deliveries of coal (includ[illegible] coke expressed in terms of coal) made by Germany [illegible] reparation account were 1,500,000 tons for the y[illegible] 1921 and 1,505,000 t. for 1922. According [illegible] information supplied by the British delegate of t[illegible] Reparation Commission, it was believed that t[illegible] average monthly quantities obtained by the Alli[illegible] concerned, was as follows:—January to Septemb[illegible] 1923 (passive resistance period) (including a monthl[illegible] average of 129,600 t. to Italy on reparation accou[illegible] 547,700 t., and October, 1923, to January, [illegible] (after passive resistance ceased and including up [illegible] December 17, a certain quantity delivered to It[illegible] on reparation account), 996,400 t.—(Feb. 27.)

White Lead (Geneva Convention)

In reply to Lord H. Cavendish-Bentinck, Mr. Shaw said that the Home Secretary hoped to introduce, as soon as possible, a Bill designed to give [illegible] to the provisions of the Convention which [illegible]

[illegible] concerning the prohibition of the use of white lead for interior painting. Should this Bill pass into law without amendments contrary to the provisions of the draft Convention, it was proposed to ratify the Convention.—(Feb. 27.)

British Beet-Sugar

Mr. Graham, answering Mr. Gilbert, said that the amount of Excise Duty that would have been payable on home produced sugar had the duty not been repealed as from July 20, 1922, would have been approximately £140,000 and £250,000 for the output in the 1922-3 and 1923-4 campaigns.—(Feb. 28.)

Chemists under British Dyestuffs Corporation

Mr. Webb informed Mr. Graham White that the number of chemists in the employ of the Corporation engaged on research was 51.

Safeguarding of Industries Act (Amendment)

A motion by Mr. Remer that leave be given to introduce a Bill to amend the Safeguarding of Industries Act in respect of goods made under conditions not allowed by trades unions or by law in Great Britain, was defeated by 228 votes to 157.—(Mar. 4.)

Imports from Germany

Replying to Sir F. Wise, Mr. Lunn furnished figures showing the declared value of articles classed as wholly or mainly manufactured imported into the United Kingdom, and registered as consigned from Germany during 1921, 1922 and 1923:—

	1921	1922	1923
Earthenware, glass, abrasives ..	1272	1292	1541
Iron and steel and manufactures thereof	2600	1951	1819
Non-ferrous metals and manufactures thereof	1489	898	838
Cutlery, hardware, implements, and instruments	1200	1744	1792
Chemicals, drugs, dyes and colours	2122	2399	2558
Oils, fats and resins manufactured	25	125	237
Leather and manufactures thereof	623	1060	1522
Paper and cardboard	872	1154	2513
Rubber manufactures	139	426	482

The figures relating to 1923 include from April 1 of that year the trade of Great Britain and Northern Ireland only with Germany, the direct imports of the Irish Free State from Germany having been excluded from the accounts from that date.—(Mar. 5.)

Nauru Phosphates

Mr. Smith informed Mr. Blundell that trials to test the value of the Nauru phosphate had been conducted in several centres during the past three years. In the first season conditions were unfavourable. The results obtained in the second season were not conclusive, and in the last the results were not yet fully available. In any case the value of raw phosphate could not be satisfactorily determined until after several seasons, but as soon as any conclusive results were obtained these would be published.—(Mar. 6.)

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

In spite of labour troubles the demand for heavy chemicals is well sustained, but there are no fundamental changes in prices to report. The effect of the revision of the German reparation levy is somewhat obscure, and it remains to be seen whether the rebate of the duty will be counterbalanced by the increased cost of manufacture, caused partly by the stabilisation of the currency. The only alteration of note is a reduction in the price of sodium bisulphite by about £1 per ton.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5½d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In
Sod. Bisulphite Powder 60/62%	Prices reduced to £18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis ..	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb. according to

Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow 1s. 11d. per lb.
Cadmium Sulphide .. 4s. per lb.
Carbon Bisulphide .. £24—£26 10s. per ton according to quantity.
Carbon Black .. .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride .. £56 per ton, drums free.
Chromium Oxide .. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark } 5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black .. .. 40s. per cwt., barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Thiocarbanilide .. .. 2s. 9d. per lb.
Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—
Brown .. .. .. £14 10s. per ton d/d. Demand active.
Grey .. .. .. £21 per ton.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 10s. per ton, according to grade and locality. Market steady.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. " " 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 5s. per gall. 60% O.P. Dull market.
Solvent .. .. 5s. per gall. 40% O.P. Dull market.
Wood Tar .. .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead .. £47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 7½d.—8d. per lb. Better demand, and firmer market. London prices reported up to 9d.
Crude 60's .. .. 2s.—2s. 3d. per gall. Firmer, with more inquiry. Tendency to higher values.
Acid Cresylic, 97/99 .. 1s. 11d.—2[illegible] per gall. Demand still good. Market firm.
Pale 95% .. .. 1s. 10d.—2s. per gall. Steady demand.
Dark .. .. 1s. 8d.—1s. 11d. per gall. Steady business.
Anth[illegible] Past[illegible] .. 4d. per unit per cwt. Nominal price. No business.
[illegible]
Strained .. .. 10d.—11d. per gall. Very quiet.
Unstrained .. .. 8½d.—9d. per gall.

Benzole—
Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.
Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 8d.—1s. 11d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 11d.—11½d. per gall. Few inquiries
Middle Oil .. .. } 8½d.—9½d. per gall. according to grade and district. Market easier.
Heavy .. .. ..
Standard Specification
Naphtha—
Crude .. .. 8d.—9d. per gall. } Better demand. Prices show upward tendency.
Solvent 90/160 .. 1s. 2d.—1s. 4d.
Solvent 90/190 .. 1s. 1d.—1s. 3d.
Naphthalene Crude—
Drained Creosote Salts £7—£8. Demand still good.
Whizzed or hot pressed £10—£14 per ton. Not much inquiry.
Naphthalene—
Crystals .. .. £16 10s. per ton.
Flaked .. .. .. £17 per ton.
Pitch, medium soft .. 65s.—70s. per ton. Better demand for prompt and forward delivery. Prices hardening.
Pyridine—90/140 .. 16s.—17s. per gall. More demand at higher prices than of late. In the South as much as 17s. 6d. has been quoted.
Heavy .. 11s.—12s. Steady with fair business.

INTERMEDIATES AND DYES

Business in dyestuffs is maintained, but without much improvement. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. 4s. 6d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 4d.—1s. 5d. per lb. Steady demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 29/31° C. .. 5d. per lb. Demand moderate.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. [illegible]

Diphenylamine ..	.. 3s. 3d. per lb. d/d.
Monochlorbenzol	.. £63 per ton.
α-Naphthol ..	.. 2s. 6d. per lb. d/d.
β-Naphthol ..	.. 1s. 1d. per lb. d/d.
α-Naphthylamine	.. 1s. 5d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline ..	.. 5s. 3d. per lb. d/d.
p-Nitraniline ..	.. 2s. 5d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 11½d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol..	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s. 6d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 6d. per lb. 100% basis d/d.
R. Salt	.. 3s. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 7d. per lb. 100% basis d/d.
o-Toluidine ..	.. 7d.—8d. per lb.
p-Toluidine ..	.. 3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine	.. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The principal items are in good demand for home trade and export orders generally show some indication of an improvement, which is expected to continue. In some products, however, weakness is evident and prices fluctuate within comparatively wide limits.

Acid, Acetic 80% B.P. ..	£52 per ton.
Acid, Acetyl Salicylic	.. 3s. 6d.—3s. 8d. per lb. Weaker tendency.
Acid, Benzoic ..	.. Commercial acid 2s. 9d. per lb. B.P. quality remains scarce at 4s. per lb.
Acid, Boric B.P.	.. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric..	.. 18s.—20s. per lb. Business normal.
Acid, Citric ..	.. 1s. 5½d. per lb., less 5% for ton lots. Market firm.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst...	6s. per lb., for 28 lb. lots.
Acid, Salicylic ..	.. English make, 2s.—2s. 6d. per lb., which is below the price of imported material. Various prices quoted for different brands.
Acid, Tannic ..	.. 3s. 0d. per lb. for B.P. quality
Acid, Tartaric ..	.. 1s. 1d.—1s. 1½d. per lb. less 5%. Firmer with more demand Continental acid offered at 1s. per lb. less 5% c.i.f. U.K. port.
Amidol	.. 9s. per lb. d/d
Acetanilide ..	.. 3s. per lb. Weaker. Offers are being made down to 2s. 10d. to stimulate the demand.
Amidopyrin ..	.. 13s. 3d. per lb. Demand negligible.
Ammon. Benzoate	.. 3s. 9d. per lb. English make.
Ammon. Carbonate B.P.	£37 per ton. Price advanced.
Atropine Sulphate	.. 12s. 6d. per oz. for English make. Market neglected.
Barbitone.. ..	.. 15s. per lb. Weak market.
Benzonaphthol ..	.. 6s. per lb. Firmer.
Bismuth Salts ..	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
„ Citrate ..	.. 11s. 4d.—13s. 4d. „
„ Salicylate	.. 10s. 2d.—12s. 2d. „
„ Subnitrate	.. 10s. 9d.—12s. 9d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.

Bromides—	Per lb.
Potassium ..	.. 9½d.—10d. English make. No alteration of any moment.
Sodium ..	.. 9½d.—10d.
Ammonium ..	.. 10½d.—11d. Foreign prices are somewhat unsteady. A lot of damp sodium bromide is being offered.
Calcium Lactate	.. 2s. 6d. per lb. for best English make. Prices steady.
Chloral Hydrate ..	.. 3s. 9d. per lb.
Chloroform ..	.. 2s. per lb. for cwt. lots.
Creosote Carbonate	.. 6s 0d. per lb. Little demand.
Guaiacol Carbonate	.. 12s. 6d. per lb. for small stocks available.
Hexamine ..	.. 3s. 9d. per lb. for foreign makes. Weaker. Large supplies available.
Homatropine Hydrobromide	.. 30s. per oz.
Hydroquinone ..	.. 3s. 9d. per lb. Foreign make.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate— Light Commercial	.. £36 per ton net.
Magnesium Oxide— Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 6d. per lb., according to quantity. Steady market.
Menthol— A.B.R. recryst. B.P.	.. 56s. per lb. Slightly dearer, but market rather erratic.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials ..	.. Prices reduced. Market quiet.
Red oxide ..	.. 4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	.. 3s.—3s. 1d. „
White precip. ..	.. 4s. 1d.—4s. 2d. „
Calomel ..	.. 3s. 5d.—3s. 6d. „
Methyl Acetanilide	.. 20s. per lb.
Methyl Salicylate	.. 2s. 8d.—2s. 10d. per lb. for carboys. Slightly easier.
Methyl Sulphonal	.. 24s. per lb. Scarce.
Methylene di-tannin	.. 7s. 6d. per lb. In good demand.
Paraformaldehyde	.. 3s. 6d. per lb., without much inquiry.
Paraldehyde ..	.. 1s. 5½d.—1s. 8d. per lb. in free bottles and cases.
Phenacetin ..	.. 6s. 6d.—7s. per lb. Dull.
Phenazone ..	.. 7s. 6d. per lb. for cwt. lots. Spot prices much lower than forward offers.
Phenolphthalein ..	.. 7s. 3d.—7s. 6d. per lb. Firm.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 88s.—90s. per cwt., less 2½%. Firm market. Inquiry good.
Potass. Citrate ..	.. 1s. 8d.—2s. per lb.
Potass. Ferricyanide	.. 3s. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	.. 7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	.. 8½d.—9d. per lb. for B.P. crystal English make.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 6s. 3d. per lb.
Salol	.. 4s. per lb. Price fluctuates.
Silver proteinate	.. 10s. per lb.
Sod. Benzoate, B.P.	.. 3s. 3d. per lb. In more plentiful supply.

Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.	
Sod. Hyposulphite—Photographic ..	.. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.	
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.	
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.	
Sod. Potass. Tartrate (Rochelle Salt)	.. 76s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.	
Sod. Salicylate ..	.. A weak market with various prices quoted. Powder 2s. 7d.—2s. 10d. per lb. Crystal at 2s. 7d.—2s. 11d. per lb. Market weaker.	
Sod. Sulphide—Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.	
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.	
Sulphonal.. ..	.. 18s. 6d. per lb.	
Tartar Emetic ..	.. 1s. 4d. per lb.	
Thymol	.. 13s. 3d.—14s. per lb. for good white crystal from ajowan seed. Somewhat cheaper than of late.	

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d.	per lb.	
Aubepine	.. 13s. 6d.	,,	
Amyl Acetate ..	.. 3s.	,,	
Amyl Butyrate ..	.. 7s. 3d.	,,	
Amyl Salicylate ..	.. 3s. 6d.	,,	
Anethol (M.P. 21/22° C.)	3s. 9d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d.	,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d.	,,	
Benzaldehyde free from Chlorine ..	.. 3s. 6d.	,,	
Benzyl Benzoate..	.. 3s. 9d.	,,	
Cinnamic Aldehyde Natural ..	.. 17s. 6d.	,,	
Coumarin ..	.. 20s.	,,	Cheaper.
Citronellol ..	.. 16s.	,,	
Citral	.. 10s.	,,	
Ethyl Cinnamate	.. 15s.	,,	
Ethyl Phthalate..	.. 3s. 9d.	,,	
Eugenol	.. 10s. 9d.	,,	
Geraniol (Palmarosa)	.. 35s.	,,	
Geraniol	.. 10s.—17s. 6d.	per lb.	
Heliotropine ..	.. 8s. 3d.	per lb.	Cheaper.
Iso Eugenol ..	.. 15s. 9d.	,,	
Linalol ex Bois de Rose..	20s.	,,	
Linalyl Acetate ..	.. 20s.	,,	
Methyl Anthranilate	.. 9s. [illegible]	,,	
Methyl Benzoate	.. 6s.	,,	
Musk Ambrette ..	.. 52s. 6d.	,,	
Musk Xylol ..	.. 19s.	,,	
Nerolin	.. 4s.	,,	
Phenyl Ethyl Acetate	.. 12s. 6d.	,,	Advanced.
Phenyl Ethyl Alcohol	.. 16s.	,,	
Rhodinol ..	.. 57s. 6d.	,,	Cheaper
Safrol ..	.. 1s. 10d.	,,	
Terpineol ..	.. 2s. 9d.	,,	
[illegible] ..	.. 26s.	per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 14s. 6d. per lb.	
Anise Oil	.. Advanced to 2s. per lb. Firmer market forward.	
Bergamot oil ..	.. 15s. 6d. per lb.	
Bourbon Geranium Oil ..	29s. 6d. ,,	
Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil, Java	.. 9s. 3d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	Advanced. Market firm.
Cassia Oil, 80/85%	.. 9s. 3d. per lb.	Cheaper.
Citronella Oil—Java 85/90% ..	.. 5s. 3d. ,,	Much firmer.
Ceylon	.. 3s. 9d. ,,	Slightly dearer.
Clove Oil	.. 8s. 6d. ,,	
Eucalyptus Oil 70/75%..	2s. 3d. per lb.	
Lavender Oil—French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil ..	.. 3s. 2d. ,,	
Lemongrass Oil	.. 2½d. per oz.	
Orange Oil, Sweet	.. 12s. 6d. per lb.	
Otto of Rose Oil—Bulgarian ..	.. 30s. per oz.	Market recovered.
Anatolian ..	.. 24s. 6d. per oz.	
Palma Rosa Oil ..	.. 18s. 6d. per lb.	
Peppermint Oil—English ..	.. 70s. per lb.	
Wayne County	.. 18s. 6d. per lb.	Advanced.
Japanese ..	.. None offering on spot. 17s. per lb. offered.	
Petitgrain Oil ..	.. 9s. 6d. per lb.	
Sandal Wood Oil—Mysore	.. 25s. per lb.	
Australian ..	.. 21s. per lb.	

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

Canada: Copper sheets (251); *Dominican Republic:* Hollow-ware (1006/8/F.G/E.C/2); *Egypt:* Cement, paint, oils (271); *Iceland:* Sugar (262); *Italy:* Silk (263); *Netherlands:* Leather (264); *Rumania:* Glassware (268); *South Africa:* Leather (253); Steel (13,267/E.D.); *Sweden:* Chemicals (269); *United States:* Rubber, Vegetable oils, copra, tin (272); Iron and steel, brass, tinplate (273).

French Company News

The Société de l'Artois Produits Chimiques et Engrais has now started work in its factories at Feuchy les Arras (Pas de Calais), which includes a sulphuric-acid plant, a nitric-acid plant, and a factory for the manufacture of Phosphazote, a synthetic fertiliser containing 11 to 12 per cent. of nitrogen as urea, and 11 to 12 per cent. of water-soluble phosphoric acid. The urea is manufactured under licence by the process owned by the Société des Produits Azotés, and it is hoped to produce 12,000 tons of Phosphazote annually.

EDITORIAL

THE story which Mr. W. A. Davis tells us about Natural Indigo makes unsatisfactory, even melancholy, reading. The competition between the natural and the synthetic makes a different impression on each individual. We confess that for our part we are not free from prejudice; if the synthetic product is better, more uniform or distinctly cheaper than the natural we adopt it; on the other hand, if, as is the case with indigo, the natural product be as good or even better, as uniform and as cheap, we much prefer it. We dislike, quite unreasonably we know, to distil coal and perform a number of difficult operations in autoclaves and other instruments in a modern factory, and in a place like Huddersfield or Manchester, if the product can be efficiently made in India or Assam by the action of the sun on some living plant. We have sympathy with the planter who says, "I have not toiled, but take what God has made." Natural indigo has traditions, it calls up remembrances of nabobs and ryots, of Quakers in Lamb's Essays, of Clive and Warren Hastings. To waste coal, costing we do not know how many shillings a ton, and involving long and dangerous hours in a coal-mine, is not to be compared to the cultivation of a plantation by dusky natives in the sultry climes of India. And how mortifying is the end of the rivalry! A number of chemists make the synthetic indigo to their satisfaction, others, Mr. Davis being the leader, show how the yield of indigo can be increased, the quality improved, uniformity ensured, a lucrative trade organised and large areas of land maintained in a state of cultivation, even prosperity. And then, just as victory is within their grasp the horrid fates rob them of their reward. If there were some scientific or economic facts which meant that the natural indigo had no prospect of competing successfully with the synthetic we should say but little. But that a rather sentimental, and perhaps an unreasonable, unrest should involve the districts in such social and financial chaos as to end an industry which has flourished for centuries just as the cure for its troubles has been cleverly discovered, is too foolish and unkind. We have no recent news of the indigo plantations of Bihar. Are they now derelict? [illegible]

Virginia we saw many things which interested us deeply, and which we shall long retain in our memories. One of these was an area of many square miles of land once producing cotton, tobacco and maize, but now sparsely inhabited, covered with young and nearly useless trees, underwood and bushes, where here and there the wily negro in secret pursues the nearly equally wily turkey. It is a pity to see cultivation replaced by desolation; this has been the fate of some part of Virginia, and may well be the fate of Bihar.

* * *

The British Empire Exhibition at Wembley is nearing completion, and chemists, we think, will be very much interested in the exhibits of the chemical manufacturers, in the scientific exhibit, and in the book now being prepared to show the present state of chemical knowledge, dealing specially with the important contributions by British chemists during this century. These three pieces of work represent the labours of many chemists during many months. They have devoted valuable time to these projects, and have toiled at them at both convenient and inconvenient hours; they have done this without any hope of reward, cheerfully undertaking and performing the task, partly from a love of the science and partly from a high sense of duty. We owe them a great debt of gratitude. Particulars of the exhibits of chemical manufacturers will very shortly be available. From the preliminary list, which is by no means complete, it seems that the heavy chemicals, dyestuffs, fine chemicals, gas and intermediates, soaps, cosmetics, perfumes, polishes, varnishes, paints, tar products and drugs will be very well represented. It is too early to judge of the enthusiasm of the millions who are expected to visit this Exhibition, but if the other features are organised with the same care and assiduity as the chemical exhibits, the success of the Exhibition is assured.

* * *

The pamphlets which have been prepared for the edification of the non-scientific [illegible]

be made of most fascinating interest to an unscientific body of readers, and that a great deal of it can be explained in very simple language. Easy reading is, of course, hard writing, and our own experience satisfies us that some writers find it a very laborious task to provide matter which is easy reading. What has surprised us somewhat is the extent to which some readers are exasperated by the elementary articles on chemistry which have occasionally appeared in our columns. There is hardly any journal circulating in this country, except our own, which every now and then makes a deliberate effort to publish a chemical article which may be easily read by an accountant or a barrister-at-law whose only chemical knowledge is an association with a chemical company. We have recently received abundant, well-meant and sincere criticism from learned readers, who appear to us to forget that they belong to the distinguished and highly educated minority, and that they are in the possession of much information which a number of less fortunate individuals lack. A journal, so it seems to us, will hardly ever be read through from cover to cover by any one individual. The readers of the *Times* include many to whom fashion notes, company news, racing news, film news and musical news are of entire indifference. They do not complain, they merely turn on to the leading articles, or the foreign news or the golf news. We do not know whether we have misconceived the idea of a scientific weekly journal, but our ambition is that each week every reader will find something of interest. That each week the reader will find a good deal which does not make any appeal we fully expect. The Society of Chemical Industry has an opportunity of doing its small share in bringing chemistry home to the people of this country. It has been of great use in organising, and to some extent financing the British Empire Exhibition publications we have mentioned. Its Annual Meetings make a considerable item in the publicity which chemistry needs; we trust that the patience of our readers will enable a little to be done in this *Journal* to diffuse elementary chemical knowledge.

* * *

At one time or another few can escape the necessity for facing some problem connected with evaporating and drying, often under conditions of great discomfort, conditions that too often resemble, in their unreasonableness, the mediæval request for gowns made out of giant's beards. Mr. Ure, whose interesting article on evaporating we publish in this issue, is troubled with no such limitations, for the problems he discusses are confined to the calmer realms of chemical engineering. We are glad to draw attention to Mr. Ure's article on "Evaporating and Drying Plant," of which the part devoted to Drying Plant will appear in a later issue, and we announce that we have arranged for him to contribute several other articles dealing with various important classes of plant used in the chemical and related industries. Such articles fill a gap in the literature and it is our hope that they will be widely read and commented upon.

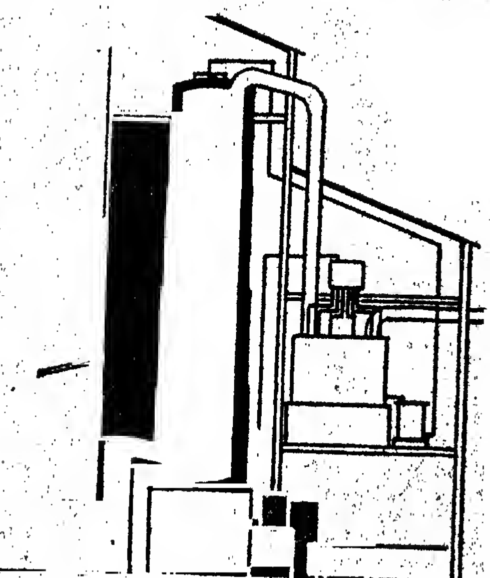
EVAPORATING AND DRYING PLANT

PART I

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

On account of its very extensive employment in the chemical industry, evaporation, the removal by vaporisation of a comparatively valueless non-volatile material from a substance, is of very great importance both to the chemist and to the engineer, and much study has been given to the problem of the development of plant for this purpose.

The heat required for vaporisation may be supplied to the substance directly, or indirectly, through a boundary wall. Brine solution is often concentrated directly by exposure to the sun's rays. Direct heating is also frequently employed in modern sulphuric-acid concentration-plant as represented by the cascade, Kessler and Gaillard types. In the

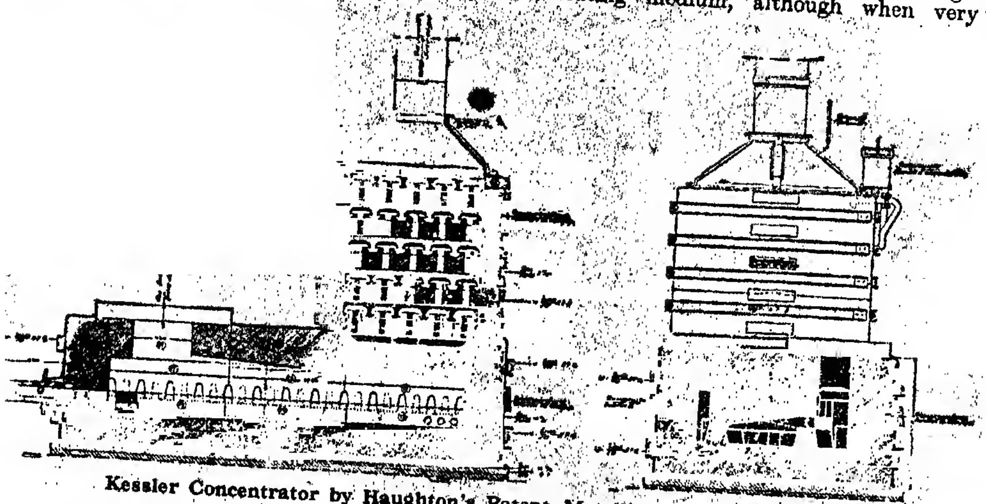


Gaillard Concentrator

FIG. 1

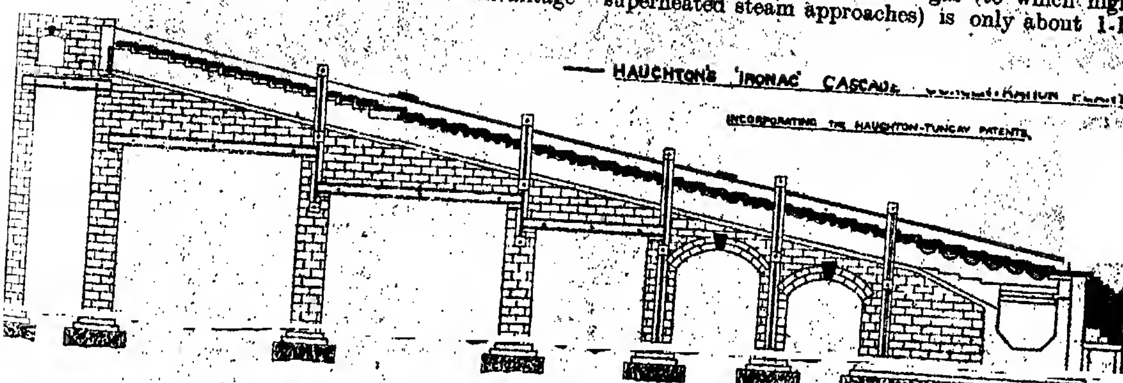
last-named plant, illustrated in Fig. 1, the sulphuric acid is admitted in the form of a fine spray at the top of a large vertical tower, whilst burning gases from a producer enter at the bottom. The concentrated acid collects at the bottom, and the products of combustion, together with the vapour evolved, leave at the top of the tower, and, after passing through a recuperator and scrubber, to remove any sulphuric acid which they may contain, are discharged into the atmosphere. In the Kessler plant, Fig. 2, hot gases from the producer pass over the surface of the concentrated liquor and then ascend a short tower provided with a number of trays of sulphuric acid of gradually increasing [illegible]on,

through which the flue gases bubble. The weak liquor is fed into the top of the tower near the exit pipe for the waste gases, which are again freed of acid before being liberated from the plant. The concentrated liquor outlet is at the bottom of the plant near the entry for hot gas. The cascade plant was one of the earliest forms of acid-concentration



Kessler Concentrator by Haughton's Patent Metallic Packing Co., Ltd.
FIG. 2

plant, and consists of a series of pans placed in échelon formation. The weak acid is admitted to the top pan and flows gradually downwards. The lower pans are heated by radiation and flue gases from a furnace and the upper pans by flue gases only. Although an efficient means of supplying heat to a substance, this method suffers from the disadvantage



Haughton's Cascade Concentrator
FIG. 3

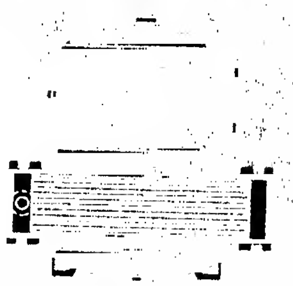
that the resulting product is usually contaminated with dirt obtained from the heating medium.

The supply of heat to the material through a metal wall is the method most commonly adopted in evaporator practice. When the plant is fire-heated, the heat is carried to the metal surface by radiation or convection. Here the main resistance to heat flow through the metal is the thin film of cold gas on the outer surface of the metal. In a very large number of evaporators the heat is brought to the metal container by means of a vapour or hot liquid which flows across one surface of the dividing wall, the liquid to be concentrated being in contact with the other surface. Steam is generally the heating medium, although when very high temperatures are required, and direct firing is impossible on account of the liability to burn the material, oil heating is adopted. High temperatures of evaporation cannot be economically obtained by using superheated steam, as it has been found that the heat transference from a gas (to which highly superheated steam approaches) is only about 1-100 of the heat capable of being transferred by a vapour at or near its saturation point, hence the adoption of oil as a heat-carrying medium when high temperatures are required.

TYPES OF EVAPORATORS

Evaporators using steam as the heating medium

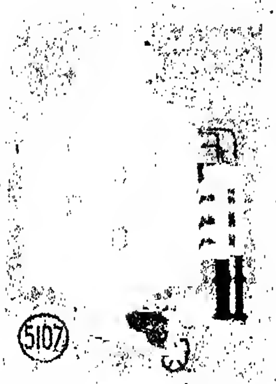
having a submerged heating element and those working on the film principle. Evaporators of the first group may be further subdivided into four types. In the first type, the heating element consists of a number of horizontal tubes placed inside a shell, which may be cylindrical, with axis vertical or



Horizontal Tube Evaporator by J. P. Devine Co.

FIG. 4

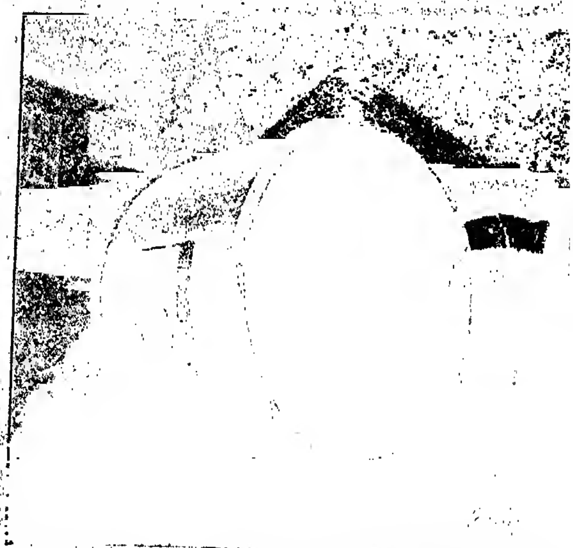
horizontal, or have the form of a rectangular box. The steam passes through the tubes, which are completely submerged in the liquor to be concentrated. It is claimed for this arrangement that it permits of quick cleaning and removal of the tubes when repairs are necessary, and that it gives an efficient steam circulation and allows of provision being made for the removal of condensed steam and non-condensable gases. Sometimes coils are used instead of straight tubes, as illustrated in Fig. 5.



Coil Evaporator by Manlove, Alliott and Co., Ltd.

FIG. 5

Had the next type been realisable in practice it would have consisted of horizontal tubes filled with liquid, the steam surrounding the tubes. The difficulty experienced with this type lies in the removal of the vapour, without the liquid, from the tubes. In the third type the tubes are vertical and contain the steam, whilst submerged in the liquor to be concentrated. The tubes are connected at top and bottom to two headers, which serve for the introduction of the steam and the removal of the condensate, respectively. These headers, however, interfere with the circulation of the liquid being heated, and so reduce the heat transference coefficient. This type is being discarded in favour of the fourth type, which is sometimes referred to as the standard evaporator. Again, the tubes are vertical, but in this case the liquid flows through the tubes and the steam surrounds them. This permits of a neat arrangement in the evaporator, as the heating element is usually formed of the lowest section of the shell, which is fitted with a tube plate at either end into which the tubes are fixed. An illustration of such a heating element is given in Fig. 6. The steam is admitted through an

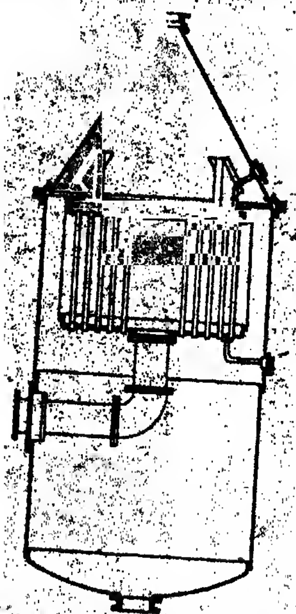


Heating Element used in G. Scott and Son's Evaporator

FIG. 6

opening in the cylindrical portion of the element, and the tubes are specially arranged to ensure equal distribution of the steam over the whole heating surface. To maintain a rapid circulation of the liquid through the tubes, and thus obtain a high rate of heat transference, downcomer tubes are fitted. Sometimes these are placed outside the heating element; in other cases they are situated at regular intervals among the smaller tubes, an arrangement favoured by G. Scott & Son. Devine, as well as Blair, Campbell and McLean, adopts the central tube type of downcomer, sometimes insulated from the heating medium by an air gap, whilst Manlove, Alliott & Co. and Fullerton, Hodgart and Barclay employ a side downcomer, formed by the cylindrical shell and a flat surface on the heating element. A modification of this type of heating element is known as the basket type and is illustrated in Fig. 7. In this case the heating element consists of a number of parallel tubes fixed to the tube plates attached to the ends of a cylinder, which is considerably smaller in diameter than the evaporator shell, and usually rests on a series of lugs attached thereto. The steam is introduced to the

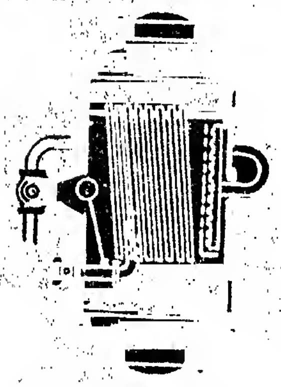
which is fixed to the centre of the upper tube plate, and passes out, either through the top or the side of the outer shell, whilst a smaller tube attached to the outer wall of the heater at its lowest point, and passing through the shell of the evaporator, serves to remove the condensed steam. With this



Basket Type Evaporator by J. P. Devine Co.
FIG. 7

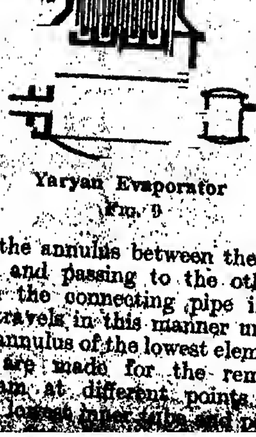
type of heater the annulus formed between the heater and the outer shell acts as the downcomer. Advantages of this type of heater are that it can be removed bodily from the evaporator for cleaning and repair, and that all the heat liberated by the condensation of the steam is transferred to the liquid. All these types of evaporators are provided with a large vapour space above the heating element; it is stated that in large evaporators this space can be considerably increased without materially affecting the radiation losses from the outer surfaces.

M. Paul Kestner, of Paris, invented the film type of evaporator, and many evaporators have since been designed working on this principle. In such plants the liquid being heated is maintained as a thin film on the heating surface. Evaporators of this group can also be subdivided into four types. In the first of these, the tubes are horizontal, the liquor to be concentrated forming a thin film on the outside. The only modern representative of this type is the Lillie evaporator, shown diagrammatically in Fig. 8. The steam is admitted to a steam chest at one end of the evaporator from which it enters a series of parallel horizontal tubes, closed at one end, except for small holes through which the non-condensable gases may escape into the surrounding chamber, whilst the condensed steam runs back to, and is drained away from, the bottom of the steam chest. The liquor to be concentrated is sprayed over these tubes and the concentrate is collected at the bottom of the chamber surrounding them.



Lillie Evaporator
FIG. 8

Several firms manufacture evaporators belonging to the second type, in which horizontal tubes are surrounded by the heating medium, and the liquid to be concentrated passes inside. The Kestner horizontal evaporator belonging to this class is made up of a number of pairs of concentric tubes, placed one above the other, the inner tubes being held in position by stuffing boxes attached to the ends of the outer tubes, whilst the outer end of the inner tube is coupled to the one immediately below it by a U bend. The alternate ends of the outer tubes are connected together by T pieces.



Yaryan Evaporator
FIG. 9

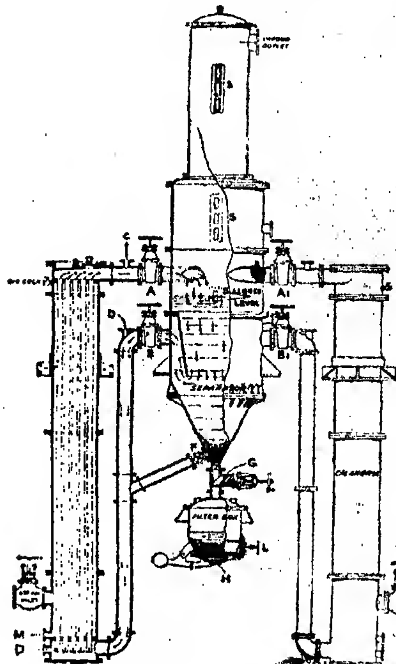
Steam enters the annulus between the top two concentric tubes, and passing to the other end flows down through the connecting pipe into the next annulus, and travels in this manner until it reaches the end of the annulus of the lowest element. Suitable arrangements are made for the removal of the condensed steam at different points. The liquor flows along the lowest inner tube and passes through

the U bend to the one immediately above, thus producing counter-flow to the steam. During its passage through the tubes some of the liquor flashes into vapour and passes through as little pistons of liquid with vapour between.

In the Yaryan evaporator, shown in Fig. 9, the horizontal tubes for carrying the liquor are coupled at the end so as to form a sinuous passage of considerable length. Several of these nests of tubes are contained in an outer shell, to which the heating vapour is admitted, the condensed vapour being drained off at the lowest point. In this plant the liquor enters at the top of he nest of tubes, and flowing downwards is discharged into a separate chamber, where the removal of the vapour from the concentrated liquor takes place.

An approximation to the next type is obtained when in type 3 of the first group the liquid level is lowered so that a considerable portion of the tubes extend into the tube space. Then the uncovered portion of the tubes become coated with a thin film of liquid obtained from the froth.

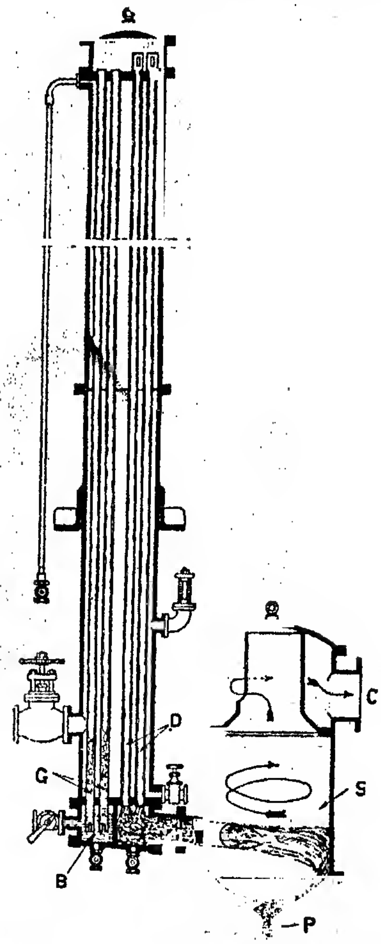
A recent patent described an evaporator consisting of a number of hollow steam-heated cylinders mounted with their axes vertical. The liquor was applied to the outer surface of one cylinder as a thin layer, and was transferred from one cylinder to another by the



Kestner Evaporator—Salting Type

FIG. 10

rotation of one cylinder against another, the final concentrate being removed by a scraper. This might be classified as an evaporator of the vertical outside film type, although its action is analogous to that of a drum dryer. The Kestner vertical climbing film evaporator is a typical example of the last type of this group. In this the liquid ascends inside a series of vertical tubes, which are surrounded by the heating medium. M. Kestner



Kestner Patent Falling Film Evaporator

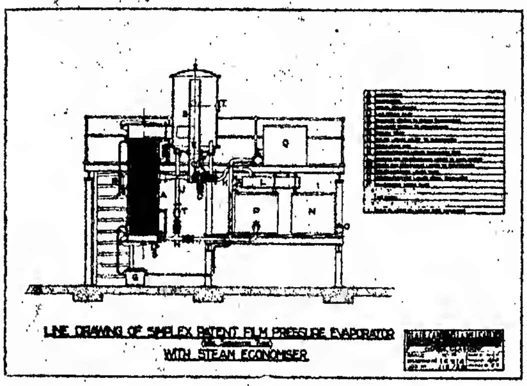
FIG. 11

claims that with this type of evaporator the vaporisation of the liquid at the bottom of the tube produces a column of rapidly moving vapour within the tube, which draws up a thin film of the liquid being concentrated over the surface of the tube. Other writers on the subject maintain that the action is analogous to that of an air-lift pump, namely, a series of vapour spaces alternating with pistons of the liquor. In this plant tubes of 7 m. in length and 5 cm. in diameter are used, whereas the firm of Blair, Campbell and McLean, which also manufactures a vertical film evaporator does not employ very long tubes.

HEAT TRANSFERENCE

To deal with entrainment or frothing in evaporators of the first group a large vapour space i

provided above the free surface of the liquid, but in evaporators of the film variety the separation of the vapour from the liquor is generally effected in another vessel termed the separator. In this vessel advantage is taken of the high velocity of the liquid, usually about 10 feet per second, to produce separation by centrifugal action, and to cause this the liquor is usually discharged into the separator tangentially to the surface of the vessel. The coefficient of heat transfer in the case of a condensing vapour transmitting its heat through a boundary wall to a boiling liquid is influenced by the temperature difference between the vapour and the liquid, the density of the liquid and its viscosity, and the cleanliness of the boundary surfaces. Now, with a steam supply at a given pressure, the only way to increase the temperature difference between the vapour and the liquid is to lower the boiling point of the latter, and as the boiling point is a function of the pressure existing at the surface of the liquid this has led to the employment of evaporators working under vacuum. During evaporation, as the concentration rises, so will the boiling point of the liquid, and therefore the rate of



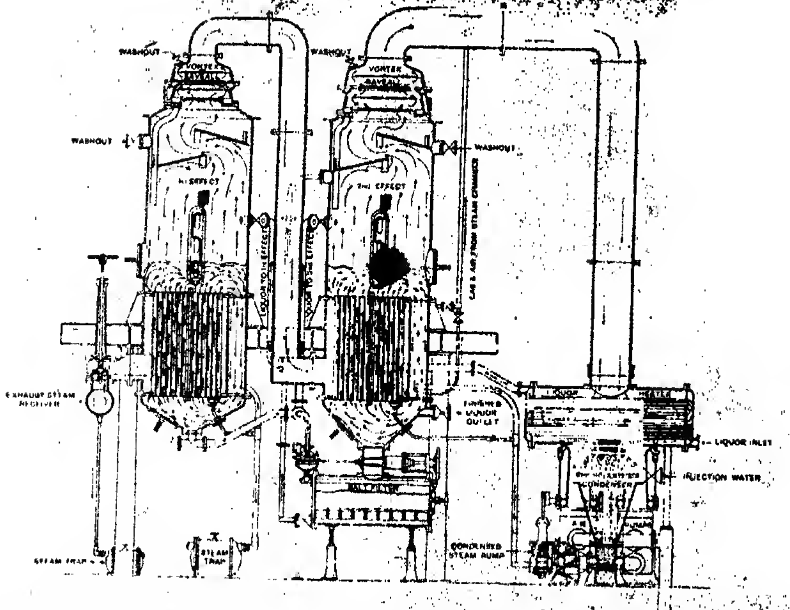
Simplex Film Pressure Evaporator by Blair, Campbell & McLean, Ltd.

FIG. 12

heat transfer will fall off. The reduction of the boiling point is also advantageous and even compulsory when evaporators are required to handle delicate liquids. In determining the vacuum to be applied in an evaporator of the first group, when dealing with a delicate substance it must be remembered that the pressure at a point will increase with its depth below the free surface, and therefore such a vacuum will be required as will prevent destruction of the material in contact with the lowest point of the heating element. The velocities of the vapour and liquid over the surfaces of the tubes affect inversely the thickness of the films covering these surfaces and therefore the rate of heat transfer. Also the greater the velocity of the liquid the shorter is its time of contact with the heating surface, and there is less likelihood of its being damaged by being raised to too high a temperature. With rapid circulation, such as is obtained in the film type of evaporator, delicate liquids can be concentrated at atmospheric pressure without injury. The rapid movement of the liquor inside the tube tends to prevent the formation of scale, and thus maintains the high coefficient of heat transfer, which may amount to 3000 calories per square metre per hour per degree C., a figure very difficult to exceed in general practice. When solids are liable to be deposited upon the heating surface by the liquor being concentrated, many devices are resorted to to maintain the heat transmission efficiency of the plant. In addition to the employment of high velocities sharp gritty material is added to the liquor which, being carried round by the stream, tends to remove any scale which may be deposited. The basket type of evaporator has the advantage that the basket can be removed to clean off the scale. When badly scaling material is being treated, two baskets are frequently employed, one in operation in the plant and the other undergoing cleaning and repair, thus minimising the delay caused through cleaning. In other cases an extra evaporator, or calandra, is installed and connexions are so arranged that any of the evaporators or calandras in the set can be easily isolated for cleaning or repairs.

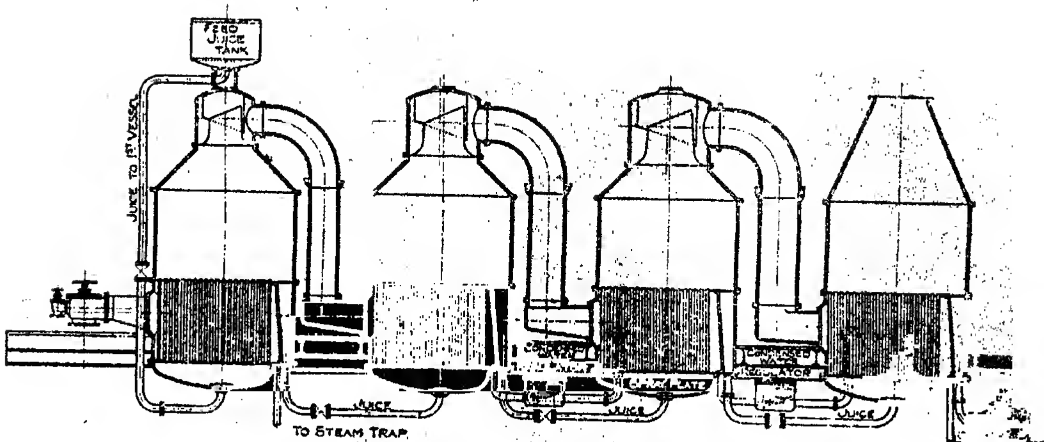
The evaporation per square metre per hour from the free surface of the liquid is another important factor, especially in plants of the submerged heating element type, for upon this factor depends to a large extent the vapour space required. This factor is a very variable one, and depends largely upon the nature of the material, and the conditions under which concentration is effected. From figures derived by Professor Hinchley from data supplied by G. Scott and Sons, Ltd., one finds such rates of evaporation as 43 kg. per sq. metre per hour for malt extracts, 78 kg. per sq. metre per hour for caustic soda liquors, etc., although an evaporation of 2700 kg. per hour per sq. metre has been attained in certain instances. Generally the higher the rate, the greater the trouble likely to be experienced from entrainment and frothing. Some liquors when heated foam or froth freely, and various devices have been adopted to overcome this trouble. With the submerged heater type of plant, the customary procedure when handling a foam-forming liquid is to lower the liquid level until part of the heating element projects above the free surface into the vapour space. In this way the froth rising from the liquid is further heated, thus bursting the bubbles, and forming drops of liquid which fall back into the original mass.

Sometimes this trouble is overcome by reducing the rate of evaporation from the free surface of the liquid, but this is not an infallible remedy for foaming, as certain liquids have been found to "boil off" even under gentle boiling. A crude device and one never recommended by evaporator manufacturers, is to cover the free surface with a thin film of oil, but such a method has decided limitations. Other factors which affect the foaming propensities of liquids include their concentration, the working pressure inside the plant, and the pressure of the steam admitted to the heating element. When concentrating a solution of sodium tungstate and



Caustic-Soda Soap Lye Evaporator by Fullerton, Hodgart & Barclay, Ltd.

FIG. 13.



Quadruple Effect Evaporator by G. Fletcher & Co., Ltd.

FIG. 14.

sodium carbonate which frothed badly, even under gentle boiling, Manlove, Alliott and Co., Ltd., found that when a certain concentration had been attained this trouble completely disappeared and did not return. The small quantity of liquid actually in contact with the heating surface and its rapid rate of circulation tend to eliminate foaming troubles in evaporators of the film type, nevertheless makers of both types of evaporators fit saveall devices at the entrance to the outlet pipes of the plant to remove any liquid which may be brought to the outlet either by entrainment or foaming.

Materials used in the construction of evaporators largely depend upon the chemical properties of the substances to be concentrated. The tubes of evaporators are commonly made of mild steel, but in cases where this has proved unsuitable, cast iron, copper, phosphor bronze or lead tubes have been installed. The casings of evaporators and separators are usually made of cast iron, mild steel or copper. Where [illegible]

of product is of first consideration as in the production of distilled water, it is customary to cover with a thick coating of tin, generally deposited electrolytically, all internal surfaces which come in contact with the liquor and the finished product.

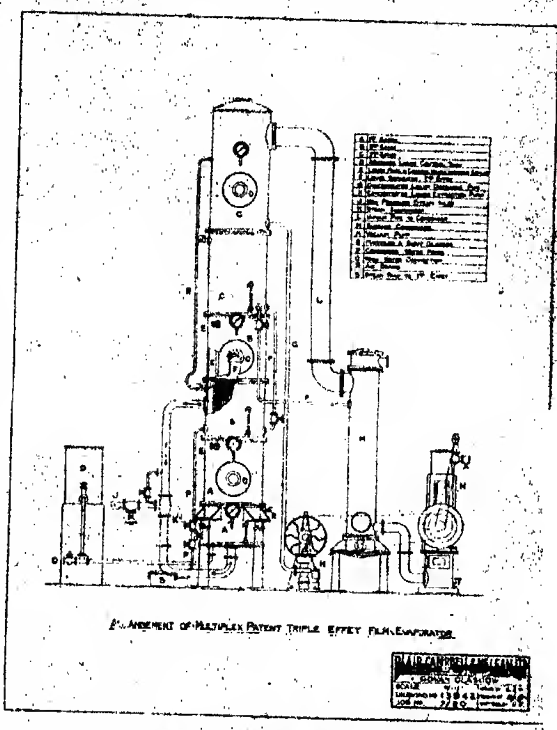
Single and Multiple Effect Evaporators

If waste steam at suitable pressure is available, the waste steam at suitable pressure is available, the custom is to install single effect evaporators, as here the heat is obtained at the minimum cost and the plant involves the minimum capital outlay. In factories where it is necessary to concentrate two different solutions having different boiling points, such as caustic soda and soap lye, it is customary to arrange the plant in the following manner. Two single effect evaporators are used, in the first of which the weak caustic soda solution is concentrated by heat obtained from live steam. The vapour evolved during this process, instead of going to a pre-heater or condenser, is passed into the steam space of the second evaporator which is fed with weak soap lye. This system is illustrated in Fig. 13, and provided one had a number of substances having a suitable series of gradually diminishing boiling points, the principle could be equally well applied, so that each substance would be concentrated in its own evaporator, the heat required for its concentration being obtained from the vapour evolved from the substance having the next higher boiling temperature. This is really a combination of simple and multiple effect evaporation, the steam being used as in the multiple effect plant and the liquors as in the single effect evaporator.

Fig. 12 gives a sectional elevation of a quadruple effect evaporator working on the purely multiple effect principle. As will be seen the steam and the liquor are admitted to their respective compartments in the first effect. The vapour generated by the passage of the liquid through the tubes collects in the vapour space and after passing through the saveall is led into the heating space of the second effect. The liquor rising through the tubes of the first effect flows into the side down-take, which is sealed, and is carried into the liquor space of the second effect. Here the pressure in the vapour space is less than that existing in the vapour space of the first effect, and therefore steam will be flashed off from this hot liquor, and a further heat transference will take place between the vapour in the heating element and the liquor, which will generate more steam from the latter.

This steam passes into the heating space of the third effect whilst the hot liquor flows in a similar manner into the corresponding liquor space. Here, due to a further pressure reduction, more steam is generated in a similar manner to that described above, and then both vapour and hot liquor pass to the heating and liquor spaces of the fourth effect. The steam evolved in this effect by a repetition of the process is withdrawn through a pre-heater or condenser by a pump which maintains the requisite vacuum in the last effect. The liquor at the required concentration leaves the last effect for the next stage in the process. It will be observed that the condensed steam from the second and third effects is led into steam traps fitted with steam spaces connected to the heating chambers of the third and fourth effects respectively, thus permitting steam flashed off by reduction in pressure to be utilised in those heaters. Multiple effect evaporation is resorted to in plants of the submerged heater and film types. In the plant described it will be observed that the flow of liquid takes place in the same direction as the flow of the heat-supplying medium, and such plants are said to work on the parallel current system. If the weak liquor entered the plant at the last effect, the concentrated liquor being discharged from the first, whilst the steam flow remained as before, the plant would operate on the counter-current system.

Should each effect be fed independently, as in plants handling different liquids, the operation would be termed parallel feed. An analysis by Weber of these three methods of working, shows that if the liquor is fed into the evaporators below a critical temperature the steam consumption is greatest in the case of parallel current and least in the counter-current type, but with a feed above the critical temperature the steam consumption is greatest with counter-current operation and least in parallel flow. The ratio of the evaporation per lb. of steam used is greatest with the parallel current, and least with the counter current, with a feed below the critical temperature and least in the parallel current flow



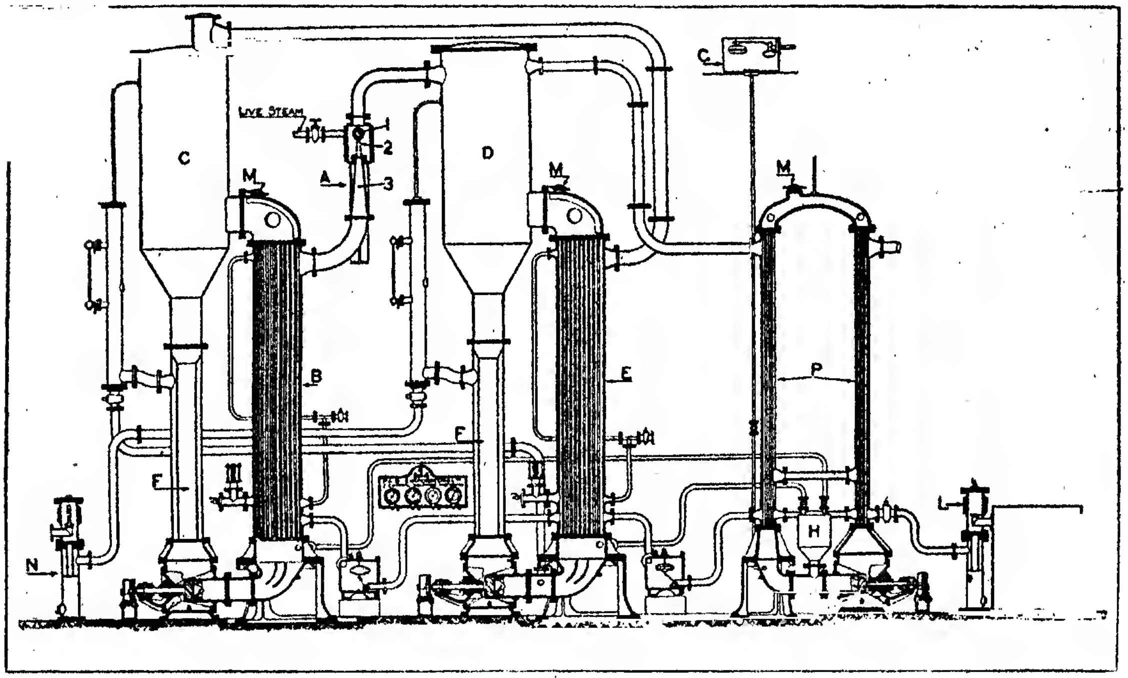
Multiplex Evaporator by Blair, Campbell and McLean, Ltd.

Fig. 15

and greatest in the counter current flow when the feed is above the critical temperature. As one would expect, the amount of vapour to be condensed from the last effect gradually rises in the counter-current and parallel feed types as the temperature of the feed is raised. Under a critical temperature, the amount is least in the case of a counter current flow, but above a critical temperature it ultimately becomes the greatest of all the types. Parallel current places a constant load on the condensing plant irrespective of the feed temperature. Another method of passing the liquor through the evaporators, adopted by G. Scott and Sons, Ltd., especially when the concentrated liquor has for various reasons to leave the plant at a higher temperature than the boiling temperature, consists in feeding the weak liquor into the first effect, passing it from this effect into the third and then into the second, from which it is discharged from the plant.

In Blair Campbell and McLean's multiplex film evaporator, shown in Fig. 15, the liquor is fed by gravity into the first effect which is heated by live steam, which may consist of exhaust steam at a pressure from zero to 5 lb. per square inch. The liquor and the vapour generated therefrom by its passage through the heater tubes, is projected against a baffle plate and then passes through an opening into a separator. After separation the liquid collects on the upper surface of the baffle, whilst the vapour passes into the [illegible] space of the next effect. A pipe descending from the liquor space of the second effect to the baffle plate of the first, serves to convey the liquor to the liquor space of the second effect, where the pressure is less than in the separator chamber of the first effect. Rising through the tubes of this effect more vapour is produced. Again, the liquid and vapour are projected against the baffle plate on the top of this effect, and then enters the second separating chamber. After separation the vapour enters the heating space, and the liquid enters the liquor space of the third effect in the manner described above. When the vapour and concentrated liquor, after impinging on the third baffle plate, enter the third separating chamber, the vapour is removed through a suitable preheater and condensing plant, and the concentrated liquor is withdrawn from the top of the third baffle plate. Sufficient vacuum is maintained in the separator of the third effect to ensure successful working of the plant. The separating chambers are so dimensioned that the short tubes of the heaters can be easily cleaned or removed if repairs are required. The whole plant is compact, requiring little floor space and presenting a minimum surface through which heat may be lost by radiation.

Multiple effect evaporators are generally used when only high-pressure steam is available, and plants of this type have been manufactured having 12 effects. With such a plant usually engaged on water distillation, the initial steam pressure requires to be generally in the neighbourhood of 150 lb. per square inch for successful working. Multiple effect evaporators, however, usually consist of triple and quadruple effect plants, and it is stated that with



Prache Bouillon Evaporator

FIG. 16

certain types of plant every 1 lb. of steam supplied will evaporate 1·66 lb. of water in a double effect, 2·75 lb. of water in a triple effect, and 3·33 lb. of water in a quadruple effect. The actual cost of evaporation taking the cost in a single effect plant as unity works out at 0·552 for a double effect, 0·406 for a triple effect, and 0·276 for a quadruple effect. At first sight, therefore, it would appear that multiple effect evaporation is an economy, but one has to remember that such plants involve a much larger capital outlay than in the single effect plant, and also necessitate a higher initial steam pressure to ensure the requisite temperature drop between each effect.

Thermo-compression

Recently considerable attention has been directed to rendering the low-pressure steam evolved from the liquor suitable for re-admission to the heating space. The method by which this can be carried out consists in removing the low-pressure steam from the ebullition chamber, and compressing it to such a pressure that it can be again admitted to the heating space. When this is done evaporation will take place with an expenditure of energy equal to that supplied by the compressor, the latent heat present in the initial steam having been transferred to the low pressure steam which it has produced. This seems to point to an economical method of evaporation, provided a suitable method of compression is available. Two types of compressors have been tried, the pump compressor and the injector compressor. Of these compressors the latter is the type adopted by Prache Bouillon, Kestner and Blair Campbell and McLean in their evaporators working on this system. In this type the steam consumption required to operate the compressor is largely increased, the greater the difference in temperature to be maintained between the steam and the liquor. This necessitates that evaporators working on this system should only have a small temperature difference between the steam and the liquor, usually about 6°. With such a small temperature drop, special attention must be given to the prevention of scale on the tubes, as this causes the heat transference to fall off rapidly. In the Prache Bouillon Evaporator, illustrated in Fig. 16, the heating element consists of a series of vertical or inclined tubes through which the liquor is circulated mechanically by a pump. Sufficient pressure is maintained in the tubes to prevent the formation of large bubbles of steam, until the liquor is discharged into the separator, when, on the reduction of this pressure the steam is flashed off. A portion of the steam from the second effect is carried to the preheater, and the remainder passes through the compressor, and is then discharged into the heating space of the first effect, the vapour produced in the first effect being admitted to the heating space of the second. In this plant there is a three degree temperature drop in each effect. To keep the tubes clean, finely ground quartz is introduced into the evaporator and circulated with the liquor. The makers claim an evaporation of 6½ lb. of distilled water per lb. of live steam used.

SOME PAGES FROM THE STORY OF INDIGO

By W. A. DAVIS, B.Sc., A.C.G.I.

The Decline of the Natural Indigo Industry

(Continued)

When war broke out, the supplies of synthetic indigotin from Germany being cut off, a serious shortage of indigo was felt which led to an enormous rise in the price of indigo. Indian indigo which had been selling at Rs. 250-260 per cwt. jumped to about 1000 Rs., this level being maintained during the first two years of war. In India arrangements were immediately made to increase the area under indigo, and in 1916-1917 the acreage was 756,400—nearly a four-fold increase.

Whilst on his way home from a meeting of the British Association in Australia, Prof. H. E. Armstrong, who had always been keenly interested in the struggle between natural and synthetic indigo, sent a letter to the leading Calcutta paper, the *Statesman*, urging the necessity of renewed research. Considerable interest was aroused and in 1915 an official conference was held at Delhi and the matter was referred to the India Office. After giving full consideration to the issues, the India Office made certain recommendations and eventually an understanding was arrived at with the Bihar planters. Prof. Armstrong acted as scientific adviser to the India Office, and as a result of his invitation the author went out to India in May, 1916. A small cess was levied on all indigo exported from India to pay the costs of research, so that the indigo producers largely paid the costs of the investigation.

Feeling very doubtful, like most chemists at the time, of the future of natural indigo, Prof. Armstrong stipulated that at first my engagement should be for one year, during which time I could more fully look into the question. In the course of this year many rather surprising facts emerged which led me to consider that, providing certain conditions were realised, natural indigo could still put up a good fight. I, therefore, recommended the extension of the work for a period of five years. In the first place, after a careful examination of all the facts available, it appeared clear that the issue was pre-eminently an agricultural one and that the main problem was to ensure the satisfactory growth of the indigo plant. Some years earlier a greatly improved type of indigo plant had been introduced into India from Java, where it had been developed by the Dutch indigo research station. The Java variety, *Indigofera arrecta*, when introduced into India gave such phenomenal returns as compared with the old *Sumatrana* plant, that the planters, who had been going through a very thin time, thought their salvation had come.* The old plant had given about 5 seers (10 lb.) of cake indigo per acre, but with the new plant yields of 20 to 40 seers were obtained for several successive years on many

* See especially D. J. Reid, "Ten Years' Practical Experience with Java Indigo in Bihar" (*Ag. J. India*, 1917, 12, Part I), and Indigo Publications Nos. 1, 2, 4 and 6; also Prof. H. E. Armstrong's paper, "Soil Deficiencies in India," read before the Royal Society of Arts in May, 1919.

estates. Several planters who had taken up the Java plant on the large scale had made very substantial fortunes in spite of the competition of synthetic indigotin. The very low yield of indigo per acre with the old *Sumatrana* plant had meant that the costs of sowing, cultivation, manufacture and overhead charges were unduly high in proportion to the return. From an examination of actual working expenses at several factories it became clear that by increasing the yield of indigo per acre the cost of production could be so greatly diminished as to make it possible to compete easily with syntheti[illegible] indigotin. The following table shows this :—

Yield of indigo per acre Seers		Cost of production of 1 maund* of indigo with charges Rs. 40 per acre
5	..	320
10	..	160
20	..	80
30	..	53
40	..	40

1 Factory maund = ⅔ cwt. = 74·66 lb.
1 Seer = 1/40 maund = nearly 2 lb.

As was stated by Bernard Coventry, C.I.E., a large indigo planter who was largely responsible for the introduction of Java indigo and subsequently became agricultural adviser to the Government of India, "If we could grow the plant properly it would give at least 20 seers of indigo per bigha (0·87 acre), and with such a yield I would undertake to undersell synthetic indigo at practically any price."

The trouble was, when I arrived in India, that the Java plant which at first had given such extraordinary yields had largely ceased to do so, and the high hopes originally formed had in many cases been disappointed. On some estates big yields had been maintained for a few years, but in many cases after three or four years the yield rapidly fell off, and, what was even more serious, the plant failed to give seed. A mysterious disease, the so-called "wilt" disease of indigo, had appeared, neither fungal nor bacterial in origin, which was accompanied by a great falling-off in plant. Whereas the Java plant at first had given two, sometimes three, magnificent cuttings with a total yield of 200-300 maunds of plant of high quality in the season, in 1916 the yield had fallen to 50-70 maunds per acre. Only a single cutting, often a poor one at that, was obtained, and the yield of cake indigo had fallen from 30 to 40 seers to about 5 to 7 seers per acre.

Yield of indigo per acre

		Acres		Yield per acre cake indigo
1916-1917	..	80,600	..	15 [illegible] = 7½ seers
1917-1918	..	86,700	..	1[illegible] 6½ „
1918-1919	..	64,200	..	1[illegible] 5½ „

One of my first tasks, therefor[illegible] to make a thorough examination of the plant[illegible]tates : some 600 samples of soil were taken fro[illegible]any different estates and analysed. The resul[illegible] convinced me that the so-called "wilt" disc[illegible] was in reality due to soil starvation ; the soi[illegible] had become so impoverished by continuous stripping without any suitable manurial treatment that the plant could no longer obtain sufficient nutriment for proper growth.

The soils were very variable from place to place—as is usual in areas subject to annual flooding during the rains. In practically all places where the plant had failed badly there was a great deficiency of either phosphate or organic matter, often both, in the soil.

Systematic manurial trials were instituted and maintained during six years, both at the Agricultural Research Institute at Pusa and on numerous planters' estates. In many cases extraordinary increases of crop—both of indigo and the cold weather crops (oats, wheat)—were obtained by proper manurial treatment—either superphosphate alone or combined with green manure (sannai). In several cases poor soils which were practically useless for cropping gave yields of 15 maunds of oats per acre, whilst others gave a yield of 30 maunds after manuring as compared with 13 without. This side of the question has been dealt with in detail in my *Indigo Publications* issued by the Agricultural Department of India, and the story has been told in two papers read by Prof. Armstrong at the Royal Society of Arts in 1919 and 1922.

In my final report to the Government of India in 1922, I stated : "In my opinion the importance of proper manuring in N. Bihar cannot be over-estimated—it is the keynote to the prosperity of the indigo industry and ultimately of the ryots on small holdings who depend largely on special crops such as tobacco, chillies, grown on lands manured with indigo seet (the refuse plant obtained after steeping the indigo). Most planters' estates have been greatly impoverished by lack of proper manurial treatment, especially since the advent of the high-yielding Java variety of indigo which more rapidly strips the soil than other crops. The effect of proper manurial treatment is cumulative. By improving the yield of indigo from the present 50–75 maunds of green plant per acre up to 150–200 maunds (which actual planters' trials have shown to be possible) the output of indigo seet is doubled, and so a far more efficient manuring of *rabi* (cold weather) crops (cereals, tobacco, chillies, etc.) with correspondingly higher yields becomes possible. The value of the lands let out to the ryots for growing tobacco is also greatly increased. Lands which ordinarily would be let unmanured only for Rs. 20 per acre, are gladly taken after seeting, by ryots at a rental of Rs. 100 to 120 per acre. Increased profits from good yields of cold weather crops such as oats, wheat, mustard, tobacco, and the rental derived from lands let out to ryots, would go far towards bearing the expenses of indigo cultivation and increasing the possibility of competing with synthetic.

Thus, in one of the best worked and largest indigo concerns, after allowing for the profits from rabi crops, the actual cost of production of indigo has worked out recently at only Rs. 6 per maund, whilst it has been selling at Rs. 400 per maund or more. In fact, success in the future in competing with synthetic indigotin will depend as much on the increase in the profit from other crops by manurial treatment as from an increased yield of indigo itself."

Indigo Paste

One of the main reasons for the rapid success of synthetic indigotin was that the Germans made special efforts to meet the wants of the consumer. Natural indigo is a mixed product of ever varying composition, containing 40–70 per cent. of indigotin; it was necessary to have an analysis made of every chest at the time of sale, and it was sold in hard lumps which required a long and tedious grinding—often occupying a fortnight—to bring it to the necessary condition for use. Long before the manufacture of German indigotin, artificial alizarin had entirely superseded natural madder owing to the fact that whereas madder was a vegetable product of entirely inconstant value, alizarin could be supplied in paste form of definite guaranteed strength. The same principle was applied by the Germans to "Synthetic." It was sent out as a standardised paste containing 20 per cent. of indigotin, all ready for use; no grinding or mechanical preparation was necessary. Had the planters, when competition first began, put indigo on the market as a paste of standard strength natural indigo would probably not have been ruined. Prof. Armstrong had specially emphasised this point in his letter to the *Statesman*, and my first problem in India was to put on the market a stable paste of fixed composition comparable with the German.

Within a few weeks it was possible to send home a stabilised and standardised indigo paste. At this time, however, great difficulty was experienced in India in procuring suitable casks or drums, and the high shipping rate made it uneconomical to send home a material containing so much water—80 per cent. The inquiry was, therefore, continued in England and Mr. Reginald Brown undertook the task of grinding the cake indigo to paste, and stabilising the product. For the grinding, special machinery was soon found which enabled the cake to be reduced to a very fine paste form in a couple of hours, and stabilisation (the prevention of putrefactive changes) was ensured by the addition of a very small quantity of paranitraniline, which prevented the growth of fermentation organisms.

Natural indigo, in this form, possessed considerable advantages over the synthetic indigotin, particularly for woollen goods and heavy shades—it went much further than the synthetic material, and gave more agreeable tones and a fine bloom. The colour produced by the synthetic product has always lacked "soul." Natural indigo found a ready sale in this country, the quantity being limited only by the supplies of cake indigo which the planters were willing to send home; they were obtaining high prices in Japan.

The Attempt to Capture the Chinese Trade

It is a curious commentary on the old indigo industry that during 100 years' prosperity no attempt was made to capture the huge China market. In fact the existence of this market appeared generally unknown. Every man, woman and child in China wears an indigo-dyed garment. The Germans very soon realised the importance of this, and before the war China and Japan together took three-fifths of the whole of the synthetic indigo produced. The mass production so obtained by cheapening the product was undoubtedly the last nail in the coffin of Indian indigo. In January, 1918, I emphasised, in an article on the situation, the great importance of this, and wrote: "The prosperity of the Indian industry and its ability to compete with synthetic in the future will depend largely upon its being able to supply the Eastern markets. The British and American consumption is small by comparison."

Nothing was done, however, for nearly two years, although there was a good deal of talk. Towards the end of 1919, however, the newly formed Assam Indigo Company, of which I shall speak later, asked me to visit China and Japan on their behalf whilst I was returning home on short leave. I found that China and Japan wanted paste and paste only, and I ascertained their exact requirements. In 1920 and 1921 arrangements were made by Mr. Geoffrey Watson, of Moran and Co., the chief Indian indigo brokers, and the "Indian Marketing Agency, Ltd.," representing the Indigo planters of Bihar, to start making paste indigo in Calcutta for the Chinese market. A technical chemist was engaged by this organisation to direct the operations and the necessary machinery was obtained from home through Mr. Reginald Brown, for the purpose. This was the condition of affairs when I left India.

Development of the Business Organisation in India

In the old days one of the greatest difficulties the industry had to face was that the indigo sales were badly organised: in their endeavour to dispose of their indigo rapidly, so as to finance the next season's working, the planters cut each other's throats and sold their indigo in such a way that the market rapidly fell against them. A great step in advance was made by Mr. Geoffrey Watson in 1918-1919, when after many difficulties he was able to organise the majority of planters into a pool, by which the indigo sales were controlled and a fair selling price maintained. This pool of Bihar planters was known as the Indian Indigo Association, which in 1921 for trading purposes formed a separate company, the Indian Marketing Agency, Ltd. It was this company which undertook to prepare paste indigo in Calcutta.

The Introduction of Indigo Cultivation into Assam in Conjunction with Tea

When war broke out in 1914 and steps were taken to extend the cultivation in Bihar, the main difficulty was to obtain sufficient Java indigo seed. As already stated, soil deterioration in Bihar had reached such a pitch, that the plant, which had at first given seed abundantly, refused to give any on most estates or only a very small yield. Mr. Tunstall, Mycologist of the Tea Associati n, happened to be at Pusa in 1914. Hearing of the difficulty and having noticed that *wild indigo* grew most luxuriously in Assam, he obtained a small supply of seed and started growing indigo for seed. He found t at the Java indigo grew most luxuriantly,

and, what was then most important, gave extraordinary yields of very high quality seed—10·15 maunds per acre instead of $\frac{1}{2}$-2 maunds as in Bihar. He took up the cultivation of seed on the large scale, and other tea planters followed suit, and a very profitable indigo seed industry was developed which met all the wants of Bihar.

It was found that extraordinary yields of green plant were obtained—200·300 maunds an acre—as compared with 50-70 maunds at most Bihar factories—and the plant was unusually rich in indigotin. Encouraged by these results a small experimental factory was started at the Panchnoi Tea Estate in 1919, and this was shortly followed by the Assam Indigo Co., Ltd., a company formed to develop indigo on a larger scale. One of the assets of the natural indigo industry is that it gives a very large quantity of the highly valuable manure—seet—and this indigo seet has been found to be an ideal manure for tea (as it had been found to be for tobacco in Bihar). In this way a supply of manure for the tea crop—a very important question in Assam—could be very cheaply obtained and heavy outlay on artificial fertilisers avoided.

In my opinion the main hope of Indian indigo to combat synthetic indigotin lies in developing the production in unusually favourable yielding areas such as Assam. Bihar at the present time supplies only $\frac{1}{20}$th of the requirements of China and Japan and $\frac{1}{10}$th of the world's requirements. A sufficient increase in the production from Bihar seriously to stem the tide of the synthetic material is not to be anticipated even if suitable manuring were generally adopted, and progress in this direction is greatly handicapped by the present shortage and high cost of phosphatic manures, although the supply of these to Bihar planters has been organised by the Indian Marketing Agency. The area under indigo in Bihar has recently been diminished by agrarian difficulties in Champaran, and the spread of the more profitable sugar-cane cultivation. With a good extraction, the very high yields of fine plant in Assam should enable indigo to be produced at a price which could easily compete under natural conditions with synthetic.

The Débacle

I have dealt in this paper on very general issues only, and have neglected the many points of special interest to the scientific worker. These questions are fully dealt with in other papers, and a general review was given by Professor Armstrong at the Royal Society of Arts in 1922.

Up to a point everything appeared full of rosy promise, but in 1920 and 1921 the storm clouds which had been looming over India burst with all the violence of the typhoon. It is interesting that this storm had its origin in Bihar, the home of the indigo planter. In 1916 Mr. Gandhi first began operating in Bihar. When he first appeared on the scene, Mr. Morshead, the Commissioner of Tirhoot, realising the danger, issued an order excluding him from the province. Mr. Gandhi appealed to the Lieutenant-Governor, who revoked the Commissioner's decision. Mr. Gandhi was allowed to tour through the indigo districts of Bihar, where he—and more particularly his unscrupulous satellites—stirred up racial hatred and unrest. The Champaran inquiry followed which gave to Mr. Gandhi great prestige among his fellow Indians. Then came the massacre of Europeans in the Punjab, the Jallianwallahbagh incident, the cashiering of General Dyer (who, in the opinion of most Europeans, saved India from wholesale insurrection and massacre), and the introduction of the so-called "Reforms." We then saw all the disastrous effects of "putting new wine into old bottles"—the non-co-operation movement and its consequences.

The Government adopted the unprofitable and undignified course of attempting to placate the implacables. During 1920 and 1921 Bihar and Assam were in a very troubled state. In Bihar it became very difficult to obtain supplies of indigo plant and to work the factories; at many factories during the indigo season daily strikes occurred. Plant could not be grown or carted. Several factories were burned down by incendiaries and everything was in a state of uncertainty—even terror. Disaffection was stirred up in Assam also, and thousands of ignorant coolies were induced to desert the tea estates and return to their distant homes—often to perish miserably from starvation and disease on the way. The loss of the Russian market and the over-production of tea following the coarse-plucking introduced during the war led to a great slump in price, and the tea-planters for a year or two were selling their tea at a heavy loss.

The net result of all this was that in 1922—the year my agreement terminated—the Government of India was faced with a deficit which exceeded that of the previous year—which itself had constituted a record in the financial history of British India. Retrenchment became necessary; and not only was the indigo research abandoned but grants to the Indian Tea Association, to the Institute for Tropical Diseases, and other organisations were cut.

Before my agreement came to an end I had strongly recommended that the work be continued, as much still remained to be done; but in spite of this the Standing Finance Committee* stated that "it was the opinion of the Committee that sufficiently satisfactory results had been obtained by research in the past, and it was felt that the financial situation would not justify further retention of the officer." Strangest of all, the Hon. Member for Agriculture, in the Legislative Assembly,† after expressing thanks to me, announced: "We gave him notice the moment we found that his services were no longer required, and he himself informed the Government of India that he thought there was no necessity for any further research in that particular line. Therefore the House will note that officers are not anxious to continue a day longer than they think it necessary for their particular purposes, especially when they are engaged for special periods. (Hear, hear.)"

The statement here made that "I thought there was no necessity for any further research" is completely false. In my final report to the Government

* Report in the *Statesman*, February 1, 1922.

† Reports of the Debate of the Legislative Assembly held March 17, 1922.

of India I had strongly recommended continuance of the work in the following concluding words: "Much, however, still remains to be done. I would therefore recommend the continuance of the scientific work on indigo for a period of at least another five years. I feel sure that such extension will give an ample return to the country for the outlay incurred. Much of the spade work has been done, the benefit of which will be lost unless the work be carried through to completion."

How these words can be interpreted in the sense given above can be understood only by those acquainted with the subtleties of the Eastern mind.

When the news of the proposed abandonment of the indigo work was cabled home a vigorous attempt was made—without success—to move the Indian Government to reconsider its decision. On March 24 Prof. H. E. Armstrong put forward a powerful plea in a paper read at the Society of Arts, at which Sir Thomas Holland, who presided, stated that he "believed there were even good financial reasons for continuing the research work, at any rate for some years to come. To stop the work at its present stage, when the foundation facts had been established and results of direct commercial value were beginning to be available, would mean the waste of money already well spent. . . . The expenditure involved seemed to him almost negligible compared with that required for, say, a new University for the small city of Delhi, for which the Government had just placed a bill before the Central Legislature.

"On the facts it appeared that there had been a misunderstanding of a kind that proper representation should remove, and it would be for the benefit of India if the discussion of the meeting that evening helped the Government to reopen the question afresh."

Prof. H. E. Armstrong, in an eloquent appeal, after summarising all the facts, stated as his opinion: "Now I am prepared to affirm with far greater emphasis my belief in a secure future for indigo. My object has been to make clear the immensity and importance of the problems before us in agriculture, especially in connexion with leguminous crops. In view of their magnitude, it is the most serious reflection possible upon our intelligence that an industry, peculiar to the East, and particularly to India, undoubtedly in principle the root industry of its agriculture, of a lineage than which none is more ancient, should have no proper recognition and support. Agriculture is the chief industry of the country, yet it is to be deprived of scientific aid when it is in sorest need of help. . . . Opportunities lost are not regained. To interrupt the investigation at the present stage is an act nothing short of madness."

Nothing that could be done, however, had any effect in leading to a change of view on the part of the Government of India. The indigo work was abandoned, and the industry cut adrift. In concluding this brief account—one chapter only of the big story of indigo—I cannot do better than quote the words with which Prof. Armstrong opened his address at the Royal Society of Arts in 1922:—

"When the task was undertaken I had in mind the composition of a triumphal march, not of a dirge. Now I am overwhelmed by it, and have difficulty in joining a just measure of joy with my grief. The pen of a Gibbon alone could write the oration proper to the funeral at which we are met—for such it is. The work is to be discontinued, though the inquiry has been most fruitful from the beginning and is of the greatest public consequence.

"I would that the disease to which the patient succumbs could be diagnosed as the mere impecuniosity of the times; I fear it is far more grave and deep-seated—nothing short of general apathy and inability to appreciate the issues at stake, the need and value of acumen and understanding in agriculture. Yet agriculture, of all Indian industries, is beyond compare the most important; that in which considered, constant attention is most required. Indigo does not concern a few British planters alone; the problems underlying the successful cultivation of the plant are those of agriculture generally."

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL

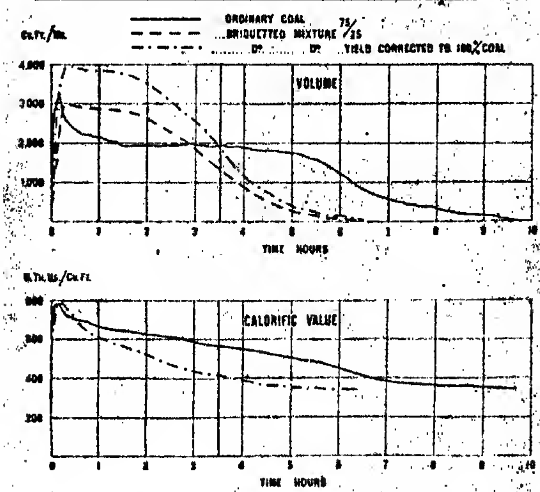
In the last of the series of Cantor Lectures delivered at the Royal Society of Arts on March 10 Mr. E. V. Evans described his ideas of what may take place when ordinary coal is undergoing carbonisation. It is conceived that the outer crust of the coal charge is rapidly transformed into coke even while some of the pieces of coal in the centre of the charge retain their identity. The slow transmission of heat into the centre of the charge is due to the cellular nature of the carbonised mass which results from the fusion of the resinous constituents of the coal. The way in which the plastic zone, which is indicative of this fusion, may gradually converge upon the centre of the charge, was depicted by means of a series of lantern slides. The formation of the plastic layer may be avoided, or at least very materially reduced, by admixing an inert absorbent material such as coke with the coal, and it was demonstrated experimentally that such a procedure enables a large increase in the rate of gas evolution from coal undergoing carbonisation to be obtained. The curves reproduced show the volume and calorific value of the gas obtained in the carbonisation of ordinary coal and of the same coal mixed with coke and briquetted without a binder. The carbonising process is accelerated to such an extent that the whole of the gas is expelled from the briquettes in 6½ hours as compared with 9½ hours for untreated coal. Thus even after allowing for the inert matter introduced into the retort there is an increase in the throughput of coal.

The laboratory investigations described in the previous lecture indicated that the yield of volatile products should be enhanced by such a process which involved more rapid carbonisation, and results of tests upon some 30 tons of briquettes were given to show that this was realised. Whilst an ordinary Durham coal gave 74·7 therms of gas and 10·1 therms of tar per ton, the same coal after being

briquetted with coke gave from 68·2 to 71·1 therms of gas and from 31·0 to 27·5 therms of tar per ton of coal.

After demonstrating the different nature of the solid residue resulting from the carbonisation of briquettes and that the formation of a plastic layer was in fact avoided, the lecturer put forward a hypothesis to explain why the enhanced yields of

VOLUME & CALORIFIC VALUE CURVES OBTAINED IN THE CARBONISATION OF ORDINARY COAL & BRIQUETTED COAL COKE MIXTURE 75/25



tar were obtained. The larger cells of normal coke require a considerable amount of binding material which is not required by the small-celled coke resulting from the carbonisation of briquettes. It is conceived that the pa ent substance from which the binding material originates is distilled away under the influence of more rapid heating and is the source of the higher yield of volatile products. Herein may lie the explanation of why many laboratory tests, such, for example, as the determination of volatile matter in a platinum crucible, fail to indicate the suitability of coals for carbonisation.

Briquette carbonisation makes possible the blending of coal prior to its being charged into the retorts, and the gas industry may in future put on the market a solid as well as a gaseous fuel of constant quality. Furthermore, there is the advantage that if a charge of briquettes is withdrawn from the retort after 3½ hours of normal high-temperature carbonisation there remains 5·6 per cent. of volatile matter in the coke and this is distributed uniformly throughout the mass. There is no central core of friable material such as results from the partial carbonisation of ordinary coal. The business of the gas industry may thus expand in the direction of providing a smokeless fuel suitable for general domestic use. In this connexion the removal of ash from the coal becomes a question of some importance, and the several types of process for [illegible]

FORTHCOMING EVENTS

Mar. 22. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Properties of Gases in Vacua," by Prof. Sir E. Rutherford. *Also on March 29, at 3 p.m.*

Mar. 24. Institution of Mechanical Engineers, Storey's Gate, S.W. 1, at 7 p.m. Informal discussion on "Failure in Metals."

Mar. 24. Royal Society of Arts, (Cobb Lecture), John Street, Adelphi, W.C. 2, at 8 p.m. "Certain Fundamental Problems in Photography" (Lecture I.), by Dr. T. Slater Price.

Mar. 26. Society of Chemical Industry, *Nottingham Section.* Annual Meeting, followed by an ordinary meeting, at which papers will be read by the late J. M. Wilkie and collaborators.

Mar. 26. Royal Society of Arts, at 8 p.m. "The Fishing Industry and its By-Products," by N. Green.

Mar. 26. Royal Microscopical Society, 20, Hanover Square, London, W. 1. Dr. Stephen Miall will preside. (1) "Methods of Mass-Production in Sectioning Flax Stems," by G. O. Searle. (2) "Microscopical Metallurgy," by Dr. H. Wrighton, D.Met., (3) Lecture Demonstration on "Technical Microscopy." No. 4, by J. E. Barnard.

Mar. 27. The Chemical Society. Annual General Meeting, Burlington House, Piccadilly, W. 1, at 4 p.m. Address by Prof. W. P. Wynne, D.Sc., F.R.S. An Informal Dinner will be held at the Hotel Cecil, Strand, W.C. 2, the same evening, at 7 for 7.30 p.m.

Mar. 28. Society of Chemical Industry, *Chemical Engineering Group*, the Lecture Theatre of the Institution of Civil Engineers, Great George Street, S.W. 1, at 6 p.m. "Kinetic Elutriation," by L. Andrews.

Mar. 28. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Insulin," by Dr. H. Maclean.

Mar. 28. Society of Chemical Industry, *South Wales Section*, the Technical College, Mount Pleasant, Swansea, at 7.15 p.m. Annual Meeting, addressed by Capt. H. Vivian. "Notes on the History of Copper Smelting in Swansea."

Mar. 28. Society of Chemical Industry (*Newcastle Section*), Newcastle Chemical Industry Club, and Institute of Chemistry (*Newcastle and N.E Coast Section*). Joint Dinner to be held at Tilley's, Blackett Street, Newcastle, at 7.30 p.m. Chair to be taken by Prof. Henry Louis.

Apr. 7. London Section, at Royal Institution, 21, Albemarle Street, W. 1, at 8. Prof. H. E. Armstrong, F.R.S., will deliver an address on "Sir James Dewar as an Experimentalist," with demonstrations.

Note.—Owing to an error in setting up the type of the meeting of the Birmingham Section of the Society of Chemical Industry, held on March 18, the paper read at that meeting on "The Relation of the Theobromine Content of Cacao to its Fermentation," was included under the notice of the Birmingham Section of the Institute of Metals.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

PRELIMINARY NOTICE

The Annual Meetings of the Society will be held in Liverpool from Wednesday, July 9, 1924, until Saturday, the 12th inclusive.

His Majesty the King has been graciously pleased to grant his Patronage to the Meeting.

The Presidential Address will be delivered by Dr. E. F. Armstrong, F.R.S., and the Messel Lecture will be given by the Rt. Hon. Viscount Leverhulme.

A limited number of technical papers will be read, and there will be visits to at least two large works in the neighbourhood.

A very interesting programme is being arranged by the Local Committee under the Chairmanship of Mr. Edwin Thompson, who was largely responsible for the great success of the British Association meeting in September last.

Whilst the business and technical side will be adequately represented in the programme, arrangements will be made to make the meeting an attractive social event.

It is hoped that many of the Society's overseas members who are coming to this country to visit the British Empire Exhibition will arrange their visit so that it may be possible for them to be present at the Society's Annual gathering.

Further particulars will be intimated shortly.

MEETING OF COUNCIL

The monthly meeting of Council was held on March 14, 1924, the President, Dr. E. F. Armstrong, F.R.S., in the chair.

The President brought forward consideration of the proposed arrangement between the British Dyestuffs Corporation and the Interessen Gemeinschaft, and after some discussion it was agreed to leave it to the Federal Council for Pure and Applied Chemistry to take any action in the matter.

A second grant of £250 was made towards the cost of the Scientific Exhibit at the British Empire Exhibition, 1924.

A preliminary programme of the Annual General Meeting to be held in Liverpool on July 9 to 12 next, was submitted.

It was reported that Mr. F. E. Dickie has resigned the Honorary Secretaryship of the Shawinigan Falls Section of the Society, but the name of his successor has not yet been received.

Mr. Charles E. Munroe, Chairman of the National Research Council, Washington, D.C., and Mr. W. Alan Gibbings, of Cheltenham, will attend the Annual Meeting of the American Chemical Society, to be held in Washington in April, as delegates from the Society of Chemical Industry.

Mr. W. F. Reid was nominated as delegate from the Society to the Kelvin Centenary Celebrations, which will be held in London on July 10 and 11; and Mr. E. V. Evans was nominated the Society's representative at the Jubilee Celebrations of the Physical Society, which will take place in London on March 2[illegible] to 22. It was decided to send an Address of Congratulation to the Physical Society.

Reports of various Committees of the Council were submitted, and 27 new members were elected: Home, 20; Overseas, 7.

The next meeting will be held on Friday, April 1[illegible], 1924, at 2.30 p.m.

OFFICIAL NOTICE

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports, covering the year 1923, is now ready. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members. Vol. I is out of print, but copies of Vols. II, III, IV, V, VI, and VII may be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d., and 7s. 6d., and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d., and 12s. 6d. respectively.

If Vols. II, III, IV, V, VI, and VII are ordered at the same time as Vol. VIII, the set may be obtained by members for £2 2s. 6d., and by non-members for £3 15s.

The appropriate remittance must accompany every order. The books are sent to purchasers post free.

LIST OF MEMBERS ELECTED, March 14, 1924

Beeson, John B., 121, City Road, Chester Green, Derby. Chemical Plant Draughtsman.

Bennett, Miss Hilda, 423, Addison House, Grove End Road, London, N.W. 8. Analytical Chemist.

Benton, William A., 91, Allen Road, Wolverhampton. Technical Adviser.

Brierley, John P., Heath Cottage, Daryl Road, Heswall, Cheshire. Analytical Chemist.

Butterfield, Henry H., 95, King's Avenue, Watford, Herts. Analytical and Manufacturing Chemist.

Carson, Samuel D., 184, Main Road, Handsworth, Sheffield. Chemist.

Dutton, Charles F., Powell Duffryn Buildings, Cardiff. Salesman.

Flett, Thomas, Anchor Cottage, Kirkwall, Orkney. Chemist.

Gabriel, Charles L., Commercial Solvents Corpn., Terre Haute, Ind., U.S.A. Chemical Engineer.

Galley, John V., c/o Imperial Trading Co., 275, Craig Street W., Montreal, Canada. Chemical Importer.

Gracie, David S., School of Agriculture, Reaseheath, Nantwich. Lecturer.

Jones, Walter B., The United Steel Cos., Ltd., Rother Vale Collieries Branch, Treeton, nr. Rotherham. Director.

Kieser, Miss Margaret E., 42, Ravenswood Road, Redland, Bristol. Technical Chemist.

McConnachie, William, Coltness Iron Works, Newmains, Lanarkshire. Chemist.

Morgan, Harold M., 48, Spelman Street, London, E. 1. Pharmaceutical Chemist.

Murphy, Harold N., 57, Palmerston Road, Sheen, London, S.W. 14. Manufacturing Chemist.

(To be continued.)

SOUTH WALES SECTION

At the meeting at Swansea on February 15 a joint paper on "The Increasing Use of Physical Methods for Purposes of Control," by Messrs. L. Taverner and H. J. Williams, was read by the latter.

Until comparatively recently analytical methods of control only had been used in the production of finished metals for various purposes. Such methods enabled the production of metal of chemical composition, fitting it for the desired use, and the composition thus obtained would persist. Subsequent alterations would be of physical, not chemical, nature, necessitating physical methods of control during manufacture. Earlier attempts at this—bend, drift and welding tests for wrought iron and steel—with the more modern mechanical tests called for by engineers—were applied to finished metals to ensure that these had the desired properties, and were in no sense "control methods." Other methods had to be sought, originally to explain failures, the microscope being the first aid in this direction. Accurate temperature measurement was necessary for the work carried out by Roberts-Austen for the Institution of Mechanical Engineers, and this led finally to the adoption of Le Chatelier's thermocouple, which, combined with a recording device, rendered accurate temperature measurements, and records, possible. Previously, other forms of pyrometer—Wedgwood's, Siemens, Carnelly's—had been used; almost every physical property had been utilised for high-temperature measurement.

Workers turned first to iron and steel, and Hadfield's observation that 1·16 per cent. carbon steel could not be hardened below Barrett's "recalescence point," but, hardened from 15° C. higher, was glass hard—a difference no worker, however skilled, could detect without instrumental aid—led to a demand for pyrometers, which had persisted, until now these instruments were almost universally used. Instances were quoted of the detection of causes of failure by means of the microscope, which also indicated the remedy, for the application of which pyrometers were necessary. Examples of the application of "macrography" were also dealt with, and the various methods of determining hardness discussed, together with the modern methods of fatigue test, and the application of X rays.

At the conclusion a number of lantern-slides was shown, exhibiting, among other things, the extreme ease with which the change in properties of steel with increasing temperature can be followed by the aid of the microscope, and also some typical cases of failures in steel, the cause of which was, at once evident on microscopical examination.

At the meeting at University College, Swansea, on March 14, Mr. J. R. Green read a paper on "Suggestions for Spectrum Analysis in Works Laboratories." Prof. J. E. Coates, O.B.E., D.Sc., who was in the chair, explained that owing to the inability of another member to give his expected paper Mr. Green had made up the deficiency at short notice.

The lecturer gave a short summary of the work of W. N. Hartley, and of Pollok and Leonard, on spark spectra of metallic solutions. They found that spectra of dilute solutions were always much simpler (containing fewer lines) than those of concentrated ones, but the fact that they used solutions and worked with spark spectra limited the usefulness of their results. A. de Gramont had greatly extended this work, and had found that as the relative proportion of an element (usually metallic) in a substance decreased, there were always certain definite lines which were the last to disappear. These he had called the "raies ultimes," and they lay usually in the ultra-violet, so that they could not be photographed by attaching a camera to the usual spectroscope with glass lenses and prism.

There were usually, however, a number of sensitive lines in the visible spectrum of a metal, and the copper arc was used to show those of the copper spectrum; this fact rendered it possible to use a direct-vision spectroscope, in conjunction with a camera, as a spectrograph. It was preferable to use a replica diffraction grating to obtain the spectrum, as it gave much higher dispersion, and the wave-length scale was more even. The construction of a simple spectrograph, using a grating replica, was shortly described, and a number of lantern slides of spectrograms taken on it were projected to show the sensitive lines of iron, tin, lead, zinc, copper, nickel, and sodium.

Very fair quantitative results could be obtained by comparing the intensities of lines with the intensities of the same lines in spectrograms, taken under the same conditions, of similar substances (*e.g.*, alloys) of known composition. The rapid estimation of traces of impurities in this manner was often of the greatest value in a works laboratory. Hill and Luckey had shown that lead could be estimated in a couple of minutes or so in copper, by measuring the time for the violet line (4058 Å.U.) to vanish or to be reduced to a given intensity, using a button of copper, 0·4 g. in weight, in the positive crater of a carbon arc. The lecture concluded with a demonstration of the taking of a spectrogram of some tin of unknown purity, using the grating spectrograph described, and pure tin as comparison substance. The sample was found to contain iron, estimated at 0·25 per cent.

There was a short discussion, and the meeting terminated with a vote of thanks to Mr. Green.

NOTTINGHAM SECTION

At a meeting on March 12, Mr. G. J. Ward, of the Stanton Iron Works, read a paper entitled "The Effect of Centrifugal Action on Concrete."

If a concrete mixture be put into a cylindrical mould and the mould be rapidly rotated about its axis, the concrete will be forced towards the periphery of the mould and will form a lining to it. If the spinning be continued long enough the concrete will retain its form after the mould is brought to rest. Hence the use of this process in the manufacture of pipes. A speed of about two feet per second is maintained during filling of the mould, but an increased speed causes the larger and heavier particles to move outwards. This movement obeys the same laws as those governing the settling of particles in

water. The limiting velocity of large and small particles settling together is given by $K\sqrt{D(d-1)}$ where D is the diameter of the particle in inches. d its specific gravity, and K a constant of value 0·16. At the end of three minutes' spinning, the aggregate was well packed and the inner lining was solidified. Excess water is swept out from the bottom, and a polishing bar passed through while the mould is revolving again for another minute. The pipe is then left for 10 hours in an atmosphere of steam at 90° F. and is then removed to the stockyard for further maturing. The author considers that the spinning set is almost entirely a physical and not a chemical effect. Methods were then given for the determination of the right proportions of aggregate, sand and cement, and also for measuring the strength of the resultant concrete. A number of slides were shown illustrating both the theoretical and practical sides of the process.

During the discussion Mr. Droop Richmond asked if the sole object of the aggregate (granite) was for hardening the outside surface, and also if the formula $\sqrt[3]{D(d-1)}$ would not be more approximate. Mr. Burford enquired as to the composition of the framework for the original mould. With respect to the chemical change involved in the setting of the concrete, would not heat be generated giving rise to expansion? Was it necessary to have an approximate chemical formula for the concrete at the finish? Mr. Gray asked if there was any relationship between the bursting strengths of spun and ordinary concrete. Mr. Pentecost enquired as to the method of introduction of the concrete into the mould; was it weighed or measured?

In reply Mr. Ward stated that the outside surface of the pipe was hard even without granite; the chief use of the aggregate, however, was to fill the interstices, and thus economise in the amount of cement necessary. With reference to the formula $K=\sqrt{D(d-1)}$, although this was empirical, it was approximately correct, and was found to give good results when used in connexion with coal washing. There would possibly be a slight increase in the temperature on setting of the concrete, but any expansion caused thereby would hardly be noticeable owing to the same amount of expansion in the mould, as steel and concrete possessed about the same coefficient of expansion. In resistance to external stresses, spun concrete was certainly stronger than ordinary concrete. The concrete was shovelled into the revolving mould, and the amount was gauged fairly accurately by noticing the thickness. A chemical formula was not involved in the setting of the concrete.

GLASGOW SECTION

The meeting held in the Institute of Engineers and Shipbuilders, on March 11, was presided over by Mr. W. E. Moodie, Chairman of the Section, and two papers were read.

The first paper was on "Modifications of Laboratory Apparatus," by Prof. T. S. Patterson, D.Sc., Ph.D., in which a descriptive account was given of (1) an extractor; (2) a receiver for distillation under reduced pressure for very small quantities of distillate; (3) a modified internal condenser which allowed of substances being introduced into the flask without removal; (4) an absorber; (5) an improved type of sodium press with increased number of holes; and (6) a convenient form of reaction chamber and pressure-equalising dropping funnel. The speaker said that these various forms had been evolved from time to time to replace or modify forms at that time in use which had been found in many ways to be lacking: he had thought that as they had proved so useful, many members might possibly find them of use also.

Prof. Patterson was warmly thanked, on the motion of the Chairman, for his paper and for the trouble of exhibiting the forms described.

Mr. T. C. Mitchell then read a summary of a paper on "The Electrical Conductivity of Solutions of Double-Salts," which had gained the award for him of the Student Associate Prize of the Glasgow Section; he showed how this was a logical continuation in its way of the work of Caven and Ferguson; they had examined in solid form the resistance to dissociation of various double-salts to heat: he himself had examined their resistance to dissociation in fluid medium to dilution. Pure salts were used and the following types were examined:—

I. The electrical conductivity of solutions of $CuSO_4$, $CoSO_4$, $ZnSO_4$, $NiSO_4$, K_2SO_4 and $(NH_4)_2SO_4$.

II. The conductivity of equimolar solutions of $CuSO_4$ and $ZnSO_4$ mixed. This was found to approximate within experimental error to the mean of those observed in the simple systems. This was taken as the type of non-double-salt-forming system.

III. The conductivity of solutions of salts RSO_4, $M_2SO_4.xH_2O$, where R=Cu, Co, Zn, or Ni, and M=K or (NH_4).

In conclusion, Mr. Mitchell said that it was very difficult to generalise from the results obtained, but, if anything could be said, he might state that in every case examined the observed conductivity of the double salt was less than that calculated by taking the mean of those of the equimolar solutions, and this difference he had expressed in percentages on the basis of the mean calculated result: he called this the percentage difference. This indicated that the salts had not been completely dissociated at the dilutions examined. With the Cu and Co salts, this percentage difference, at any given dilution, was greater in the case of complexes with K than with NH_4, but this was reversed in the case of Ni and Zn salts. Further investigation was therefore desirable. The Cu salts showed a unique lack of dissociation with dilution, adding one more interesting example of the curious behaviour of this radicle in this series.

Mr. Mitchell was complimented on his paper and cordially thanked for his summary of it.

A discussion was then opened by Mr. Gilbert Gunn on "The Use of Pulverised Fuel for Boiler Heating." A short historical account was given by the speaker, who then described the modern construction of suitable furnaces. He described difficulties he had

encountered, and hoped that the discussion would clear up some of these difficulties. An exceedingly vigorous discussion followed, in which several members took part. Mr. Gunn was thanked for his contribution to the discussion.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on March 13, Sir William Pearce presiding in the absence of the Chairman through illness. The Council considered a request from the Chemical Society for financial support towards the upkeep of the Library, and after receiving a report on the working during the past year agreed to give a donation of £250. The Society must not take this as a precedent, and the donation is made on the understanding that members of the Association are at liberty to make use of the Library through their accredited representatives.

The General Manager presented a report dealing with the arrangements in connexion with the Chemical Section of the British Empire Exhibition and with regard to the scientific exhibit said that already £4206 10s. had been subscribed towards the cost thereof. A further £1800 is still required. The arrangements for the publication of the technical volume entitled "Chemistry in the XXth Century" are well in hand.

A letter was received from the New Zealand and South Seas Exhibition Company, Ltd., giving notice that an Exhibition of the World's Arts, Products and Manufactures will be held in the City of Dunedin, New Zealand, during 1925-1926, the opening date being approximately November 1, 1925. The Council decided that the Association as such could not participate in the Exhibition.

Various routine matters were also dealt with.

SOCIETY OF PUBLIC ANALYSTS

An ordinary meeting was held in the Chemical Society's Rooms on March 5, Mr. G. Rudd Thompson in the chair, and five papers were read.

I—"The Composition of Beef and Malt Wine" was discussed by G. D. Elsdon, B.Sc., who described a recent case of adulteration of beef and malt wine. He gave the composition of various extracts of beef and malt, including those taken from previously published works, and those obtained under ordinary commercial conditions, and examined by himself. A number of analyses of wine likely to be used in the preparation of beef and malt wines were also given, and a standard was suggested which all commercial samples of such tonic wines should reach. Finally, fairly complete analyses of a number of commercial tonic wines were detailed.

II—A paper on the "Effect of Fatty Diet on the Composition of Butter Fat" was presented by Prof. J. C. Drummond, D.Sc., and H. J. Channon, B.A., B.Sc. Cows were given, as a supplement to a fixed basal ration of a very low fat content, coconut, arachis and cod-liver oils in amounts varying from 2 to 8 oz. per day for periods up to 35 days. At intervals samples of butter fat from the milk of individual cows, were examined for Reichert-Wollney, saponification and iodine values, refractive index and vitamin A content. Curves showing the rise and fall in these values show marked similarity in the different cows, and would appear to indicate definite passage of the oils to the butter. The percentage of total fat showed a distinct fall during the cod-liver oil feeding, but whether this is due to a specific effect of the oil or to the advancement of the period of lactation, is uncertain. The vitamin A value rose markedly during this period. Attempts to make a quantitative study of the effect of the oil feeding on the composition of the butter fat, by fractional distillation of the methyl esters of the fatty acids, failed. The technical difficulties of fractionating esters of a series of acids so closely related, appears too great for the method to be of any use in quantitative work. The majority of recorded analyses of butter fat, particularly those in which the percentage of each fatty acid is given to one or more places of decimals, are regarded as of doubtful value.

III—Mr. G. D. Elsdon, B.Sc., read a paper entitled, "What is Bondon Cheese?", in which he reviewed the evidence with regard to the composition of Bondon cheese. The opinion was stated that a Bondon cheese should be a whole milk cheese, and should therefore contain at least 20 per cent. of fat. Objection was taken to the pleading of "Trade Custom" in prosecutions under the Sale of Food and Drugs Act, merely because possible adulteration has been carried on unchecked for a number of years.

IV—"Cream Cheese" was the title of a paper by T. R. Hodgson, M.A., who objected to the standard of 20 per cent. of fat in cream cheese proposed to be set up in the recent legal proceedings instituted by the Holborn Borough Council because it did not take into account the composition of the original milk from which the cream cheese was made; the suggestion was made that in any similar prosecution, the vendor should be charged with selling cream cheese made from a milk partially deprived of its fat; an appeal from such an information would have to be taken to the High Court of Justice instead of to the Quarter Sessions, and the decision of the High Court would, of course, be binding on the whole country, whereas the decision of the London Quarter Sessions is binding on London only.

V—"Some Facts on the Composition and Decomposition of Eggs" were detailed by R. J. Thomson, F.I.C., and James Sorley, F.I.C. Contrary to Jean's statement, the fat could be completely extracted from dried egg yolk by any of the three solvents—petroleum spirit, ether or chloroform. A small proportion of any boric acid present was simultaneously extracted by petroleum spirit or ether. Repeated extraction with ether, in a separator, of yolk diluted with water removed all the fat, but petroleum spirit extracted only a small fraction of it. The yolk of a recently lai hen's egg contained 0·59 per cent. of free fatty aci (1·72 per cent. of the fat) and 4·28 per cent. of ur saponifiable matter. It was shown that extractio with petroleum spirit removed only a small percentag

of the unsaponifiable matter from the yolk. The constants of the fat from the yolks of hen's and duck's eggs, and from preserved Chinese hen's egg yolks were given, the last being characterised by high acid values. Decomposition of egg yolk was accompanied by a gradual rise in the acid value of the fat.

BIOCHEMICAL SOCIETY

The Annual General Meeting was held at the Lister Institute on March 10, and the following papers were read :—

"Studies in Phosphorus Metabolism. I. The Effect of Insulin on the Phosphoric Esters in Blood and Muscle," by H. D. Kay and R. Robison. During an investigation of the "acid-soluble" phosphorus in blood, muscle and other tissues, it was found that the amount of readily hydrolysable organically bound phosphate contained in muscle was markedly increased (15 per cent. to 25 per cent. increase on the normal amount) when insulin had been given to a rabbit, if the animal was killed at, or just before, the onset of convulsions. Two methods have been employed. The first entails the use of a preparation of an enzyme present in bone which readily hydrolyses phosphoric esters; the second consists in a modification of Embden's "lactacidogen" determination. Results by both methods agree. Accepting the statement made some years ago by Embden and his collaborators that the main phosphoric ester present in muscle is a hexose phosphoric ester, the discovery of a definite increase in this substance after insulin affords a probable explanation of the fate of the sugar which disappears from the blood, and which, it is known, is neither transformed into glycogen nor fat. The increase in organically bound phosphorus ("lactacidogen") actually found accounts for about three times the amount of sugar which disappears from the blood. This does not take into account any mobilisation of sugar from glycogen or other reserves. These results agree with those just published in abstract by Wagner and Andova who, using a slightly different method, find about the same increase in "lactacidogen" after insulin.

"A Method for Investigating Calcium and Phosphorus Metabolism in Rats" was described by A. Boas. In determining retention of calcium and phosphorus the metabolism cages of Hopkins and Ackroyd were used. The calcium and phosphorus were estimated in (1) the total food offered, (2) the uneaten food and urine and faeces, the difference being the amount retained. Estimations of calcium were made by McCrudden's method, the phosphorus by Neumann's method, after calcining the material in a porcelain crucible in a small furnace specially designed for the purpose by Prof. C. J. Martin.

M. A. Boas and H. Chick read a paper on the "Influence of Diet and Management of the Cow upon the Calcium and Phosphorus Retention of Rats fed upon the Milk." The samples of milk tested by Luce were also investigated for value in inducing retention of calcium and phosphorus in young growing rats by metabolic experiments lasting four-six weeks. The results were in accordance with those obtained by Luce. The milk was fed in daily doses of 15 c.c. as supplement to a diet lacking in fat-soluble vitamins. Rats receiving milk taken from the cow when in the dark stall on dry fodder or on fresh green fodder showed retention of calcium markedly below normal, the phosphorus retention being less affected. Rats receiving the same dose of milk from the same cow when pasture fed in summer showed normal retention of calcium and phosphorus.

Mr. E. M. Luce discussed the "Variations in Growth-promoting and Anti-rachitic Value of Milk from the same Cow kept under varying Conditions of Light and Diet." A cow was maintained for a period of about 18 months under strictly controlled conditions of diet and light, following upon several months of pasture-feeding.

(1.) July-October, 1922. Dry fodder, poor in fat-soluble vitamin (maize and gluten meal, crushed oats and barley, mangolds, chaff, and barley-straw), the cow remaining out-of-doors on a ploughed paddock.

(2.) November, 1922-May, 1923. Cow placed in a completely dark stall, diet being unaltered.

(3.) May, 1923-July, 1923. Diet of fresh meadow grass and clover, the cow remaining in a dark stall.

(4.) August, 1923-October, 1923. Pasture feeding.

The milk given at the end of Periods 1-4 respectively was tested for :—(1) Growth-promoting value (using rats); (2) power of inducing calcium deposition; (3) anti-rachitic value, by determining the daily dose required to prevent rickets in young rats receiving McCollum's rickets-producing diet, deficient in fat-soluble vitamin and in phosphorus.

The milk from Period 4 was found to possess all three properties in a high degree, a daily dose of 3-5 c.c. restoring growth and also preventing rickets; that from Period 3 was intermediate, whilst milk taken from the end of Period 2 was most deficient in all respects, doses up to 20 c.c. proving less efficient than pasture-fed milk. The results showed conclusively that summer milk from a pasture-fed cow possesses specific value for prevention of rickets in a high degree, also that wide variations in the growth-promoting and anti-rachitic power of milk from the same cow can be induced by alterations in diet and management of the animal.

PARLIAMENTARY NEWS

Nitrogen Fixation

Mr. S. Walsh, replying to Mr. Hayday and Major Moulton, said he was aware that the French Government had recently concluded an agreement with the Badische Anilin und Soda Fabrik for the exploitation of methods of manufacturing synthetic ammonia. His attention had also been called to the acquisition by the French Government of the patents and technical information necessary for the production of nitrates by the Haber-Bosch process with a view to the production of nitrates on a large scale in France. Similar steps had been taken by the British Government in conjunction with a British firm.—(May 11.)

CORRESPONDENCE

THE ENGLISH LANGUAGE

SIR,—The importance of the correct and effective use of our own language is being more and more recognised by most professional men in this country, especially by chemists and engineers. Hence I may perhaps be allowed to make a few comments on this subject, supplementary to the excellent editorial paragraph that appeared on p. 1225 in the December issue of this Journal last year. It seems to me somewhat of an inversion of the natural order of things that Englishmen should consult the book of an American author in order to learn how to write our common language correctly. The important task of producing a work of this kind was taken in hand many years ago by the Rev. Dr. E. A. Abbott, the well-known headmaster for several years of the City of London School, whose little two-shilling book, *How to Write Clearly* (Seeley) reduces the subject to short rules, followed by excellent examples and exercises. (Old City of London boys will be pleased to note that Dr. Abbott is still alive.) In the preface to the book the author observes: "Speeches in Parliament, newspaper narratives and articles, and, above all, resolutions at public meetings, furnish abundant instances of obscurity arising from the monotonous neglect of some dozen rules." Whether this strong indictment still holds good, I must leave present-day Members of Parliament, etc. to answer for themselves. One of the rules is as follows: "Do not introduce literal statement immediately after metaphor."

The first example given of neglect of this rule is of special interest to chemists. It runs thus: "He was the father of Chemistry, and brother to the Earl of Cork."

The gentleman here referred to is doubtless the Hon. Robert Boyle, who was the fourteenth child and youngest son of the first (the "great") Earl of Cork, and is known to all of us as the discoverer of the fundamental law connecting the volume and pressure of a gas. He was also the founder of the "Boyle Lectures." The Hon. Robert Boyle was buried in the Church of St. Martin's-in-the-Fields, Trafalgar Square, but whether the above formed part of an epitaph I have not been able to discover.—I am, Sir, etc., A. E. JOHNSON

24 Parkdale,
Wolverhampton

THE EPILATION OF SKINS

SIR,—In reply to Dr. Ross's letter in your issue of March 7, I propose to leave the question as to what are "howlers" to your readers.

With regard to my remarks about tanning, Dr. Ross ought to know that when we speak of tanning, we mean all the processes from the raw skin onwards, and as is well known, the preparatory processes are the most important part of the work. To quote a saying of the late Lord Allerton, "good leather is made before ever the skins go into the tan liquor."

I have not said that epilate is incorrect, but the use of the word by Dr. Ross is pedantic. The word depilate is in common use, as is also the word depilatory. As to the *direction* in which the hair is pulled out, I say nothing.

The reasons why I stated that Dr. Ross's results are not true are:—

(1) Thrombin, or thrombase, is not a proteoclastic enzyme, but a coagulating enzyme. See Hammarsten, "Physiological Chemistry," p. 299 *et seq.* Also Effront, 'Biochemical Catalysts," p. 33 *et seq.* There is no evidence that thrombin "digests the rigid insoluble protein fibrin," as stated by Dr. Ross.

(2) "Saproprotease" or bacterial trypsin, or bacterial tryptase, whichever term you prefer, exists in the soaks, but is not found in the limes, except in very small quantities. The reason for this is now evident from Collet's work, which I quoted, in which it is shown that the bacteria from the soaks are killed by the lime, and that the organisms which are always found in old limes are merely surviving.

In answer to Dr. Ross's request for the methods used in examining the limes for tryptic enzymes, I used Fermi's method ("Alte und neue Methode zum Nachweis der proteolytischen Enzyme, Centr. Blatt f. r Bakt." Bd. XVI., p. 176). See also Wood and Law, "Some Notes on the Enzymes concerned in the Bating and Puering Process" (*J.S.C.I.*, 1912, p. 1105), in which details of the method are described. The limes were tested both in their original condition, and also after careful neutralisation. No tryptic enzymes were found.

Dr. Ross's description of blood as a "chemical" will be new to most of us. In the tannery in which I am occupied we get rid of all the blood as thoroughly as possible, and yet the skins unhair.

Dr. Ross refers me to his experiments. In his paper he twice states that salt is an inhibitor, and having replaced a guinea pig's blood by saline solution, and so prevented unhairing action, he concludes that thrombin is the unhairing agent, because no unhairing occurred when the blood was replaced by the saline solution. I confess I cannot follow the logic of this deduction.—I am, Sir, etc.,

Nottingham JOSEPH T. WOOD

March 15, 1924

THE PROJECTED ANGLO-GERMAN DYE AGREEMENT

SIR,—By inadvertence the name of Mr. E. Ford Morris, M.I.Chem.E., Chairman of Council, was omitted from the list of members of the recent deputation to the Board of Trade on the British Dyestuffs Corporation and Interessen Gemeinschaft agreement.

I shall be extremely obliged if you will be so good as to inform your readers of the fact.—Yours faithfully, A. STEWART MILLS,

Assistant Secretary, the British Association of Chemists

London,
March 8, 1924

QUALIFICATION OF CHEMISTS

SIR,—May I be allowed to draw attention to an aspect of this question which is apt to be lost sight of. It has been the practice of public analysts generally (all Fellows of the Institute of Chemistry) to take youths in to be trained as analytical chemists. Sometimes a fee may be charged and in other cases a small wage may be paid, but this point is immaterial. At least one well known firm of public analysts, to my knowledge, makes no attempt to teach these students or apprentices any theory. Nor is it suggested that a youth on entering such an apprenticeship should endeavour to take a degree. Consequently they acquire a certain amount of skill in performing analytical operations, but the knowledge of chemistry which they possess depends on their own independent study, which must necessarily be done in their spare time. Under such circumstances I admit it is possible to take a degree, but it is extremely difficult. At least it was not done very often 15 or 20 years ago. Many men, however, did become qualified, both by study and practice, to hold the title chemist, yet hold no academic qualification.

Now the point I wish to make is this. The Institute of Chemistry, through its members, has trained hundreds, probably thousands of men in the above system. Many of the men so trained have held good positions and have done useful work as "Works Chemists." Now the Institute wants to turn its back on those men and deny them the right to call themselves chemists, and, as a consequence, prevent them from holding positions as such. Also, it is becoming increasingly difficult to obtain a good post, or a post of any kind, unless the applicant holds some academic qualification, or is an A.I.C. Experience comes second to other qualifications in many cases. I agree that the movement in this direction is inevitable and is also right; but what of the large body of "Unqualified Chemists" who have no hope now of obtaining the necessary qualification and who are greatly handicapped thereby?

Mr. Claremont in your issue of March 7 says:—"The Institute of Chemistry has already done much to open its portals to all *bona fide* chemists." How? I was not aware that one could enter the Institute except by examination. Continuing, he says:—"In the near future it may be hoped that all chemists worthy of the name will take these qualifications." Again I ask how is the man or 35 or 40 going to take these qualifications? Is the Institute going to let him in by the back door, or has he to turn to and spend several years' hard work to pass the necessary examinations, a task well nigh impossible to many quite experienced chemists? I agree that it is desirable that chemistry should be a closed profession, but before it is made so provision should be made for those who entered the profession before a degree was considered necessary.—I am, Sir, yours faithfully, "AN UNQUALIFIED CHEMIST"

Sir A. Duckham, who has been visiting the United States in connexion with questions of low-temperature carbonisation, has now returned to England.

PERSONAL AND OTHER NOTES

Duke M. de Broglie, the eminent physicist, who has done such valuable work on X-rays, molecular physics, etc., has been elected a member of the Académie des Sciences in the Section of Free Academicians by 36 out of 66 votes. The other candidate was the well-known chemist, Prof. A. Desgrez, who received 29 votes.

Sir Max Muspratt, Bart., has been appointed by the Association of British Chemical Manufacturers as one of its representatives on the Federal Council.

Dr. James Kenner, Senior Lecturer in Chemistry at Sheffield University, has been appointed Professor of Organic Chemistry at the University of Sydney. During the war Dr. Kenner was in charge of the big gas station at Calais, being responsible for almost the whole of the phosgene gas used by the British Army in France. He has been at Sheffield University for 14 years, and has carried out many researches in organic chemistry.

Count L. M. H. de Chardonnet, who has died at the age of 84 years, was the first to develop a commercial process for the preparation of artificial silk, his patent being dated 1884. Count Chardonnet, who was a member of the Institut, also carried out interesting work on ultra-violet rays. An extended notice will be published later.

Chemical Society

The annual general meeting of the Chemical Society will be held at Burlington House on Thursday, March 27, at 4 p.m., when the President will deliver his address, and the Longstaff medal for 1924 will be presented to Prof. F. G. Donnan, F.R.S. The informal dinner will be held the same evening at the Hotel Cecil at 7 for 7.30.

FRANCE

Output of Iron Ore

The production of iron ore in 1923 was 23,225,564 metric tons, compared with 21,032,000 t. in 1922. Stocks at the mines at the end of December were 4,473,749 t.

Alcohol

The total output of alcohol during the first four months of the 1923-24 season was 1,114,756 hectolitres, of which 632,368 were reserved for the State, and the rest placed on the market. Imports were 90,997 hl., exports were 73,358 hl., and stocks on January 31 were 1,177,137 hl.

Industry in the Ruhr

At present 33 blast furnaces are alight in the Ruhr, compared with 45 before the Occupation. Those steel works which are in the vicinity of waterways and supplies of coal, are producing 50 per cent. of their normal output, the others producing from 35 to 30 per cent. Complaint is made of lack of orders. The average production of the coal mines not included under the French Regie, is 237,980 t. per day, compared with 369,445 t. in 1913.

REVIEW

SECOND YEAR BOOK OF THE INSTITUTION OF THE RUBBER INDUSTRY, 1923. *Pp. xxiv+448. London*: 10, *Charing Cross Road*, 1924. *Price 5s.*

The second number of the "Year Book of the Institution of the Rubber Industry" contains much interesting material and provides evidence of the growth in membership and utility of the Institution. Altogether 23 papers are printed in the Year Book, which opens with Mr. F. Kaye's paper on the use of rubber latex-making and includes scientific contributions from workers such as Messrs. H. P. Stevens, B. D. Porritt, W. A. Williams, D. F. Twiss, P. Schidrowitz, and others. There are also papers devoted to the commercial side of the industry, a feature which well illustrates the aim of the Institution: "To promote a better understanding and closer relationship between all sides of the rubber industry." A warm welcome can be given to this second volume, with its promise of still better things for the future.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Dyestuffs (Imports)

Replying to Mr. Hogge's enquiry as to imports of dyes and dyestuff materials during 1921, 1922 and 1923, and what proportion came from Germany, Mr. Lunn gave the following particulars :—

		Total imports Cwts.		Amount consigned from Germany Cwts.
Coal-tar dye intermediates	1921	4465	..	1721
including aniline oil and	1922	41	..	10
salt, and phenyl glycine)	1923	1349	..	267
Finished coal-tar dyestuffs	1922	57,5[illegible]	..	33,960
	1923	56,157	..	41,651
	1921	97,068	..	218
Dyeing extracts	1922	147,860	..	258
	1923	121,299	..	301
	1921	293	..	—
Indigo, natural	1922	1305	..	—
	1923	757	..	—
	1921	6428	..	—
Raw dyeing substances,	1922	10,450	..	—
other than dyewoods	1923	16,480	..	—

Gas Mantles

Answering Mr. Foot, Mr. Webb said that an application for the appointment of a committee under the Safeguarding of Industries Act (Depreciated Currency) to consider the removal of the 33⅓ per cent. duty imposed on imported gas mantles, had been received, but that he was awaiting further information for which the applicants had been asked.—(Mar. 11.)

Empire Production of Sugar

Mr. Webb said that the output of sugar in 1923-24 within the British Empire, estimated by Messrs. Willett and Grey at approximately 4,000,000 tons was produced in the following areas:—British India, 3,025,000 tons; Australia, 279,700 t.; Mauritius, 200,[illegible]00 t.; Natal, 180,350 t.; British West Indies, [illegible]8,000 t.; British Guiana, 90,000 t.; and the Fiji Islands, 35,000 t.—(Mar. 11.)

Sulphuric Ether

In a written answer to Mr. Lorimer, Mr. Webb gave the total quantity of sulphuric ether imported into the United Kingdom during 1923 as 16 gallons. This quantity was inclusive of direct imports, if any, into the Irish Free State up to March 31 of the year in question.—(Mar. 11.)

Scottish Shale Oil Industry

Replying to Mr. Clark, Mr. Webb said that he had arranged for the Anglo-Persian Oil Co. to be consulted on some of the questions raised by the deputation on February 26, concerning the future position of the Scottish shale and oil industry, but that the company had not yet had time to reply. He would like, however, to say that any danger of an early stoppage of the industry was no longer imminent.—(Mar. 11.)

Anglo-Persian Oil

Replying to Sir F. Wise, Mr. Alexander stated that during the year ending December 31, 1923, 5·4 per cent. of the imports of petroleum spirit into this country were imported direct from Persia. In addition, 320,433,790 gallons of crude oil were imported from Persia to be refined in this country.—(Mar. 12.)

COMPANY NEWS

THE BRITON FERRY CHEMICAL AND MANURE CO.

A big improvement in manufacturing profits is shown by the report of the Briton Ferry Chemical and Manure Company for the year 1923, the gross figure being £45,191, after providing for depreciation, compared with only £3014 for 1922, struck before providing for depreciation, which on that occasion required £5000. With interest and transfer fees the total available is £46,921, against £31,336 previously, when £25,677 was transferred from income-tax account. After allowing for debenture interest and redemption, placing £5000 to plant renewal account, £5000 to reserve and providing for corporation tax, there remains, including £4603 brought in, £20,212. Provision has been made for the preference dividend, including arrears, up to January 31, 1924, and the directors have recommended a dividend of 1s. per share (less tax) on the ordinary capital, being the first distribution to the ordinary shareholders since the 7½ per cent. paid for 1920.

UNITED ALKALI CO., LTD.

The profit for 1923 amounted to £352,332, and the year has been so good that although a scrip bonus of 50 per cent., requiring £300,000 from the reserve, was given in April, 1923, the ordinary dividend is to be maintained at 10 per cent.; £100,000 will be put to the reserve, and £16,000 will be added to the balance forward. Demand for the company's products has been generally satisfactory, and thus the company's works have been fairly well employed and costs have, in consequence, been further reduced. The plant and machinery have, as usual, been well maintained and all necessary repairs effected.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¼d. per lb.
Potass. Chlorate	3d.—3¼d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17— 19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In
Sod. Bisulphite Powder 60/62%	Prices reduced to £18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5¼d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide	4s per lb.
Carbon Bisulphide	£24—£28 10s. per ton according to quantity.
Carbon Black	Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 5d per lb. c.i.f.
Carbon Tetrachloride	£58 per ton, drums free.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£21 per ton.
Liquor	9d per gall. 32° Tw.
Charcoal	£7 5s.—£9 10s. per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Dull market.
Solvent	5s. per gall. 40% O.P. Dull market.
Wood Tar	£5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead	£47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7½d.—8d. per lb. Better demand, and firmer market. London prices reported up to 9d.
Crude 60's	2s.—2s. 3d. per gall. Market stronger; better demand; limited supplies.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 8d. per gall. ex works

Benzole, Pure .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 8d.—1s. 11d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d per gall.
Creosote—
Cresylic 20/24% .. 11d.—11½d. per gall. Few inquiries
Middle Oil .. .. }
Heavy .. .. .. } 8d.—9d. per gall. according to grade and district. Market
Standard Specification } easier.
Naphtha—
Crude .. .. 8d.—9d. per gall. } Better demand.
Solvent 90/160 .. 1s. 2d.—1s. 4d. } Prices show up-
Solvent 90/190 .. 1s. 1d.—1s. 3d. } ward tendency.
Naphthalene Crude—
Drained Creosote Salts £6—£8. Demand still good.
Whizzed or hot pressed £9 10s.—£12 per ton. Not much inquiry.
Naphthalene—
Crystals .. .. £14 5s. per ton. Prices reduced.
Flaked .. .. .. £14 5s. per ton. Prices reduced.
Pitch, medium soft .. 65s.—70s. per ton. Better demand for prompt and forward delivery. Prices hardening.
Pyridine—90/140 .. 17s.—17s. 6d. per gall. More demand at still higher prices.
Heavy .. 11s.—12s. Fewer inquiries.

INTERMEDIATES AND DYES

Business in dyestuffs is maintained, but without much improvement. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 10d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 4d. per lb. Steady demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4¾d.—5½d. per lb. Demand moderate.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 3d. per lb. d/d.
Monochlorbenzol .. £63 per ton.
α Naphthol .. .. 2s. 5d. per lb. d/d.
β Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 4½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 4d. per lb. d/d.
Nitrobenzene .. .. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. 11¾d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol .. 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 2d. per lb. d/d.
p-Phenylene Diamine .. 10s. 6d. per lb. 100% basis d/d.
R. Salt .. .. 3s. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 6d. per lb. 100% basis d/d.
o-Toluidine .. .. 7d.—8d. per lb.
p-Toluidine .. .. 3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine .. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is dull and values generally lower.

Acid, Acetic 80% B.P. .. £52 per ton.
Acid, Acetyl Salicylic .. 3s. 6d.—3s. 7d. per lb. Weaker tendency continues on a quiet market.
Acid, Benzoic .. .. Commercial acid, 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. 6d. lb.
Acid, Boric B.P. .. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric .. .. 18s.—20s. per lb. Business normal.
Acid, Citric .. .. 1s. 6d. per lb., less 5% for ten lots. Market extremely firm. Upward tendency.
Acid, Gallic .. .. 3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst... 6s. per lb., for 28 lb. lots.
Acid, Salicylic .. .. Market uncertain. Prices quoted from 2s. 6d. per lb. down to 1s. 10d. for ton lots.
Acid, Tannic .. .. 3s. 0d. per lb. for B.P. quality.
Acid, Tartaric .. .. 1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol .. .. .. 9s. per lb. d/d
Acetanilide .. .. 3s. per lb. Weaker. Offers are being made down to 2s. 10d. to stimulate the demand.
Amidopyrin .. .. 13s. 6d. per lb. Demand negligible
Ammon. Benzoate .. 3s. 9d. per lb. English make.
Ammon. Carbonate B.P.. £37 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make.
Barbitone .. .. 16s. per lb. Weak market.
Benzonaphthol .. .. 6s. 3d. per lb. Firmer.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides— Per lb.
Potassium .. .. 9½d.—10d. } English make.
Sodium .. .. 9½d.—10d. } No alteration of
Ammonium .. .. 10½d.—11d. } any moment.
Foreign prices are somewhat unsteady. A lot of damp sodium bromide is being offered.

Calcium Lactate .. .. 2s. 6d. per lb. for best English make. This is cheaper than the Continental product of the same quality. Indifferent qualities are offered down to 1s. 9d. lb.

Chloral Hydrate .. .. 3s. 9d. per lb.

Chloroform .. .. 2s. per lb. for cwt. lots.

Cresote Carbonate .. 6s.—6s. 6d. per lb. Little demand.

Guaiacol Carbonate.. .. 13s. per lb. for small stocks available.

Hexamine .. .. 3s. 9d. per lb. for foreign makes. Weaker. Large supplies available.

Homatropine Hydrobromide .. .. .. 30s. per oz.

Hydroquinone .. .. 3s. 9d. per lb. Foreign make.

Iron. Ammon. Citrate, B.P. 1s. 11d.—2s. 3d. per lb., according to quantity.

Magnesium Carbonate—
- Light Commercial .. £36 per ton net.

Magnesium Oxide—
- Light Commercial .. £75 per ton, less 2½%.
- Heavy Commercial .. £26 per ton, less 2½%.
- Heavy Pure .. .. 2s.—2s. 6d. per lb., according to quantity. Steady market.

Menthol—
- A.B.R. recryst. B.P. .. 60s. per lb. Market firmer.
- Synthetic .. .. 26s.—35s. per lb., according to quantity. English make. Steady demand.

Mercurials—
- Red oxide .. .. 4s. 9d.—4s. 10d. per lb.
- Corrosive sublimate .. 3s.—3s. 1d. „
- White precip. .. .. 4s. 1d.—4s. 2d. „
- Calomel .. .. 3s. 5d.—3s. 6d. „

Methyl Salicylate .. 2s. 7d.—2s. 9d. per lb. for carboys. Slightly easier.

Methyl Sulphonal .. 24s. per lb. Scarce.

Paraformaldehyde .. 3s. 6d. per lb., without much inquiry.

Paraldehyde .. .. 1s. 4d.—1s. 8d. per lb. in free bottles and cases.

Phenacetin .. .. 6s. 6d.—7s. per lb. Dull.

Phenazone .. .. 7s. 6d. per lb. for cwt. lots. Spot prices much lower than forward offers.

Penolphthalein .. .. 7s. 3d.—7s. 6d. per lb. Firm.

Potass. Bitartrate—
- 99/100% (Cream of Tartar) .. .. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.

Potass. Citrate .. .. 1s. 8d.—2s. per lb.

Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.

Potass. Metabisulphite .. 7½d. lb., 1-cwt. kegs included.

Potass. Permanganate—
- B.P. Crystal .. .. 8¾d.—9d. per lb. carriage paid. English make.
- Commercial .. .. 8d.—8¼d per lb. carriage paid. English make.

Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.

Resorcin .. .. 6s. 3d. per lb.

Salol .. .. 3s. 9d. per lb. Price fluctuates.

Silver proteinate .. 10s. per lb.

Sod. Benzoate, B.P. .. 3s. 3d. per lb. In more plentiful supply.

Sod. Citrate, B.P.C., 1923 1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.

Sod. Hyposulphite—
- Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.

Sod. Nitroprusside .. 16s. per lb. Less for quantity.

Sod. Potass. Tartrate (Rochelle Salt) .. 76s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.

Sod. Salicylate .. .. A weak market with various prices quoted. Powder 2s. 7d.—2s. 10d. per lb. Crystal at 2s. 7d.—2s. 11d. per lb.

Sod. Sulphide—
- Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.

Sod. Sulphite, anhydrous £27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.

Sulphonal.. .. .. 18s. 6d. per lb.

Tartar Emetic .. .. 1s. 4d. per lb.

Thymol .. .. .. 13s. 3d.—14s. per lb. for good white crystal from ajowan seed. Somewhat cheaper than of late.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	13s. 6d. „
Amyl Acetate	3s. „

TRADE NOTES

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during February has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 445, of which 372 were from merchants or importers. To these should be added 35 cases outstanding on February 1, making a total for the month of 480. These were dealt with as follows:—Granted, 369 (of which 344 were dealt with within seven days of receipt). Referred to British makers of similar products, 72 (of which 52 were dealt with within seven days of receipt). Referred to reparation supplies available, 22 (all dealt with within two days of receipt). Out-standing on February 29, 1924, 17. Of the total of 480 applications received, 418, or 87 per cent., were dealt with within seven days of receipt.

Trade Information

Dyestuffs.—What magic there is in this simple word! And the British Dyestuffs Corporation has done its best to show something of this magic in a tastefully produced series of booklets, illustrating its products. One series illustrates Chlorazol Dyes (Chlorazol being the group name for the Corporation's direct colours, replacing the old name "Dianol"), *e.g.*, Fast Bordeaux LK, Fast Orange R, Fast Scarlet 4BS, Drab RH, Brown PB, Diazo Blue 2B, Fast Eosine B, Black GF, Brown 2G, Fast Helio BK, each booklet containing concise instructions for use, and a table of the general properties of the particular dyestuff. A special book is issued, relating to "Chlorazol Colours on Cotton Yarn." Other booklets of a similar kind are also devoted to Ionamine B, Disulphine Green B, Solochrome Black F, Quinoline Yellow, Lissamine Green V conc., and Acronol Brilliant Blue, most of which are additions to the range of dyestuffs manufactured by the Corporation. In addition, the Corporation issues a series of larger booklets, amongst which mention may be made of those on "Basic Colours on Cotton," and on "Mordant and Non-Mordant Colours." Mention can be made of only a few of the products of the Corporation, but even this limited note would be incomplete without drawing attention to the booklet on Lake Colours, illustrated by a large number of fine colour plates and accompanied by a couple of charming colour prints, showing the effects produced by the use of these lakes. All the literature mentioned can be obtained from the British Dyestuffs Corporation, 70, Spring Gardens, Manchester.

Technical and Scientific Books.—We have received a catalogue of second-hand and new technical and scientific books, which can be obtained from W. and G. Foyle, Ltd., of 121-125, Charing Cross Road, London, W.C. 2. Messrs. Foyle render ready service in supplying out-of-the-way books, as well as current publications, and, further, are willing to supply any book in stock on approval. Their catalogue, Dept. No. 7, contains a long list of books under the headings of Brewing, Brick-making, Cements, Concrete, all branches of Chemistry, including Chemical Engineering, Colour manufacture, Dyeing, etc., Explosives, Fuels, Ceramics, Glue, India-rubber, Inks, Leather, Metallurgy, Oils and Fats, Paper, Photography, and many other subjects of interest to chemists.

PUBLICATIONS RECEIVED

The Second Annual Report of the British Cast Iron Research Association, for the Year 1922–23. *Pp.* 19. *Birmingham: The Birmingham Printers, Ltd.*, 1923.

Abridged Scientific Publications from the Research Laboratory of the Eastman Kodak Company. *Vol.* VI., 1922. *Pp.* 238+*vii*. *New York: Eastman Kodak Company*, 1923.

Manganese and Manganiferous Ores in 1922. *Department of the Interior, U.S. Geological Survey. By* H. A. C. Jenison *and* H. M. Meyer. *Mineral Resources of the United States*, 1922. *Part I. Pp.* 585—594. *No. I*: 28. *Washington: Government Printing Office*, 1924.

A Treatise on Light. *By* R. A. Houston. *Pp.* xi+486. *London: Longmans Green and Co.*, 1924. *Price* 12*s*. 6*d*.

Messrs. H. K. Lewis and Co., Ltd., have arranged to act as agents for the publications of the Chemical Catalog Company in the British Isles, and will be pleased to supply a list of these works to any enquirers. All the principal books are kept in stock.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, MARCH 28, 1924 No. 13

EDITORIAL

THE long letter from Dr. P. Fritzsche, which we print in this week's issue translated into English, is so interesting and important that it requires some comment. Dr. Fritzsche states that the view he puts forward is one animating the vast majority of German scientists. We do not dispute this claim; we in England have very inadequate means of finding out the opinions of the vast majority of German scientists, and we have no reason to doubt that Dr. Fritzsche is right in claiming to speak for this majority. He asks us a question about the Boer War; our answer is that a great many people in this country thought the Boer War was a mistake and that the British policy at that time was mistaken; they did not hesitate to publish that opinion, and we do not recall that any important manifesto supporting the British policy was ever published by a body representing the science of this country. We have no wish to discuss pure matters of history, and we do not agree with Dr. Fritzsche's views as to the origin either of the Franco-Prussian War or of the late war, but this is not the place to argue the matter or to explain our reasons. We are concerned with the future of international chemistry, not past history or past politics. That a spokesman of German men of science should state that in 1871 France was allowed to escape with very mild peace conditions and that the damage to France in 1914-1918 was well merited, seems to us not likely to conduce to a very speedy reconciliation. We wonder if Dr. Fritzsche saw Chauny immediately after the war; we did, in the spring of 1919, and the impression left on our mind is still vivid. If German men of science think that this piece of destruction was well merited, we have no more to say. Dr. Fritzsche, who compares Germany in 1914 to a harmless passer-by attacked by robbers, is not likely to value very highly the opinions of one of the robbers, whether France or Britain.

* * *

It seems fairly obvious from Dr. Fritzsche's letter that German men of science on the whole approve of the destruction in the North of France and in Belgium, and that their feeling towards their neighbours is one of dislike perhaps tinged with a little contempt. We confess that we have heard from friends who have visited Germany since the war that many people in that country believed that Germany, a harmless, good-natured country, was in 1914 attacked by a gang of robbers, and that this country and Belgium were accomplices to this scheme. But we did not imagine that German men of science, well educated and gifted with the art of weighing evidence and arriving at a logical conclusion, could in this year 1924 adhere to such an opinion. The German men of science, believing as they do in the view put forward by Dr. Fritzsche, are not likely to desire any cordial relations with the men of science in the great majority of other countries. Our Belgian friends will not for some considerable period of time acquiesce in the view that the treatment of Belgium by Germany was well merited, and we think that it will be equally difficult to convince some of the scientific men, even in the countries which were neutral during the war, that this action was particularly creditable to Germany. However, if the German men of science are satisfied on this point, the other men of science in the world can remain dissatisfied. We fear that Professor Noyes has a long task before him in attempting to promote kindlier feelings among chemists in all countries. Dr. Fritzsche's letter is of considerable value in letting the whole world know the attitude of German men of science, and his obviously sincere statement is a definite view which can be recognised by all who read his letter.

* * *

The jubilee of the Physical Society, which has just been celebrated so brilliantly, tempts one to look back on science generally and wonder at the progress made these last fifty years. Physics at one time included all natural knowledge; thus Aristotle included all nature in his "Physics," and a trace of this conception still exists in the chairs of natural philosophy at some of our universities. Centuries passed before the allied sciences of chemistry, geology, botany and zoology began to be considered as separate studies, and then physics

itself began to be divided up, as the new phenomena of astronomy, meteorology, magnetism became known. For a time physics was limited almost to the laws of motion, but it has since more than made up for any past restrictions by invading many other fields of activity, including our own field of chemistry. Many years ago we actually heard Sir Ernest Rutherford say that he did not know where the dividing line between physics and chemistry was, and nowadays we know still less. People who were apparently immersed in placid domains of "pure" chemistry and who only appeared at times before learned societies with syntheses and analyses of organic compounds of the greatest complication, matched only by their names, now appear as familiars of Bohr, Zeeman, Michelsen, Langmuir, and many others who delve into the structure of matter. In this very issue we print two articles, worthy of the closest attention, that show how indefinite the border line is, if there is one. What, one wonders, does Prof. Armstrong think of it all; and where is the "purity" of chemistry and, indeed, of any science nowadays?

* * *

How calm and peaceful was the world a hundred years ago! It is true that another great war had just ended, but think how small text-books were in those days. Cavendish, Rumford and Watt were just dead; Humphry Davy was developing his safety lamp and making arc lights; Dr. Thomas Young was objecting to Newton's theory that light consisted of little bodies travelling "with an eel-like motion," and saying "how amusing and popular" were the external phenomena of electricity; Oersted and Ampère were playing to such good purpose with magnets: and Wollaston had discovered but not comprehended the Fraunhofer dark lines. And March 12, 1824, marks the birth of Kirchhoff, who was destined to gather up the scattered phenomena of spectrum analysis and become the founder of the "far-reaching science of celestial chemistry." Celestial it is in its beauty, but familiarity has robbed it of some of its glamour. Kirchhoff's work with Bunsen was done somewhere about 1860, and 14 years later Prof. Guthrie founded the society for the advancement of physical science, whose jubilee has now been so worthily celebrated. And our own Society will attain its jubilee in eight years! But for the present we have the Annual Meeting and several other matters to think about.

* * *

Our correspondence column this week provides us with other editorial comments. The status of chemists who are not qualified to become Fellows of the Institute is not an easy problem to solve. We have published in the Journal of the Society of Chemical Industry some letters which, in places, criticise the Institute, a body with whom the Society works cordially. We see no reason why our correspondents should not criticise the Institute, the Society, or even, if they think fit, the Royal Society or the intellectual department of the League of Nations. Letters from critical individuals are printed with no hall-mark of editorial approval; they are the spontaneous effusions of those who have something to say, and choose our columns as their medium. We make this explanation lest any readers fancy that an official publication such as our Journal should exclude any statements which reflect on the aristocracy of the chemical world. Since the days of Milton we imagine no one considers that any useful purpose is served by unduly restricting the liberty of individuals to disclose their views. In every association which possesses a set of rules some arbitrary line must be drawn which inflicts hardship on those who are excluded by it. A fixed subscription, a qualification, residence in a particular place, nationality, and all similar tests exclude people who are on the border line and resemble very closely those admitted within the fold. The remedy, probably the only remedy, is the due recognition of this fact. Mr. Winston Churchill is very nearly a member of Parliament, and his political utterances will be very nearly as valuable as those put forward by the actual members. The man who just escapes the liability for super-tax is nearly as wealthy as he who pays it. Many a virtuous chemist has failed to secure a C.B.E., many a bold bad man has been kept out of a baronetcy by someone with a better claim to the title and estates. We recommend our correspondents to reflect on the philosophical views of that four-footed animal who concluded that the great length of the vascular bundles through which the sap had to flow, and the poor opportunities for photo-synthesis, necessarily tended towards the impoverishment of the grape.

* * *

The Report on Vitamins of which a second edition has just been published, appears to contain matter of interest to us all. The stability of some of the vitamins seems to be quite extraordinary. The schoolboy absorbs in cod-liver oil vitamins which the cod extracts from the plankton of the sea. The small animals which compose the plankton derive their vitamins from the microscopic organisms known as diatoms. Where the diatoms obtain their vitamins is not explained, but it seems hardly probable that they make it by some synthetic process. We imagine that small quantities of it are absorbed by the diatom from something that it feeds upon, and that the vitamin increases when the conditions are suitable. If we remember the life-history of the diatom correctly it has a siliceous skeleton which does not grow in size, it is not like the skeleton of a lobster or an oyster. And the next generation of the diatom consists of slightly smaller organisms equally limited in their powers of growth. One might suppose from this that the breed of the diatom is steadily degenerating, but this seems not to be the case. As we are on the subject of natural history we are interested to see some recent work on the occurrence of snails on soils of varying acidity. It is not the ordinary snail preying on vitamin-producing herbs in the garden which is the subject of this memoir, but the pond-snail, a parasite of which is the liver-fluke, which kills so many sheep. The price of mutton is a function of the acidity of the soil, and of the occurrence of pond-snails and some other variables.

ATOMIC STRUCTURE

By Dr. J. D. MAIN SMITH

In Bohr's scheme of the structures of the atoms of the elements, the division of the extra-nuclear electrons into groups, and the subdivision of the groups into sub-groups, is determined by two quantum numbers, an *azimuthal* quantum number governing the eccentricity of the elliptical orbit of an electron rotating about the nucleus, and a *radial* quantum number, such that the sum of the radial and azimuthal quantum numbers determines the major axis of the orbit, and, consequently, the energy of the electron in the orbit. If k be the azimuthal quantum number, and n be the sum of the azimuthal and radial quantum numbers, the energy of the orbit is inversely proportional to n^2, the major axis of the orbit is directly proportional to n^2, and the latus rectum of the orbit is directly proportional to k^2. The number of different types of orbits having the same total quantum number n is equal to n. The maximum number of electrons in an atom that can possess the total quantum number n is equal to $2n^2$, and the maximum number of electrons in any one type of orbit, *i.e.*, in a quantum sub-group, is $2n$. Bohr then proposed the following scheme of structure for the elements :—

Total—										
Quantum number ..	1	2		3			4			
Number of electrons	2	8		18			32			
Subgroup—										
Quantum numbers..	1_1	2_1	2_2	3_1	3_2	3_3	4_1	4_2	4_3	4_4
Number of electrons	2	4	4	6	6	6	8	8	8	8

This scheme, however, does not conform to the spectral evidence on which alone the scheme of quantum groups claims to be deduced. It is certain that the 2 quanta group or L level consists of at least 3 levels, the 3 quanta group or M level of 5 levels, and the 4 quanta group or N level of 7 levels. The emission of radiation, for example, by the sodium atom when its valency electron moves from a 3_2 to a 3_1 orbit ought on the foregoing scheme to be characterised by a single yellow line, whereas in fact the radiation consists of the well-known yellow doublet. To reconcile this and many other spectral anomalies, Bohr has recently resorted to dividing the elliptical orbits into two types, a and b, such that electron transitions only occur from a to b, or b to a, but never from a to a, nor from b to b. This device, however, invalidates the scheme of quantum *sub-groups*, by which the number of electrons in a level is equal to $2n$. The Bohr sub-groups can therefore no longer be maintained as integral portions of atomic structure.

The chemical evidence, on which Bohr partly based his theory, consisted almost entirely of the general properties of the elements as disclosed by the periodic classification. This evidence can be regarded as supporting any scheme of atomic structure by which the electrons are divided into groups of 2, 8, 18, and 32. The detailed structure of the atom requires a much closer acquaintance with the specific properties of each element, and these properties can be shown not merely not to support Bohr's detailed scheme, but like the spectral evidence, to controvert it. This evidence, for example, involves that the second periodic group (from Li to Ne) must be subdivided into two groups of two electrons each and one group of four electrons, that the third periodic group must be subdivided in precisely the same way as the second, and that the fourth periodic group must extend from K (19) to Kr (36), and that the fourth group of electrons is not added to between Sc (21) and Ga (31). The chemical evidence further indicates the creation of a new group at titanium (22), and of yet another new group at manganese (25), the new groups when completed having 4 and 6 electrons respectively. The structure of the scandium ion is, consequently, 2,224,224, the structure of the chromous ion, 2,224,22404, and the structure of the cuprous ion, 2,224,22446. Similar evidence of similar structure is furnished by the two groups of transition elements, from Zr (40) to Ag (47), and from Ct or Hf (72) to Au (79), each of these transition groups containing eight elements succeeding a tervalent element. The evidence furnished by the rare-earth transition group is much less certain, but indicates that the first formed groups as in Xe (54) and the La ion persist, and that the additional electrons go to form two new groups of 6 and 8 electrons, respectively, the samarous ion having the structure, 2,224,22446,2244606,224, and the lutecium ion having the structure, 2,224,22446,2244668,224, this transition group thus consisting of fourteen elements also following a tervalent element.

The rules discernable from these structures are that the number of sub-groups in a quantum group is $2n-1$, the number of electrons in a quantum group is $2n^2$, and the number of electrons in a sub-group is $2k$, every sub-group possessing *radial* quantum number being divided into two equal groups differing slightly in total energy. It consequently follows that the number of levels in the various quantum groups is 1, 3, 5, and 7, for the quantum numbers 1, 2, 3, and 4, as required by the spectral evidence. It may further be inferred that the 5 and 6 quanta groups would contain a maximum of 9 and 11 subgroups, being made up of 22446688 10, and 22446688 10 10 12 electrons respectively.

The foregoing scheme differs from Bohr's chiefly in the number of electrons in the sub-groups having radial quantum number, the sub-groups having the whole of their energy in the azimuthal quantum being identical with those in Bohr's scheme. The latter, however, is not compatible with the detailed properties of specific elements, whereas the former is deduced on no other grounds than the chemical idiosyncracies of individual elements. To take one of the simplest cases in chemistry, the existence of carbon monoxide is inexplicable in Bohr's scheme, but follows from the foregoing scheme.

In devising the scheme account has been taken, not merely of the properties of the elements as disclosed by their valency, *i.e.*, capacity for oxidation or reduction, but also by their residual affinity as disclosed by their co-ordination compounds. One of the chief inferences to be drawn from the scheme is that the bond between two non-ionisable atoms consists of one electron, except in a few instances where the chemical properties indicate a double-bond, two electrons then being assigned to the junction between two atoms. This inference alone is possible for the elements

possessing the co-ordination number of six in the third and fourth periodic groups, for the groups can accommodate only one sub-group of six electrons. Similarly this inference is alone possible for the elements possessing the co-ordination number of eight, for the completed group having the highest quantum number possesses only one sub-group of eight electrons. For the elements of the second periodic group no such inference is imperative, and it is conceivable that a pair of electrons may function in the chemical bonds between such atoms as carbon, nitrogen and oxygen. The bulk of the evidence of inorganic chemistry, at least, is, however, opposed to the idea that more than one electron invariably functions in a single bond. The existence of triatomic hydrogen, the positively charged diatomic hydrogen molecule, the hydroborons, nitric oxide, nitrogen di- and tetroxides, and chlorine dioxide, is readily explicable on the ground that the chemical bond is identical with one shared electron. The existence, on the other hand, of elements with diatomic molecules, such as F_2, involves the acceptance of the idea that a chemical bond must sometimes consist of two electrons, and it may be inferred that the single bonds between carbon atoms in organic chemistry frequently consist of dielectronic junctions. These considerations enable the following definitions to be made—positive valency is numerically equal to the electrons contributed by an atom, by ionisation or by sharing, to the structure of another atom, and negative valency is numerically equal to the electrons acquired by one atom, by ionisation or by sharing, from another atom; negative residual affinity is the capacity of an atom to acquire electrons by sharing with an atom having valency already operative, and positive residual affinity is the capacity of an atom, having valency already operative, to contribute electrons by sharing with another atom; the co-ordination number of an atom is equal to the number of other atoms with which electrons are shared. From these definitions it follows that the co-ordination number of an atom has no necessary maximum, and is determined only by the number of atoms possessing residual affinity that can be accommodated at the surface of a central atom. It may be inferred, however, that the most stable structures will be obtained only when such co-ordinated atoms contribute to the central atom a number of electrons equal to the maximum number that can be accommodated in the sub-group next to that already containing a maximum number of electrons. The cases of two typical co-ordinating elements illustrate the points. The chromous ion has the structure 2,224,22404, one of the 3_2 groups possessing none of its four possible electrons. The addition of $6NH_3$ groups, however, completes the structure by contributing six shared electrons, forming the groups 2,224,22446. On oxidation to the chromic ion with the structure 2,224,22403, the addition of $6NH_3$ groups gives the structure 2,224,22436. In this case one of the 3_2 groups is incomplete and the complex is consequently less stable than in the case of the chromous complex. The three electrons in the 3_2 sub-group can, however, be arranged in the structure with a symmetry scarcely inferior to that of four electrons, owing to the fact that the orbits of the electrons of the second 3_2 group do not diverge very greatly from circular orbits, the three electrons having their orbits in the three octahedral planes of symmetry perpendicular to the three tetragonal axes, the six 3_3 electrons having their orbits in the six planes of symmetry perpendicular to the six digonal axes, and the eight electrons in 3_1 and 3_2 elliptical orbits having their axes coincident with the eight directions of the four trigonal axes. The groups in the chromous complex have four 3_1 electrons in orbits with axes coincident with the four tetrahedral trigonal axes of the inner 2 quanta group, the eight electrons of the 3_2 groups having the axes of their elliptical orbits coincident with the eight directions of the four octahedral trigonal axes, the six 3_3 electrons as in the former case having their orbits in the six planes of symmetry perpendicular to the six digonal axes.

The cobaltous ion has the structure 2,224,22425. As the 3 quanta groups are largely filled, co-ordination can take place only in the 4 quanta groups, the maximum number of electrons being that found in the next transition group, *i.e.*, six as in the Ag ion. Smaller co-ordination numbers should exhibit greater stability, with a maximum stability at 2, the number of electrons possible in the first 4_1 group. This is the known order of stability of cobaltous complexes. On oxidation to the cobaltic ion, with the structure 2,224,22424, a symmetrical structure can be obtained with six additional electrons from $6NH_3$ groups only by rearrangement of the 3_3 and 3_3 electrons, the structure becoming 2,224,22446,2, the 3 quanta group having its complete quota of electrons, and the next sub-group, 4_1, having its complete quota of 2 electrons. The symmetry of the structure is identical with that of the chromous complex, with the addition of two electrons in highly elliptical orbits having their orbital axes coincident with those of two of the less eccentric 3_2 orbits, and emerging from the atomic surface in the space between two sets of three of the six NH_3 groups, by which they are sterically protected from approach of and reaction with other atoms as valency electrons. To this high degree of symmetry is to be ascribed the great stability of the cobaltic complexes as compared with the unco-ordinated cobaltic ion and the complexes of other elements of this transition group except chromium, for which, as already indicated, a similar symmetry is suggested and similar stability exists.

The following tables indicato the atomic structures involved at the various critical points in the periodic classification :—

Dr. W. C. White has died of illness contracted some years ago whilst erecting an oil-extraction plant in Bombay. During the war, Dr. White, who was an authority on shale oil, did valuable work at the Gretna Munitions Factory.

COUNT L. M. HILAIRE BERNIGAUD DE CHARDONNET

The death of Count L. M. Hilaire Bernigaud de Chardonnet closes a career of singular devotion to technical ideal. Born at Besançon in 1839, and trained at the Ecole Polytechnique, he left that Institution (1861) well-equipped for pioneer research work.

Early investigation of the absorption of ultra-violet light by growing plants, and an extension to human physiology in connexion with diseases of the eye brought him into contact with the Biological School and there is no doubt that the well-known work of Pasteur on the silkworm fixed his attention and directed his imagination in the line of what proved to be his life work.

The great Réaumur, as early as 1734, in a work on the natural history of insects categorically forecasts the possibility of "Artificial Silk." There appears to have been no result from this until 1855, when a certain Audemars of Lausanne patented the manufacture of a product which he calls "Artificial Silk." This appears to be based on a curious mixture of cellulose nitrate and caoutchouc, but no result of this invention can be traced.

Chardonnet, it appears, worked in the period 1878-1884, in which year he deposited with the Academy of Sciences a *pli cacheté*, which is a specification of the definite invention, even of the details of projection of his collodion through an orifice of 1·10 mm. dimension into a bath of water which solidified the thread. He describes the silky aspect and indicates the tenacity of thread in terms of breaking strain, 30 kilos. per square mm. of section.

Following this in the Exhibition of 1889, in the machinery section, Chardonnet organised a practical demonstration of the manufacture, for which he received the Grand Prix. With the increasing recognition of the possibilities of the invention his friends of Besançon induced him to identify the new industry with his birthplace, and the necessary capital for the pioneer factory was found by local financiers. From this date onwards the development of the actual industry was rapid, and the company reached in 1900 a position of very great financial success.

As is well known, the production of thread from cellulose nitrate is associated with exceptional difficulty, and the success of the Chardonnet group in overcoming these difficulties rather encouraged inventors to explore the possibilities of the alternative solutions of cellulose derivatives. The subsequent history of the matter which was rather in favour of the cuprammonium product, and later, still more in

favour of the product made from viscose, are matters of common knowledge.

The recognition of the pioneer work of Chardonnet has been world-wide. In this country the definite recognition of this achievement is in the award by the Society of Dyers and Colourists (1914) of the Perkin Medal. Chardonnet was the recipient of many other honours; he was elected Member of the Institute in 1918.

As stated in our opening words, this is a career of a typical "genial" inventor, not a mere empiric, but of a student seeking by the strict methods of science, to realise a technical ideal.

Chardonnet died at the age of 84, and within a few weeks of his death filed a new patent for a mechanical improvement of his spinning apparatus, for which the drawings were prepared by his own hand. It is clear, therefore, that in this case the extraordinary difficulty of his career, only known to those who are aware of the inner history of "Artificial Silk," in no sense impaired his faculties.

The writer had only occasional personal contact with Chardonnet, and therefore cannot speak further than of the impressions so obtained, which were those of a genuine enthusiast, great clarity of vision, and entirely honest. In Hilaire de Chardonnet we cordially recognise a type of pioneer peculiarly French, and as in other notable instances France sows the seed and raises the tender plant against enormous difficulty, preparing the larger harvest perhaps for those who come and follow after.

C. F. Cross

EXPLOSIVES AND THERMITS

By A. MARSHALL

An explosive has been defined as a solid or liquid substance or mixture of substances which is liable, on the application of heat or a blow to a small portion of the mass, to be converted in a very short interval of time into other more stable substances largely or entirely gaseous.[1] There are some apparent exceptions to this definition. It has for instance been pointed out by A. Slingervoet-Ramondt[2] that a mixture of aluminium powder and potassium chlorate behaves as an explosive and that silver acetylide detonates when ignited although the reactions give no gaseous products:

$$2Al + KClO_3 = Al_2O_3 + KCl$$
$$C_2Ag_2 = 2C + 2Ag.$$

A mixture of magnesium powder and potassium perchlorate has indeed been used on a considerable scale in the British service under the name of Ophorite as a bursting charge for incendiary shell, smoke bombs, etc.[3] It has however been shown by J. Eggert and H. Schimank that the destructive effects produced by silver acetylide are due to the presence of impurities such as silver nitrate and silver oxide.[4] When prepared by passing acetylene into a solution of silver nitrate in nitric acid the acetylide may contain as much as 43 per cent. of the nitrate and the product is as violent as silver azide and more so than mercury fulminate, and the evolution of gas is almost as great. If made by passing acetylene into an ammoniacal solution of silver nitrate the acetylide is much purer but even then contains some 14 per cent. of oxide, and the effects are much smaller. These effects are therefore due to the evolution of gas by the impurities intensified by the extreme rapidity of the reaction.

The comparatively mild explosions of mixtures of chlorates and perchlorates with such metals as aluminium or magnesium appear to be due to the evolution of gaseous oxygen. A proper investigation of these apparent exceptions therefore only confirms the accuracy of the above definition of an "explosive." It should, however, be borne in mind that it is possible to have an explosion even when no explosive is present. An explosion is said to occur whenever gas or vapour expands or generates pressure with sufficient violence to produce a loud noise. So one may have an explosion of a cylinder of compressed gas, a steam boiler or a pneumatic tyre, or again of a mixture of air and a combustible vapour such as that of petrol.

Schimank has defined a thermit as a system which is capable of undergoing an endothermal chemical reaction with great or comparatively great velocity without giving gaseous end-products.[5] Pure silver acetylide would therefore be a thermit, but the ordinary product contains impurities which convert it into an explosive. It is evident that the reaction spreads through a column of this substance with a speed equal to that of the ordinary detonating explosives, that is several thousand metres per second. The thermits of commerce, such as a mixture of aluminium powder and iron oxide, react with a much lower velocity, probably only a few metres per second. If they were rapid there would generally be a sufficient proportion of gas-forming impurity present to convert them into explosives. With a slow mixture the generation of gas is too gradual to cause an explosion and the consequent scattering of the material. A better definition of a thermit would therefore be "a substance or mixture capable of undergoing an endothermal reaction with sufficient velocity to prevent the reaction dying out, without giving off sufficient gaseous products to scatter the material." If the velocity of reaction be of the same order as that of a high explosive and the material be not specially pure, it will in most cases behave as an explosive and not as a thermit.

THE MECHANISM OF MOLECULAR ACTIVATION

By R. G. W. NORRISH, B.A.

It is now generally admitted that, in order to explain the high temperature-coefficient of chemical reactions we must have recourse to some hypothesis of molecular activation, such as that originally suggested by Arrhenius.[1] According to this view only a small percentage of the molecules of a reacting substance are in a reactive state, and become so by the absorption of a certain quantity of energy.

It can easily be shown that such an hypothesis leads to an expression for the temperature coefficient η of a reaction.

$$\eta = \frac{k_1}{k_2} = e^{\frac{-(q_a + q_b + --)}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)}$$

where k_1 and k_2 are the velocity constants, at absolute temperatures T_1 and T_2 differing by 10°, and q_a, q_b, etc., are the energies of activation per gram molecule of each molecular species, termed by McG. Lewis the critical increments of the substances.

It should be noted that if a molecule becomes activated in stages, then the q measured from the temperature coefficient will be that referring to the slowest of the processes of activation proceeding.

Many attempts[2] have been made in recent years to provide a universal theory of molecular activation on the basis of the absorption of temperature radiation in equilibrium with the system, in terms of quanta. The authors of the radiation theory write

$$q = NhV$$

where V is the frequency of the active radiation, N the Avogadro number and h Planck's constant. From a knowledge of the temperature coefficient of a purely thermal reaction it is thus possible to calculate the frequency of the activating radiation. The substance in question should thus show an absorption band in the region of the spectrum corresponding to V, and the reaction should also be photochemically accelerated by subjecting the reactants to light of the requisite wave length. Neither of these predictions have in general proved true, though there is no reason why the radiation theory in a restricted sense should not continue to be regarded in the light of a working hypothesis.

We will now consider briefly an alternative method by which the problem of chemical reactivity may be attacked, which may be termed the hypothesis of kinetic activation.

A calculation of the increase in number of molecular collisions per second with temperature, has shown it to be totally inadequate to explain the high temperature coefficient of a reaction. If,[3] however, we regard only those molecules of the substance which have a kinetic energy of translation exceeding a certain limiting value, as being potentially active, we obtain an expression for the temperature coefficient of the right form, since their number increases exponentially with temperature. Thus we may imagine the molecule of phosphine to decompose when the energy of its rotational degree of freedom passes a certain limiting value. As a parallel conception for a bi-molecular reaction, we may imagine reaction between two molecules to occur only after a collision in which a minimum momentum exchange has been effected. This would mean that a minimum force of distortion must be exerted between the colliding molecules before reaction could occur, and it follows from the mathematical treatment that the work done during the exercise of this minimum force of distortion is equal to q, the critical increment of the reaction.

There is, however, one point which requires mention,[4] namely, that it follows as a mathematical necessity, in order to preserve the Maxwellian distribution of velocities, that energy absorbed in the activation of molecules, either from the kinetic energy set free on collision, or from the kinetic energy of vibration, should take an appreciable and calculable time to pass from the one form to the other. This time is equal to or greater than the so-called period of relaxation, and its existence warns us that we are dealing here with something outside the Newtonian mechanics. It is probable that at this point, that is in the transfer of energy from the outside to the inside of the molecule, the quantum relationships of the atom enter in.

Upon this kinetic theory of activation we may regard the catalytic effect of such substances as water vapour, ammonia, polar surfaces, and solvents in general as a preliminary weakening of the molecular system of the reacting substance, effected by close molecular association, and thus rendering lower the value of the critical increment of activation necessary to render the molecule completely unstable.

An example[5] of this is provided by a mixture of ethylene and bromine, which when dried and placed in a vessel of non-polar paraffin walls reacts only extremely slowly at 0° C., whereas at higher temperatures, when an appreciable number of favourable impacts occurs, it reacts in spite of these conditions at much greater velocities. When, however, the gases are damp, or polar walls of stearic acid are substituted, the velocity of combination at 0° is very great, the critical increment of activation, having been lowered by the catalysts so that molecular collisions of much lower momentum exchange are now favourable.

It would seem that the kinetic and the radiation theory of molecular activation are together sufficient to cover the broad field of chemical reactivity, and they are by no means mutually exclusive; indeed, there would seem no reason why both processes should not at times be simultaneously operative in the same chemical reaction.

That molecular activation, whether kinetic or radiational, takes place in terms of quanta seems extremely probable in view of our modern knowledge of atomic and molecular structure, and if we follow G. N. Lewis[6] in regarding activation as the displacement of the bonding electrons of the molecule to higher quantum orbits, it follows as a mathematical necessity. Thus it follows that there there must be some undiscovered process by which the external energy of vibration or collision is transferred in terms of quanta to the interior of the molecule, a process which occupies an appreciable period of

time already referred to above as equal to or greater than the "period of relaxation." With activation by radiation the process is presumably instantaneous.

In view of this reasoning it is of interest that experimental evidence is now available to show that activation is a quantum phenomenon. In our study of the various reactions which sulphur undergoes with hydrogen and with oxygen, Dr. Rideal and I[7] have shown that in all cases the critical increments of activation of the reactions are the simple multiple of a constant quantity which may be regarded as the critical energy required to displace one bonding electron of the sulphur molecule to the next higher quantum orbit.

The values of the critical increments found for the various reactions investigated are shown in the accompanying table, which is taken from our paper "On the Conditions of Reaction of Hydrogen with Sulphur, Part IV" (*loc. cit.*).

Reaction	Temp. coeff.	Critical Increment at 300° or heat of reaction per gm. mol. = c cals.	Number of free sulphur bonds produced x2 = n	Constant = c/n cals.
$\frac{1}{2}(2H_2+S_2)$ gaseous ..	2·19	51,460	4	12,865
H_2+S surface ..	1·48	25,750	2	12,875
$\frac{1}{2}(S_2\rightarrow 2S)$ gas dissoc. ..	—	50,000	4	12,500
Liq. $S\rightarrow S_2$ gas	—	28,000	2	14,000
Latent heat at 316° per gm. mol. S_2	—	23,200	2	11,600
Allotropic change of liquid S.	1·48	25,750	2	12,875
O_2+S surface A. ..	1·48	25,750	2	12,875
O_2+S surface B. ..	1·78	37,450	3	12,480

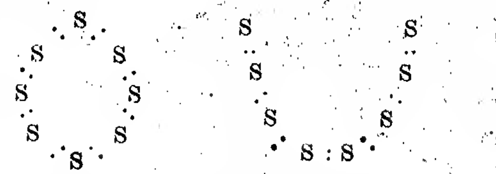
In addition we have just found that the reaction between hydrogen and sulphur vapour can be effected photochemically by ultra-violet light, composed of the wave lengths given by the mercury vapour lamp.

The critical increment 51,460 found for the gaseous reaction $\frac{1}{2}(2H_2+S_2=2H_2S)$ corresponds to an activating wave length of 2762 A.U., a wave length which may therefore reasonably be expected to occupy the head of the absorption band of sulphur in the ultra violet. This point will shortly be tested experimentally. It may be mentioned that there is a fairly strong line in the mercury vapour spectrum at 2745 A.U., which will account for the photochemical activity of mercury vapour ultra-violet light, found for the above reaction. At the same time strong lines exist also at 2536 and 3127 A.U., bracketing this supposedly active line, and since the absorption band of a vapour usually has considerable breadth, these may also be absorbed by the sulphur, without necessarily contributing to the photochemical reaction, which is probably extremely selective in character.*

* Since writing the above the attention of the author has been drawn to the work of J. I. Graham on the absorption spectrum of sulphur vapour in the ultra-violet (*Proc. Roy. Soc.*, **84A**, 311). The absorption spectrum for S_2 vapour was obtained, and consists of a band stretching from wave length 3415 A.U. to wave length 2620 A.U. showing fine structure and having its head at 2665 A.U. in close agreement with the predictions of the above work.

There is evidence (discussed at the end of our paper on the reaction of sulphur with oxygen) to suggest that the sulphur in the A and B surface relations, at least, is activated by molecular collision alone, so that if it turns out that the wave 2745 A.U. is the photochemically active agent, as seems likely, we shall have obtained evidence that the sulphur atom, whether activated by collision or by radiation, always requires a critical increment of activation which is some multiple of a constant value, a multiple depending upon the number of bonding electrons which require elevating to their higher quantum orbits.

For example the activation of the molecule S::S involves the displacement of four bonding electrons, a process which may be identical with dissociation, while the activation of the molecule (I) involves the displacement of but two electrons, to give the broken ring (II).



I II

The former of these processes involves a multiple of 4, while the latter involves a multiple of 2.

A further piece of evidence seemingly in favour of the conception of kinetic activation occurring in quanta has recently been advanced by Olson and Storch,[8] who subjected a mixture of nitrogen and hydrogen to an electron stream. Reaction commenced only when the activating electrons reached a certain minimum velocity, and thereafter as the velocity of the electron stream was increased the reaction rate increased by a series of jumps producing a step-like curve. The experimental facts seem to indicate that the nitrogen becomes activated by electron impact when this reaches a minimum value and that as the violence of the electron impact is increased, the intensity of the activation of the nitrogen molecule increases by a series of jumps corresponding to the absorption of an integral number of quanta for a given collision.

Further experiments of this relatively simple nature should throw much light on the absorbing problem of chemical reactivity which appears to be becoming slowly bound up with the wider problems of quantum dynamics.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

July 9—12

PATRON: H.M. THE KING

Preliminary information regarding this meeting was given on p. 309 of *Chemistry and Industry* for March 21.

A programme will be issued shortly.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

OFFICIAL NOTICE

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready and copies are in course of being despatched to purchasers.

Full particulars regarding the above and preceding volumes will be found on p. xiii of the Advertisement Section of this issue.

LIST OF MEMBERS ELECTED,

March 14, 1924

(continued)

Nagai, Professor Yuzaburo, Dept. of Applied Chemistry, Faculty of Engineering, Tokyo Imperial University, Tokyo, Japan. Professor of Applied Chemistry.

Pozzi-Escot, Professor Matius E., c/o Sociedad Quimico Industrial "Lima," Lima, Peru.

Ratz, Roswell D., c/o Dominion Tire Factory, Kitchener, Ont., Canada. Technical Superintendent.

Savage, Joseph, 111, Greenway Road, Runcorn. Chemist and Works Manager.

Smellie, Peter, 13, Dean Park Crescent, Edinburgh. Chemist.

Smith, Thomas A., c/o J. E. Pearse and Co., 88 to 94, Overstone Road, Northampton. Technical Chemist.

Somerville, Percy G., The National Benzole Association, Wellington House, Buckingham Gate, London, S.W. Secretary.

Taylor, Thomas, 2a, Hartington Road, Buxton, Derbyshire. Director of Chemical and Colour Works.

Weiss, Morris L., 441, Riverside Ave., Newark, N.J., U.S.A. Research Chemist.

Wait, F. G., Mines Branch, Dept. of Mines, Sussex Street, Ottawa, Canada. Chemist.

Wilkie, Arthur L., 2, Osborne Street, Sherwood, Nottingham. Analytical Chemist.

DEATHS

Bentz, Ernest (elected 1890), of Westwoodside, Wilbraham Road, Manchester, S.W. Technical Chemist. On February 20, 1924.

Chambers, Edgar V. (elected 1920), of The Manse, Lightcliffe, Yorks, Chemical Engineer. In July, 1923.

Mansfield, John F. (elected 1915), of Riverview, Devonport Avenue, Hessle, Yorks, Chemical Manufacturer. On February 15, 1923.

BIRMINGHAM AND MIDLAND SECTION

The annual general meeting was held at the Birmingham University on March 18, Dr. E. B. Maxted presiding.

Mr. George King (hon. secretary) announced that the following officers had been elected for the ensuing year:—Chairman, Prof. G. T. Morgan, D.Sc., F.R.S.; vice-chairmen, Mr. F. R. O'Shaughnessy and Dr. D. F. Twiss; hon. secretary and treasurer, Mr. G. King; Committee, G. H. Blenkarn, S. A. Brazier, W. A. S. Calder, W. T. Collis, W. C. Davis, A. E. Johnson, A. W. Knapp, Dr. A. Parker, Dr. E. B. Maxted, C. Watson, Dr. W. Wardlaw, C. E. Wood, Dr. T. J. Murray, J. C. Mann and L. M. Jones. The meeting approved the election of about a dozen associate members.

The following papers were then read:—(1) "The Fermentation of Cacao" by A. W. Knapp, B.Sc., and (2) "The Relation of the Theobromine Content of Cacao to its Fermentation" by A. W. Knapp and R. V. Wadsworth.

Mr. Knapp pointed out that there was no complete account of what precisely happened in the fermentation of cacao. Many planters could produce the kind of bean that cocoa manufacturers required, but the former had neither equipment nor the scientific training necessary to carry out successful experiments. Manufacturers definitely preferred fermented cocoa to unfermented cocoa. An attempt to find out when the theobromine first went into the shell of the bean showed that it began within 24 hours, but there was a sudden increase between 48 and 60 hours. Washing the beans did not appear to affect appreciably the theobromine content of shell or nib, a conclusion which, in respect of cacao shell, was contrary to the expectation expressed by one of the authors in a previous paper. They were satisfied from an examination of the cacao beans of commerce that theobromine passed into the shell during fermentation. Theobromine, free and combined, existed only in the cotyledons of the fresh cacao bean. The skin of the fresh bean was practically free from theobromine. As fermentation proceeded the temperature was high enough to kill the bean, and at once the liquid which permeated the bean contained theobromine. Thus theobromine passed into the shell, so that it was usual in a well-fermented bean of the "forastero" type to find from 0·8 to 2·98 per cent. of theobromine in the dry shell, practically all of which had come from the cotyledons. Hence the longer the fermentation, the less theobromine would be found in "nibs."

Dr. Maxted asked for information on the influence of a constant temperature upon the rate of fermontatiowfcadso if the distinctive aroma of cocoa could r, withoied artificially. Mr. F. R. O'Shaughnesochemical rehat the effect was on fermentation if thve in charact excluded or much restricted. Mr. R writing the above the that theobromine, if not present to the work of J. I. ht exist as a tannate. Mr. Howse ulphur va in the ble that a constituent like linalool. The formation arge a proportion of the essential oil of cocoa.

Mr. Knapp in reply said that he did not know of any work showing the influence of constant temperature, neither was he aware of an artificial produc comparable with the real article. The importance c aeration in the fermentation process could not b over-rated. He knew of nothing that contradicte the theory that theobromine might exist as a tannat

YORKSHIRE SECTION

On March 17 there was a good attendance t to hear the president of the Society, Dr. E. F. Armstrong, F.R.S., deliver an address on "Some Problems in the Chemistry of Fats and Oils"; Dr. L. L. Lloyd in the chair.

The feature of the address which marked it throughout was the skilful manner in which the facts and the most recent theories were knit together to make a connected whole. The great difficulties in manipulation were touched upon, and the speaker explained why the chemistry of fats and oils was in such a backward condition, notwithstanding their very great importance in industry. The address does not admit of condensation, but its scope will be gathered from the subjects treated, viz., the nature of the fatty acids, unsaturated and saturated, and their glycerides, the structure of the fats, the Hardy-Langmuir theory of the oil film, crystalline structure with Bragg's results, and the hydrogenation of fats. Certain biological questions were also treated.

The president suggested that some University should be equipped with the necessary accommodation and funds to carry out the laborious research needed to elucidate the many problems still awaiting solution.

BRISTOL SECTION

On March 6 the annual general meeting was held, and the following officers were elected for the coming session:—Chairman, M. W. Jones, Esq.; Vice-Chairman, Prof. F. Francis; Hon. Secretary, Arthur Marsden; Hon. Treasurer, M. W. Jones; Auditors, Dr. Bywaters and F. J. Popham; Committee, Drs. Butler and Rixon, Messrs. Gray, R. Robertson, R. P. Littler, E. Lewis, C. J. Waterfall, D. T. H. Beaton, C. M. Watkins, E. J. Holmyard. A hearty vote of thanks to the University, for the excellent facilities granted during the session, was carried with acclamation.

At the ordinary meeting which followed, a paper on "Fuel Economy Questions" was read by Mr. H. Womersley, who discussed the properties of the chief fuels and their use for raising steam, special attention being paid to the rates of combustion of coal from different areas. Thus, with similar conditions, northern coals were open and quick burning, whereas Forest of Dean coal was medium and Somerset coal slow-burning. Detailed accounts were given of the modern application of high-pressure, superheated, and exhaust steam, and it was suggested that in the near future factories using low-pressure steam would use exhaust steam from power stations. In conclusion the insulation of high-pressure mains, recording instruments for boiler plants, pulverised fuel and other points were considered, the paper leading to an excellent discussion.

CHEMICAL SOCIETY

An ordinary meeting was held on Thursday, March 20, when the President, Prof. W. P. Wynne, read a congratulatory address which the Council had presented to the Physical Society on the occasion of the celebration of its fiftieth anniversary. Further announcements were to the effect that the Faraday Lecture would be delivered by Prof. R. A. Millikan on June 12 instead of June 26, and that the Society of Chemical Industry had kindly arranged for copies of the Report on the Progress of Applied Chemistry to be available for Fellows of the Chemical Society at the reduced price of 10s.

The first paper was read on behalf of the author by one of the Secretaries :—

The action of thionyl chloride on alizarin. By Albert Green.

A contradiction of a statement previously made (December 6, 1923), that the action of thionyl chloride on alizarin gives an isomeric form of the latter substance. The product is mainly 2-acetyl-alizarin together with a small amount of unchanged alizarin, and arises from the interaction of an unstable intermediate compound and the acetic acid used in recrystallisation.

Dr. P. C. Austin then read the following paper :—

Rotatory dispersion of derivatives of tartaric acid. Part I. Methylene derivatives. By P. C. Austin and V. A. Carpenter.

By the action of formaldehyde on tartaric acid two compounds can be obtained, one of which is strongly dextro-, the other lævo-rotatory. These were prepared and examined in order to obtain further evidence on the nature of the dynamic isomerides which are present in aqueous solutions of *d*-tartaric acid of all concentrations (Lowry and Austin, *Phil. Trans. Roy. Soc.*, A. 1922, **222**, 249). Methylenetartaric acid, prepared by a modification of the method of Lobry de Bruyn and van Ekenstein (*Rec. trav. chim.* 1902, **21**, 313) was found to possess a specific rotation $[\alpha]_D^{20°} = -81°\cdot3$ for solutions of different concentrations. Its rotatory dispersion is simple, *i.e.*, it is expressed by one term of Drude's equation. Dimethylene tartrate on the other hand is strongly dextrorotatory but its rotatory dispersion is also simple. Alternative formulæ are suggested for the latter compound. It is claimed that the complex character of the dispersion of tartaric acid is due to an oscillation of the molecule between two configurations, since this oscillation is prevented by bridging across the hydroxylic groups, when derivatives of simple dispersion result.

Prof. T. M. Lowry said that the evidence which was now brought forward enabled one to obtain a clear picture of the possible isomerism, the explanation being chemical in character.

Dr. R. H. Pickard deprecated the practice of referring to the existence of dynamic isomerides of tartaric acid and its derivatives as proven when there was no evidence except that of rotary dispersion for such a statement. In collaboration with Dr. Kenyon, he had examined many cases in which measurements of rotary dispersion might be considered to point to the existence of dynamic isomerism, but he had been quite unable to find any support for this view. Further, Mr. Hunter had recently shown that rotary dispersion could not, in the present state of knowledge, be considered to possess any chemical significance whatever, and that in all probability simple rotatory dispersion did not exist. Finally, he failed to see how *X*-ray measurements of crystal structure could be considered in relation to rotatory dispersion measurements made with a substance in solution.

Prof. E. C. C. Baly said that the expression $k_1/(\lambda^2-\lambda_0^2) + k_2/(\lambda^2-\lambda_2^2)$ when written $p_1/(v_1^2-v^2) + p_2/(v_2^2-v^2)$ was similar in form to an expression employed in tidal calculations; it is thus not empirical, but has a definite physical meaning. He objected, therefore, to the use of a variation such as $[\alpha] = k_1/(\lambda^2-\lambda_2^2)-k/\lambda^2$.

Mr. H. Hunter asked how the dispersion equations for the methylene derivatives of tartaric acid had been calculated; it appeared that only two of the observations had been used for this purpose. He thought that the evidence for the existence of boro-tartaric acid in aqueous solutions of boric and tartaric acids ought to be supplemented, and outlined a method dependent on change of p_H of mixtures of the acids whereby this might be accomplished.

At this point, Prof. Lowry was invited to read the following paper :—

The rotatory dispersive power of organic compounds. Part XV. The molecular weight of ethyl tartrate and the origin of anomalous rotatory dispersion in tartaric acid and its derivatives. By T. M. Lowry and J. O. Cutter.

(*a*) The cryoscopic constant of carefully-purified formamide, melting at 2·2° is 5·16° per gram-mol. of urea in 1000 grams of solvent.

(*b*) Purified ("glacial") ethyl tartrate is unimolecular in this solvent up to a concentration of 16 per cent., the mean value of the cryoscopic constant being 5·18°. The dispersion curves for ethyl tartrate in this solvent are, however, strongly complex in character.

(*c*) The molecular weight of ethyl tartrate in benzene increases to nearly double its normal value at a concentration of about 20 per cent. In this range of concentration the rotatory power of ethyl tartrate increases up to about 10 per cent. and then decreases again.

(*d*) In ethylene bromide, the polymerisation of ethyl tartrate is more rapid than in benzene, but is accompanied by a progressive diminution of the lævorotatory power of the ester.

(*e*) Ethyl tartrate gives even higher dextrorotations in naphthalene at 70° than in formamide at 20°; but it is more strongly polymerised (50 per cent. at 9 per cent. concentration), in this solvent at 80° than in benzene at the same temperature (Patterson).

(*f*) These results are incompatible with Astbury's view that the dextrorotatory component of tartaric acid is a single molecule, whilst the lævorotatory component is a polymeride in which the structure of the crystal is in part maintained.

Prof. Lowry added that he was unable to see any valid objection to the use, from the point of view

of rotatory power, of an equation with one positive and one negative term.

The discussion was resumed by Dr. W. T. Astbury, who said that Prof. Lowry's remarks were directed against a misconception of his theory, and included the unwarranted assumption that the speaker's views regarding tartaric acid were applicable also to its esters. His own suggestion was that, granted that the dispersion is represented by the two-term Drude equation arrived at by Prof. Lowry, the *d*-term is to be associated with the carbon nucleus (irregular tetrahedron) of the molecule, and the *l*-term with the remainder which is subject to the action of various chemical and physical disturbances. As an example of physical disturbance he cited the force which is brought into play during supersaturation and crystallisation. The crystal-structure, the stable system towards which concentration and supersaturation are tending, suggests that finally the *l*-rotatory parts of adjacent molecules link up and evolve a *l*-rotatory system which completely overpowers the dextro-nucleus. These arguments could not, however, be transferred bodily to the case of another substance such as the ester. The speaker's suggestions were simply an attempt to find a basis for the two terms, assuming these to be correct, in the case of the acid; no sound general theory of anomalous rotatory dispersion exists. He was unable to ascribe any meaning to "simple" and "complex" dispersion; the former indicated only that the dispersion appears "simple" within the range examined and within the limits of experimental error. Finally, he regarded Dr. Austin's arguments, intended to correlate borotartaric and methylenetartaric acids, as fallacious, since they were based on the assumption that the methylene- and boro-groups are equivalent in their action on light; the point could be illustrated by reference to the isomorphous *d*- and *l*- rotatory potassium and ammonium sodium tartrates.

In reply, Dr. Austin remarked that Dr. Astbury had himself suggested an alternative solution of the problem of anomalous rotatory dispersion as a corollary to his work on the X-ray examination of crystals. Dynamic isomerism still offered a better explanation, since in the compounds described the 4-carbon chain persisted, although with lævo-rotation.

Mr. W. E. Garner described experiments on :—

The heat of adsorption of oxygen by charcoal. By E. A. Blench and W. E. Garner.

The heat of adsorption of oxygen on a purified wood charcoal has been determined over a range of temperatures from 18° to 450°, and for varying degrees of saturation of the charcoal surface. The charcoal, suspended in a platinum container, was heated at 900° for two hours in a high vacuum, cooled to the experimental temperature, a small quantity of oxygen was introduced into the space above the charcoal, and the rise in temperature was measured with a thermocouple. The gaseous products, carbon monoxide and dioxide, were removed and analysed; the gas pressure above the charcoal was reduced to 10^{-3} mm., a further small volume of oxygen was then introduced, and the temperature was measured as before. A third admission of oxygen was sometimes carried out in a similar manner.

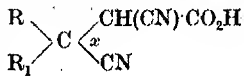
The following are typical results obtained with 4·5 gm. of charcoal:—at 18°, 1·299 c.c. gave 52 Cal.; at 199°, 1·331 c.c. gave 115 Cal.; at 283°, 1·295 c.c. gave 154 Cal.; and at 450°, 0·593 c.c. gave 224 Cal. per gm. mol. oxygen adsorbed. The heat of adsorption decreases as successive quantities of oxygen are adsorbed on the charcoal.

It is deduced that the heat of formation of stable groups of carbon and oxygen atoms on the surface increases with rise in the temperature of adsorption. This is in agreement with the experiments of Rhead and Wheeler on the thermal dissociation of the adsorption complex.

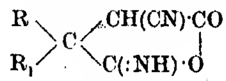
Prof. J. F. Thorpe discussed: —

Ring-chain tautomerism. Part X. Inhibited tautomerism. By F. Dickens, L. Horton and J. F. Thorpe.

When the sodium salts of the acids (I), in which the tetrahedral angle x is altered by making R, R_1 represent *cyclo*hexane,

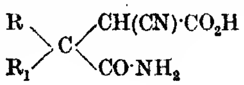


I

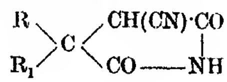


II

dimethyl, and *cyclo*heptane, respectively, are treated with mineral acids, neither of the compounds (I) or (II) can be isolated, the only substances present being the acid amides (III) and the imides (IV) :—



III

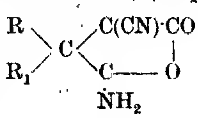


IV

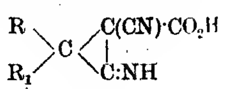
The amounts of (III) and (IV) respectively are: *Cyclo*hexane, 100%, nil. Dimethyl, 70%, 30%. *Cyclo*heptane, nil, 100%.

The entrance of the mobile hydrogen atoms to form the free carboxylic acids (I) leads at once, in all cases, to the formation of the oximino-compounds (II), but tautomerism between these substances is inhibited since, on or shortly after their formation, the oximino-compounds undergo changes in two directions :—

(i) If the deflection of the tetrahedral angle is sufficiently great, as in the *cyclo*hexane series, the amido-form (V) is quickly attained.



V



VI

(ii) If the deflection is not great enough, the imide (IV) is obtained, as in the *cyclo*heptane series.

The amino-compounds (V) are, however, unstable, and tend to pass into the isomerides (VI), in which

form they are readily hydrolysed to the acid amides (III). The mixed products in the dimethyl series are therefore due to the changes proceeding in both directions.

The experiments supply further proof that the *cyclo*heptane ring is not uniplanar.

The President congratulated Prof. Thorpe on the completeness of the investigations carried out in his laboratories.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

A meeting was held on March 4, when the President, Prof. G. T. Morgan, F.R.S., welcomed Dr. F. W. Aston, F.R.S., and recalled the lecturer's former association with the Society. Dr. Aston delivered a lecture entitled "Atomic Weights and Isotopes," and commenced by showing how the existence of isotopes modified Dalton's postulate that "atoms of the same element are similar to one another and equal in weight." The two methods by which the postulate can be tested experimentally are either by comparing the weights of individual atoms or by demonstrating that chemically identical samples of an element can have different atomic weights. The lecturer dealt with the method of analysis by means of positive rays, describing the apparatus and method of Sir J. J. Thomson and leading up to his own work on the measurement of the mass spectrographs of the elements. Various elements were discussed and the mass-numbers of their isotopes indicated. The work on the attempted separation of the isotopes of neon by distillation and the partial separation effected by diffusion experiments were discussed. Deviations from the whole number rule among the elements were then considered. Hydrogen is the oldest known exception and it has recently been shown that tin is another exception. Tin tetramethyl was used for this work, and it was shown that while the masses of the lines of tin were integral with regard to each other, yet when compared with the two strong xenon lines they gave values less than whole numbers by 2—3 parts in 1000. It is suggested that these divergencies are due to the method of packing of the nucleus. The lecturer concluded with a discussion of the spectra of isotopes and gave an account of the work of Bronsted and Hevesy on the partial separation of the isotopes of mercury by distillation in high vacua.

At the meeting held on March 17, Mr. R. L. Wormell, B.Sc., read a paper entitled "Ionisation in Non-aqueous Solvents." The lecturer showed that all liquids were capable of conducting an electric current when suitable substances were in solution. Types of conductance curves were discussed especially for solvents of low dielectric constants, *e.g.*, sulphur dioxide, methylamine and bromine. The relation between solvent power and dielectric constant was briefly indicated. The connexion between unsaturation and ionisation, and finally the conception of the solvation of ions, were described in some detail.

SOCIETE DE CHIMIE INDUSTRIELLE

The Economic Group met on February 27, under the chairmanship of Monsieur C. Drouets, director of the Industrial Property Section of the Ministry of Commerce, to hear a paper on "The General Technique of Action" by Monsieur Otlet, director of the International Institute of Bibliography of Bruxelles. Monsieur Otlet said that three orders of ideas or movements had developed under different names and had been elaborated into independent bodies of doctrine: the doctrine of administration, the doctrine of works organisation, and the doctrine of "documentation." Many facts are common to all three, such as human co-operation in the works, public services, and scientific institutions, the great part played by paper bearing writing or print in all transactions, and the use of reason and experiment to replace routine and empiricism. There was reason to ask in what measure these three doctrines, in particular "Taylorism" and the conceptions elaborated by the International Institute of Bibliography and Documentation, are of mutual assistance. Such an investigation leads to the question, is it possible to outline and elaborate a general technique of action in which should be synthesised the data and principles of the three doctrines, thus forming three parts of one whole.

Monsieur Jean Gérard followed with a paper on "The Organisation of a National Office of Chemical Documentation," in which he attempted to show that in chemistry the question of documentation was of enormous importance. Amongst the sources of documentation were printed material, unpublished reports, information on industrial and commercial establishments, and the lecturer suggested the establishment of a complete office of chemical documentation comprising seven departments. Pure chemistry; apparatus, etc., for laboratory and plant; fuels; metallurgical and mineral industries; organic industries; agriculture and agricultural industries, and economic organisation, comprising sources, markets and legislation. Such a bureau should possess a bibliographic card index, a collection of documents, a collection of chemical standards of raw materials and manufactures, a collection of samples, a list of research institutions, a list of manufacturers of products and plant, and a collection of commercial information and catalogues. The documentation would be made up of cards referring to both general, special and occasional literature. Such an office, useful in every way, could only reach complete utility in a "Chemistry House" in which were concentrated all the material and moral forces of associations of chemists and chemistry, thus corresponding to a programme under consideration by the Société de Chimie Industrielle.

March 12, was the centenary of the birth, in Königsberg, of Gustav Robert Kirchhoff, the pioneer investigator, with Bunsen, of spectrum analysis. Kirchhoff died in 1887.

CORRESPONDENCE

A GERMAN SCIENTIST'S OPINION

SIR,—In your Editorial of February 29, you profess yourself ignorant as to whether the majority of German scientists still approve the actions of the German Government before and during the World War.

Although I do not count among the leading German scientists I am enabled by a long and laborious life in the service of chemistry, which has brought me into contact with very many colleagues both at home and abroad, to inform you what is the current opinion amongst people of my circle concerning your way of thinking.

Before I go into details I should like to put the following question to you. What would you reply if a German, before entering into an exchange of scientific ideas with you, demanded of you publicly to condemn the attitude of the British Government during the Boer War or before the World War, an attitude which thwarted William II. in his striving after peace? I believe the reply would be that the matter need not be further discussed. We Germans, however, are well known to be always objective, and, as I cannot free myself from this national failing, I will therefore discuss your contention more closely.

You say that between the French and Germans there are deep misunderstandings and opine that the guilt of these differences falls on the Germans as they have invaded France twice within the last sixty years. Apart from anything else, the choice of the last sixty years has been made much to the detriment of Germany. If you will kindly contemplate a somewhat longer interval of time, entirely different grounds for these differences would come to the surface, grounds which are entirely to the discredit of the French. As regards the German invasions of France, the first took place as the reply to an insolent insult to our venerable monarch, who was to be challenged in order that his expected defeat would strengthen the tottering French throne. The enemy is recognised to have been treated most humanely in that campaign and, unfortunately, was allowed to escape with very mild peace conditions. The second invasion was rendered necessary because Germany had already palpable proofs of the fact that a number of jealous neighbours had banded together to carry out a stroke against her, by which she would be economically and politically weakened sufficiently to be unable to have a further voice as a serious competitor in the counsels of the world. That Germany first of all finished off the weakest of the accomplices in order to free the road to the most vindictive and dangerous adversary is, to my knowledge, a generally applied process when a harmless passer-by is attacked by robbers. Possibly the damaging of the foe went farther than wisdom counselled, but the damage was well-merited and the authors must be allowed extenuating circumstances as the purpose of the enemy plot was the economic ruin of Germany. These facts are, of course, represented by your Government and Press in a different light and it is a case of opinion *versus* opinion. Which of the two is the right one will be ascertained by impartial historic research. In the realms of science, however, it is not at all necessary to await this verdict, for a Peace Treaty has already been concluded between the belligerents. It is not a German custom to require of one of the combatants, after a treaty has been signed, that he should explicitly condemn his attitude before and during the struggle; nor is this generally the case in England. This demand can only be made of Germans. Why? Is the Peace Treaty not taken seriously in England either? It certainly is not taken seriously by the most dishonourable of our enemies, as he acts on the presumption that it is binding on Germany only. It is true that he signed it voluntarily but with the unmistakable intention of breaking it as soon as he felt strong enough. When this was the case, he broke the Treaty, invaded Germany, drove thousands of her inhabitants from their homes, imprisoned them and to this day carries out through his myrmidons the most revolting outrages against the property and liberty of the population of the occupied territories. No foreigner, able to judge objectively, who calls these facts to mind, will have the courage to demand of a German that he should disapprove of the actions of the German Government in the year 1914 in order to enjoy the privilege of being tolerated in an international assembly of scientists. Justice demands that, in the realms of science, politics should henceforth be mute! If the German scientists can conquer their feelings to the extent of forgetting the past and also the crying injustice which is still being meted out daily to their compatriots, it is a proof of self-abnegation which must suffice the scientists of all foreign nations as a basis of negotiations. We will then say to you, welcome!

I cannot hope that you will adopt this way of thinking. It is, however, the idea animating the vast majority of German scientists who hope therefore that no obscure German man of science may be found ready to accede to your wishes. Such admission as you require would surely be used to the detriment of the German nation, which would have to pay in the last resort for such a dishonourable and shameless attitude.—I am, Sir, etc.,

DR. P. FRITZSCHE

Leipzig

QUALIFICATION OF CHEMISTS

SIR,—I wish to give my support to the remarks of "An Unqualified Chemist" which appear in your current issue.

I was the pupil of a public analyst (a Fellow of the Institute), and a fee of 200 guineas was paid when my articles were signed. The laboratory in which I served my time was a regular "pupil shop." There were about half a dozen pupils altogether—the number varied—and although I cannot say that no time was devoted to teaching theory, the amount of time so spent did not exceed one hour per pupil per month! There was very little encouragement given to attend evening classes or to obtain theoretical knowledge otherwise. The only qualification required of a prospective pupil was the possession of

200 guineas ; there was no entrance examination whatsoever, and no consideration of one's previous educational record. At the end of the three years one had to find a job elsewhere—if possible.

Personally, I was lucky. About six months after the termination of my pupilship I obtained a job in a works, and now hold a responsible position.

By attending evening classes I have improved my theoretical knowledge and have gained the Associateship of the Manchester College of Technology in General Chemical Technology. Nevertheless, I am denied admission to the Institute.—I am, Sir, yours faithfully,

"Another Unqualified Chemist"

Sir,—I can assure "An Unqualified Chemist" that he is not alone in his amazement at the fearful and wonderful ways of the Institute of Chemistry. It is not only those who have no degrees who are victimised. I, personally, am a Master of Science, am just preparing to sit for the Doctor of Science (in Chemistry) and have been chief chemist to a firm of world-wide repute for seven and a half years. Presumably because I gained my degrees by spare-time study, without attending day classes in a university, the door is closed against me unless I pass their exam. This I will not do. On the other hand, I know men without degrees, but with friends in high places, who have been admitted without trouble. Their qualifications are no higher than mine. Can it be that kissing goes by favour ?

There is so much dissatisfaction with the Institute that one feels it should put its house in order before trying to dictate to the world who are and who are not chemists. "Who made thee a ruler and a judge over us ?"—Yours, etc.,

A Chemist

ROTATORY DISPERSION

Sir,—I followed with interest the discussion on rotatory dispersion at the last meeting of the Chemical Society, but was deterred from taking part in it by the closure of the discussion consequent on the lateness of the hour. If therefore you find the following remarks of sufficient interest I should be glad if you would publish them.

Dr. Pickard was very insistent that no rigid proof of the hypothesis that tartaric acid and its esters contain dynamic isomerides with rotatory powers of opposite sign and different dispersion had been brought forward. That must be admitted. Nevertheless the hypothesis accounts satisfactorily for :—

(a) the fact that the rotatory dispersion of these substances is undoubtedly complex and generally anomalous ;
(b) the manner in which the dispersion curves vary with change of temperature, concentration and solvent ;
(c) the fact that derivatives of high negative and high positive rotary power and (as far as can be determined) simple dispersion can be obtained.

It is granted that these facts form no rigid proof, and I would willingly abandon the hypothesis in favour of another embracing a still larger class of facts. Failing this, however, I see no reason for abandoning it until evidence can be found that it is incorrect.

With reference to Dr. Astbury's remarks I should like to protest against his contention that the rotatory dispersion of derivatives of tartaric acid has nothing to do with that of tartaric acid itself. No chemist would quarrel with Mr. Austin for seeking to increase our knowledge of tartaric acid by examining its derivatives, and no one who has studied rotatory dispersion can doubt that the ultimate cause of the complex dispersion of the esters and certain other derivatives of tartaric acid is the same as that of the acid itself.—I am, Sir, etc.,

E. E. Walker.

REVIEWS

Sir,—In the current issue of *Chemistry and Industry* there appears a review of a new book on clays and ceramic materials, which raises the question of reviews in general. I am not acquainted with this particular book, nor with its author, but think it unjust to the latter and unfair to your readers that a 700 page book should be dismissed with a few contemptuous lines. Those of us who have not ready access to an up-to-date scientific library are largely guided by your reviews in our purchase of new books, and we require information about the scope, arrangement and general treatment of the subject-matter, in addition to the reviewer's considered verdict on the book as a whole. When the reviewer disagrees with the author, surely the reasons for such disagreement should be given. If the book in question is as bad as your reviewer thinks it is, why mention it at all ? If he wants to save us from spending 55s. on it, he should tell us something about the book and give us some opportunity of judging for ourselves. Pontifical statements that a book is bad are valueless.

Another recent case which occurs to me, is the review in *Chemistry and Industry* (1923, 1013) of the new edition of Bloxam's "Chemistry." Here the reviewer is so intent on proving that the book has not been thoroughly revised, that he states dogmatically : ". . . It is noteworthy that no mention is made of permutit as a water softener." Had he taken the trouble to consult the index, he would have found this reference, both under "Permutites" and "Water softening."

Such cases, fortunately, are not frequent, but they do suggest that some reviewers should take their responsibilities more seriously.—I am, Sir, etc.,

N. K. Smith

CONTINUOUS CAUSTICISING AND CRESYLIC ACID

Sir,—The attention of Mr. Walmsley and myself has been drawn to the possible ambiguity of a statement which appears in the abstract of our paper "Notes on Continuous Causticising and Cresylic Acid," which appeared in *Chemistry & Industry* of March 7. The statement was that "There was

no advantage in obtaining the maximum causticity —a causticity of between 85 per cent. and 90 per cent. being ideal for the treatment of tar acids." That, of course, only applies to a continuous process where all factors aiding rapid settling of the precipitate produced have to be exploited and in which regenerated sodium carbonate is recausticised.—I am, Sir, etc.,

R. F. STEWART

Glasgow
March 19, 1924

HYDROGEN PEROXIDE AS A BLEACHING AGENT

SIR,—I have read Mr. Weber's letter in the last number of the *Journal*. I did not see the report of the discussion before publication. I know, of course, that hydrogen peroxide is used for bleaching gelatin. I intended to emphasise certain difficulties connected with its use. The extract given by Mr. Weber from Bennett's book indicates these also. They are: (1) Hydrogen peroxide is a poor bleaching agent in acid solutions. (2) If used in alkaline solutions there is some danger of hydrolysis of the gelatin. (3) Gelatin acts as an anti-catalyst, and at the temperature at which gelatin liquors are bleached, much of the peroxide remains undecomposed. (4) This residual peroxide, unless removed by means of a reducing agent, may cause a "bubbly" appearance in the dried cakes. I have such a sample before me as I write.—I am, Sir, etc.,

S. R. TROTMAN

1, Regent Street, Nottingham

PERSONAL AND OTHER ITEMS

Sir William M. Bayliss, F.R.S., Professor of Physiology in University College, London, has been elected by the Belgian Academy of Medicine a corresponding member.

Prof. H. von Halban has resigned his post as Conservator of the Chemical Institute of the University of Würzburg.

The Nichols Medal for 1924 was presented to Dr. C. A. Kraus, of Brown University, at the March meeting of the New York section of the American Chemical Society.

The Iron and Steel Institute has awarded the Bessemer gold medal for 1924 to Prof. A. Sauveur, professor of metallurgy and metallography at Harvard University.

Helium in South Dakota.

It is announced that drilling in S. Dakota has revealed the presence of a high-pressure natural gas well which has the largest content of helium yet recorded.

Explosion at Oppau.

The Times reports the explosion of a gas generator at the Badische Anilin und Soda works at Oppau. Considerable damage is reported to have been caused and it is thought that parts of the works will have to close down for three months.

FRANCE

Coal Output, 1923

The French production of coal in 1923 increased by 6,600,000 metric tons, to 38,576,815 t., a gain of roughly 20 per cent., due largely to the mines in the Nord and Pas de Calais districts, where reconstruction made great progress. In these districts alone the gain in production was nearly 5½ million t., or 35·4 per cent. Still better results are recorded for coke. Excluding coke ovens belonging to metallurgical works, the production of coke at the mines has increased from 1,030,755 t. in 1922 to 1,985,735 t. in 1923, a gain of nearly 95 per cent., this gain being largely due to the mines of the Nord district. A similar increase is shown in the output of briquettes, viz., 147·3 per cent. to 3,056,376 t.

Imports in 1923 comprised 26,269,865 t. of coal and lignite (17,954,597 t. from Great Britain), compared with 22,384,126 t. in 1922 (12,098,927 t. from Great Britain); coke, 3,628,398 t. in 1923, (384,101 t. from Great Britain), against 5,140,183 t. in 1922; briquettes, 776,267 t. Exports were, coal and lignite, 2,364,172 t.; coke, 496,398 t. and briquettes, 238,116 t. Supplies of coke are approaching those of 1913, and the new plant now under construction (*cf. Chem. & Ind.* 1923, p. 794), will bring about still further improvement.

CANADA

Water Power

Since 1900 when the total installed horse power was some 150,000, water power development in Canada has been very rapid, and to-day the Dominion possesses nearly 3,000,000 operating h.p. and some 21,000 miles of transmission and distributing system. The total value of water power production for present installation is estimated at over $83,000,000 per year. Out of the 3,000,000 operating h.p., no less than 900,000 h.p. is in the Province of Quebec, where there is an available total of 15,000,000 h.p.

AUSTRALIA

Radium mining

The Radium and Rare Earths Treatment Co., Melbourne, is working some radium-bearing properties at Mt. Painter, in South Australia, where a shaft has been sunk and some exploratory work carried out. The chief radio-active minerals on the property are torbernite (hydrated phosphate of uranium and copper) and autinite (hydrated phosphate of uranium and calcium). Another property is situated at Olary, near Broken Hill. Mr. S. Daddow, of London, has been appointed chemist to the company.—(*Chem. Eng. and Min. Rev., Dec.* 5, 1923.)

UNITED STATES

Factory Explosion

The daily Press reports that an explosion, "presumably of TNT," occurred on March 1 in the works of the Ammonite Co. at Nixon, near New Brunswick, causing many deaths and casualties. The Ammonite Co. was manufacturing a fertiliser from the materials contained in TNT shells after the TNT had been extracted at the arsenal, and it is supposed that some TNT left by error in the shells caused the explosion.

BRITISH INDIA

Final Memorandum of the Groundnut Crop of 1923-24

From information based on reports received from the three provinces of Madras, Burma and Bombay, which comprise 99 per cent. of the entire groundnut area of British India, the total yield is estimated at 1,078,000 tons of nuts in shell, as against 1,236,000 tons last year, or a decrease of 13 per cent. The total area under the crop is 2,731,000 acres, compared with 2,633,000 acres in 1922-23. The conditions of the weather on the whole have been unfavourable. The quantities exported by sea to foreign countries during the nine months (April to December) 1922-23 and 1923-24 have been 159,200 tons and 158,500 tons respectively.—(*Ind. Tr. J., Feb.* 21, 1924.)

GENERAL

Patents in Japan

A translation of all the Ordinances and Notifications published in Japan since the earthquake and relating to rights in industrial property has now been received, and may be consulted in the Public Library of the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. 2.

Notes from Italy

The Sugar Crop.—The production of beet sugar during the campaign 1923-24 in Italy by 39 factories was 3,114,500 quintals (from 28 million q. of beets grown on 93,000 hectares), compared with 2,616,073 q. (23·9 mill. q. of beets grown on 85,000 hectares) in 1922-23. Imports of sugar during 1923 totalled 314,626 quintals.—(*G. Chim. Ind. ed. App., Jan.,* 1924.)

The National Italian Congress of Industrial Chemistry will be held in Milan from April 12 to 17, when special attention will be paid to fertilisers, fuels and chemistry in the national defence. As the Sample Fair will be held at the same time, an exhibit will be provided to show the scope and quality of chemical production in Italy.

The Photographic Exhibition

This year the Photographic Exhibition has been held in conjunction with the Ideal Home Exhibition, so that visitors were more numerous than ever, although some prominent makers were not represented. Once again Messrs. Johnson, Matthey and Co., Ltd., delight the eye with their beautiful exhibit of crystals and silver nitrate, potassium chloroplatinite and gold chloride, and Messrs. Johnson and Sons show, in addition to various photographic chemicals, the various stages in the manufacture of the "Scales" brand of hydroquinone and metol. Messrs. David Allan demonstrate a variety of appliances designed to aid the photographer, many being suitable for use in laboratories where occasional photographs have to be taken at short notice. Of great interest, as showing the quality of British products, was the exhibit by Messrs. Wellington and Ward of prints from negatives on "Anti-Screen" plates which were developed in Central Africa at over 100° F., a severe test of quality. The same firm has introduced a new panchromatic plate, the "Spect[illegible] attract all interested in ortho-chromatic photography. Messrs. Ilford, Ltd., exhibited a fine series of colour filters and illustrated the various steps in the making of a dry plate. Many well known makers of photographic products, papers films and plates were represented, and the high quality of the specimen prints exhibited provided convincing testimony to the excellence required to keep in the front rank of this particularly English industry.

REVIEW

Quantitative Chemical Analysis. *By* Prof. Frank Clowes, D.Sc., and Prof. J. Bernard Coleman, A.R.C.Sc. *Twelfth Edition. Pp.* vii + 576. *London: J. and A. Churchill,* 1924. *Price* 18*s*.

The twelfth edition of this well-known book by the late Prof. Frank Clowes and Prof. J. B. Coleman has just been issued. First published in 1891 as a book of instruction in quantitative analysis, its range has, in the course of time, been extended so much, as to render it also a useful book of reference on general analysis for those engaged in analytical and consulting practice.

The arrangement of the matter conforms to the primary purpose of the book. After an introductory part covering 72 pages, which deals with the preliminary and general operations employed in analysis, comes a description of the more important gravimetric determinations of single substances. This is followed by a similar section dealing with volumetric analysis. After this comes Part IV, which covers an immense range of applications. The analyses of alloys, of ores, of silicates, of iron and steel, of water, of food, of soap and oils, fat and waxes, are dealt with. Part V is devoted to the ultimate analysis of organic compounds and the determination of molecular weights. Part VI deals with methods of gas-analysis by means of the Hempel apparatus and the Lunge nitrometer. The determination of vapour density by the Victor Meyer and the Dumas method is also described in this section. The remaining parts contain typical results of analyses, tables of useful constants, and details regarding the materials used in the analytical laboratory such as distilled water, compressed gases, analytical reagents, etc.

The book has deservedly achieved a high degree of popularity on account of its detailed and trustworthy directions. Only well-tried and established methods are given. As a result, a student who has worked conscientiously through only a fraction of the contents of this book will have attained confidence in his own work, and the large number of practical applications given to the teacher to choose from, render it easy to maintain and stimulate the student's interest. The qualities which render the book valuable to the student will also commend it to the practitioner. For work of a more special nature references are given to suitable treatises. The reviewer has no doubt that the book will maintain its popularity among the chemical profession.

Henry J. S. Sand

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Safeguarding of Industries Act

Mr. Graham stated in reply to Sir F. Wise that the revenue received under Part I and Part II of the Safeguarding of Industries Act during the period from April 1, 1923, to February 29, 1924, amounted to £357,000 and £230,000 respectively.—(Mar. 12.)

Fire Precautions

Answering Mr. Gray, Mr. Henderson said that the recommendations dealing with fire precautions in factories and workshops he hoped to incorporate in the Bill which is now under consideration, and the Report of the Royal Commission on Fire Brigades and Fire Protection would no doubt afford a useful basis for legislation on other topics, as opportunity offered. With regard to the recommendations made by the Commission on the subject of fire brigade organisation, he could not say when legislation would be possible.—(Mar. 13.)

Safeguarding of Industries Act

In reply to Sir F. Wise, Mr. Graham said that the net amount of revenue received under Part II of the Safeguarding of Industries Act on mantles for incandescent lighting and component parts thereof, during the months from April, 1923 to February, 1924 inclusive, was £35,867.—(Mar. 13.)

Safeguarding of Industries Act

Mr. Webb, in reply to Mr. Lamb, said he was aware that serious unemployment was being created in the pottery trade (china) because German and Czechoslovakian ware was being imported at prices below the British cost of production, but he did not feel that any advantage would be gained in forming a committee to report on the position.—(Mar. 18).

Glass and Hollow-ware

Answering Major Burnie, Mr. Webb said he had received from members of the glassware trade and the hollow-ware trade, applications for the Depreciated Currency Order of October 1922, issued under Part II, of the Safeguarding of Industries Act, to be reconsidered by a committee set up by the Board of Trade in accordance with Section 9 of the Act, on the ground that German exports to this country were no longer assisted by a depreciated currency. He had invited the applicants to furnish certain information, on receipt of which the applications would be carefully considered.—(Mar. 18.)

Poison Gas

Replying to Mr. Broad, Mr. Walsh said that the expenditure in the current financial year on poison-gas experiments was about £80,000, and a similar sum had been provided for 1924-25. The animals experimented upon were cats, guineapigs, goats, mice, monkeys, rabbits and rats. The total number used from April 1, 1923, to the present date was 689, out of which 618 animals have been killed or destroyed. The Government was a signatory to the Washington Resolution of [illegible], which condemned the use in war of asphyxiating and poisonous gas, but this Resolution had not yet been ratified by all the signatory powers.—(Mar. [illegible]).

Dyestuffs

Answering Mr. Turner, Mr. Webb said that the negotiations between the British Dyestuffs Corporation and the Interessen-Gemeinschaft were still proceeding and no draft agreement had yet been submitted to the Board of Trade.—(Mar. 18).

COMPANY NEWS

UNITED ALKALI CO., LTD.

At the annual meeting the chairman said that, generally speaking, the year had been one of steady progress. A feature of outstanding interest was the centenary of the alkali industry in this country, at which some 1300 guests, including scientists, public men and consumers were entertained and shown some of the operations of the company. The effect was being followed up by a striking display at the British Empire Exhibition, where, under the auspices of the Association of British Chemical Manufacturers, was being prepared a survey of British chemistry, from the simplest practical processes to the most advanced theoretical developments, which was expected to be unique in the history of exhibitions. Referring to the company's interests in Spain, the chairman said that much attention had been given to the close co-ordination of the mines and their consuming works. The results obtained entirely justified the policy adopted, and very large quantities of pyrites were available at a cost much below the price at which this raw material for the production of sulphuric acid could be bought from any other source.

An efficient research organisation had always been well maintained, and with the company's large interests in the development of the organic chemical business in this country it had been necessary to increase these research facilities still further.

In conclusion the report and accounts were adopted (*cf. Chem. & Ind.*, p. 235, 1924).

BRITISH PORTLAND CEMENT MANUFACTURERS, LTD.

The final dividend on the ordinary shares is to be 5 per cent., making 10 per cent. for 1923. The carry forward is £187,751. The same dividend was paid in 1922, when the carry forward was £188,144.

BRITISH GLASS INDUSTRIES, LTD.

At the annual meeting, the chairman, Sir W. Sinclair, reviewed the position of the company and its associated companies, and reported progress in the scheme of reorganisation. To reorganise the company it was proposed to reduce the capital from £5,000,000 to £2,255,218, and to increase the reduced capital to £5,000,000 by the issue of 2,409,709 new £1 shares and 1,340,291 new 5s. shares. The working for the 21 months ended December 31, 1923, resulted in a net loss of £32,412, but he (the chairman) believed the corner had been turned; all the associated companies were making profits and the reorganisation would have a favourable influence. The report and accounts were adopted.

REPORTS

First Experimental Report to the Atmospheric Corrosion Research Committee of the British Non-Ferrous Metals Research Association. *By* W. H. J. Vernon, B.Sc. *Pp.* 62 (*Presented to the Faraday Society, Dec.* 17, 1923.)

Mr. Vernon's report is a record of a patient and conscientious study of the alteration which occurs to various metals when exposed to different atmospheric conditions over periods ranging up to twelve months. The work was carried out at the Royal School of Mines, South Kensington; Mr. Vernon expresses his appreciation of the advice and encouragement accorded him by Prof. H. C. H. Carpenter, F.R.S., and the staff. The full measure of the valuable and detailed information included in the report will only be gained by reference to the original. All that can be attempted in the present brief survey is to call attention to the most important results which have emerged from Mr. Vernon's work.

The research concerns "tarnishing" or "surrosion," rather than "corrosion" in the ordinary sense, since the layer which was produced on the metallic specimens exposed in the tests generally clung closely to the unattacked metal. In fact, in the quantitative work, the magnitude of the alteration was expressed not by the *loss* of weight, but by the *gain* in weight. The discoloration of the surface as a result of exposure was also studied, and the loss of "reflectitivity"—measured by Guild's method on a Lummer-Brodhun photometer—was employed as an alternative means of following the tarnishing process.

The larger portion of the report is devoted to the description of "*Field Tests*," in which metal plates measuring 10 cm. square (either with polished or matte (emeried) surfaces) were exposed to four different types of atmosphere. These were :—

(1) Exposure in a *basement-room* at South Kensington, which was heated continuously so as to keep the temperature above the dew-point; thus the air was always *unsaturated* with water vapour.

(2) Exposure in a *tank-room*, in which the moisture content from time to time *reached the saturation value*.

(3) Exposure in an ordinary domestic *kitchen* at Wimbledon, in which gas was used for cooking and lighting.

(4) Exposure *out of doors* on the roof of the Royal School of Mines at South Kensington.

The metals and alloys studied included copper, zinc, brass, nickel, nickel silver, monel metal, cupronickel, fine silver, standard silver, "special standard" silver (containing 1·75 per cent. cadmium) and iron. The behaviour of iron differed fundamentally from that of copper in that the iron rusted in isolated spots and remained bright elsewhere, whilst the copper soon became tarnished over the whole surface. The tarnishing of the copper specimens kept in the basement-room, however, usually commenced at the edge of the plates and extended inwards, a sequence of beautiful colours being observed. In the kitchen merely a gradual darkening of the copper occurred. The copper specimens exposed out of doors also darkened considerably, and over certain areas a blue deposit (containing sulphate) and a green deposit (containing presumably basic carbonate) appeared. The nickel specimens when exposed in the "kitchen" were found to be susceptible to the change known as "fogging"; in the early stages of fogging, the film produced was capable of being removed by washing with alcohol and rubbing with cotton-wool. Fogging was also noticed on some of the brass plates under all the "indoor" conditions of exposure; but here it was impossible to remove the film with alcohol. As regards the silver alloys, it is interesting to note that, whilst bright plates of "special standard" silver lost their reflecting power much more slowly in the kitchen atmosphere than did bright plates of ordinary "standard" and "fine" silver, there was little to choose between the three varieties when rough (emeried) surfaces were compared.

Particularly interesting are the results of the gravimetric method of following the progress of the attack. Curves showing the relation between weight increment (W) and time (t) have been plotted in many cases. Three types of curves may be distinguished :—

(1) Those in which the rate of increase *falls off* with the time, as the surface-film becomes thicker and obstructs the access of the tarnishing agent to the unchanged metal below. In the case of copper exposed in the warm basement-room, the curve is a parabola. It is significant that the same relation ($W^2=kt$) which was found by Pilling and Bedworth for the high-temperature oxidation of copper holds good for the tarnishing of copper in damp air at low temperatures.

(2) Those in which the rate of increase *does not alter* with the time. In the case of zinc exposed in the basement-room, the curve is a straight line, indicating that the corrosion product had no protective action on the unchanged metal below.

(3) Those in which the rate of attack *increases* with the time. The iron specimens kept in the tank-room rusted at a rate which increased as the rust accumulated.

The last seven pages of the report are devoted to the description of "*Laboratory Experiments*," mainly upon the tarnishing of copper by London air, which had been treated in different ways. Mr. Vernon thinks that, although hydrogen sulphide is certainly a powerful tarnishing agent when present, an appreciable amount of discoloration can occur even in air which contains very little hydrogen sulphide; he suggests that some other sulphur compound may have the power of causing the change, and describes an experiment in which tarnishing is produced artificially by means of a mixture of sulphur dioxide and benzene vapour. Whatever the tarnishing constituent in London air, experiments show that it is removed by filtration of the air through granulated silver, and even by washing with water.

The observation of U. R. Evans that the velocity of tarnishing of copper by hydrogen sulphide is very greatly reduced if the gas is dried is confirmed. But Mr. Vernon describes an experiment to show that not only water, but also benzene, has the power of accelerating the action of hydrogen sulphide on

the metal; he concludes that the tarnishing of copper is not an electrochemical process.

It is understood that these laboratory researches are being continued, and the publication of fresh results will be awaited with interest by all who have studied the present report. U. R. E.

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN VENEZUELA, SEPTEMBER, 1923. *By* T. J. MORRIS, *Chargé d'Affaires, Caracas. Department of Overseas Trade.* *Pp.* 31. *H.M. Stationery Office*, 1923. *Price* 1s.

Trade in Venezuela for the last twelve months has been comparatively good. The only difficulties imposed by the war were high freights and curtailment of markets. With these removed the country has made steady progress and seems likely to continue to do so (*cf. Chem. and Ind.*, 1923, 17). The greater part of the population is engaged in cattle raising, and the production of such agricultural commodities as coffee, cocoa, sugar, cotton, tobacco, and maize; balata, rubber, Tonka beans, timber, and other tropical forest products are also obtained. Coal is found in parts. The petroleum industry is now attracting great attention, and the most promising fields are in British hands; 334,923 tons was exported in 1922, against 218,146 t. in 1921, and with better transport facilities no doubt the industry would gain fresh impetus.

In 1921 imports were valued at £4,090,294, and exports at £5,719,909; in the first six months of 1922 they were £1,885,682 and £3,431,385, respectively. The United Kingdom and Trinidad supply about one-quarter of the imports, the United States about one half. British firms seeking business in Venezuela are in a good position for there is marked preference for their goods, owing to the cordial relations of the country with Britain. The principal distributing towns are Caracas, the capital of the country, for the comparatively wealthy centre and northern zone, Ciudad Bolivar for the hinterland and the south, a district of poor and primitive conditions, and Maracaibo for the petroleum areas and Andean regions; importers are recommended to work through all three centres together.

The principal imports are textiles, machinery, crockery, drugs, chemicals, perfumery, automobiles and foodstuffs. In drugs and chemicals British firms are not adequately represented, the United States, Germany and France holding the market. Among items of import in 1922 (first six months) were coal, 8008 t.; cement, 4215 t.; drugs, 257 t.; perfumes, soaps, and toilet preparations, 59 t.; tanned skins, 42 t.

Several manufactures hav[illegible]en started recently in the country, for producing [illegible] comparatively small scale cotton textiles, sole [illegible]her, soap, candles, cement, paper, and glass. [illegible] country has vast potential wealth in its mine[illegible]esources, which are, however, almost untouched [illegible]ng largely to shortage of labour, the population [illegible]e country being very sparse.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations; 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¼d. per lb.
Potass. Chlorate	3d.—3¼d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In
Sod. Bisulphite Powder 60/62%	Prices reduced to £18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis ..	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide ..	Expected to advance in sympathy with the crude metal.
Golden	5¼d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide ..	4s. per lb.
Carbon Bisulphide ..	£24—£26 10s. per ton according to quantity

Carbon Black .. .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.

Carbon Tetrachloride .. £56 per ton, drums free.

Chromium Oxide .. .. 1s. 3d. per lb.

Indiarubber Substitutes, White and Dark } 5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.

Lamp Black .. .. 40s. per cwt., barrels free.

Lead Hyposulphite .. .. 7½d. per lb.

Lithopone .. .. £22 10s. per ton.

Mineral Rubber "Rubpron" .. .. £15 10s. per ton f.o.r. London.

Sulphur .. .. £10—£12 per ton, according to quality.

Thiocarbanilide .. .. 2s. 9d. per lb.

Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.

Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade, but these are the only products in this section which show any activity.

Acetate of Lime—

Brown .. .. .. £14 10s. per ton d/d. Demand active.

Grey .. .. .. £21 per ton.

Liquor .. .. .. 9d. per gall. 32° Tw.

Charcoal .. .. .. £7 5s.—£9 10s. per ton, according to grade and locality. Market steady.

Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. " " 24° Tw.

Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.

Wood Creosote .. .. 2s. 7d. per gall. Unrefined.

Wood Naphtha—

Miscible .. .. 5s. per gall. 60% O.P. Dull market.

Solvent .. .. 5s. per gall. 40% O.P. Dull market.

Wood Tar .. .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.

Brown Sugar of Lead .. £47 per ton. Demand active.

TAR PRODUCTS

Acid Carbolic—

Crystals .. .. 7½d.—8d. per lb. Better demand, and firmer market. London prices reported up to 9d.

Crude 60's .. .. 2s.—2s. 3d. per gall. Market stronger; better demand; limited supplies.

Acid Cresylic, 97/99 .. 1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.

Pale 95% .. .. 1s. 10d.—2s. per gall. Steady demand.

Dark .. .. .. 1s. 8d.—1s. 11d. per gall. Steady business.

Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—

Strained .. .. 10d.—11d. per gall. Very quiet.

Unstrained .. .. 8½d.—9d. per gall.

Benzole—

Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.

Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.

Benzole, Pure .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.

Pure .. .. 1s. 8d.—1s. 11d. per gall.

Xylol coml. .. .. 2s. 3d. per gall.

Pure .. .. 3s. 3d. per gall.

Creosote—

Cresylic 20/24% .. 11d.—11¼d. per gall. Few inqui

Middle Oil .. .. } 8d.—9d. per gall. according

Heavy .. .. .. } grade and district. Mar

Standard Specification } easier.

Naphtha—

Crude .. .. 8d.—9d. per gall. } Better dema

Solvent 90/160 .. 1s. 2d.—1s. 4d. } Prices show

Solvent 90/190 .. 1s. 1d.—1s. 3d. } ward tenden

Naphthalene Crude—

Drained Creosote Salts £6—£8. Demand still good.

Whizzed or hot pressed £9 10s.—£12 per ton. Not mu inquiry.

Naphthalene—

Crystals and Flaked .. £18—£19 per ton.

Pitch, medium soft .. 65s.—70s. per ton. Better dema for prompt and forward deliver Prices hardening.

Pyridine—90/140 .. 17s.—17s. 6d. per gall. Mo demand at still higher price

Heavy .. 11s.—12s. Fewer inquiries.

INTERMEDIATES AND DYES

Business in dyestuffs has increased and reflects a improvement in the textile trade. Orders have been fo larger quantities than of late. Prices remain firm.

In the following list of Intermediates delivered price include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.

Acid H. .. .. .. 4s. 4½d. per lb. 100% basis d/d.

Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.

Acid Neville and Winther 5s. 10d. per lb. 100% basis d/d.

Acid Salicylic, tech. .. 1s. 4d. per lb. Steady demand.

Acid Sulphanilic .. .. 10½d. per lb. 100% basis d/d.

Aluminium Chloride, anhyd. .. .. 1s. per lb. d/d.

Aniline Oil .. .. 7½d.—8½d. per lb. naked at works.

Aniline Salts .. .. 7½d.—9d. per lb. naked at works.

Antimony Pentachloride 1s. per lb. d/d.

Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.

Benzyl Chloride 95% .. 1s. 3d. per lb.

p-Chlorphenol .. .. 4s. 3d. per lb. d/d.

p-Chloraniline .. .. 3s. per lb. 100% basis.

o-Cresol 19/31° C. .. 4¾d.—5¼d. per lb. Demand moderate.

m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.

p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate

Dichloraniline .. .. 3s. per lb.

Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.

p-Dichlorbenzol .. .. £75 per ton.

Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.

Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.

Dinitrobenzene .. .. 9d. per lb. naked at works.

Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.

Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.

66/68° C. 1s. 2d. per lb. naked at works.

Diphenylamine .. .. 3s. 3d. per lb. d/d.

Monochlorbenzol .. .. £63 per ton.

a Naphthol .. .. 2s. 5d. per lb. d/d.

β Naphthol .. .. 1s. 1d. per lb. d/d.

a-Naphthylamine .. 1s. 4½d. per lb. d/d.

β-Naphthylamine .. 4s. per lb. d/d.

m-Nitraniline .. .. 5s. 3d. per lb. d/d.

p-Nitraniline .. .. 2s. 4d. per lb. d/d.

Nitrobenzene .. .. 8½d.—9½d. per lb. naked at works.

o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. per lb. 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is dull and values generally lower.

Acid, Acetic 80% B.P.	£52 per ton.
Acid, Acetyl Salicylic	3s. 5d.—3s. 6d. per lb. Weaker tendency continues on a quiet market.
Acid, Benzoic	Commercial acid 2s. 6d. per lb. B.P. quality is being sold in small lots at 4s. 6d. lb.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	18s.—20s. per lb. Business normal.
Acid, Citric	1s. 6d. per lb., less 5% for ten lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	Market uncertain. Prices quoted from 2s. 3d. per lb. down to 1s. 10d. for ton lots. In good demand.
Acid, Tannic	3s. 0d. per lb. for B.P. quality
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 8d.—3s. per lb. Weaker. Offers at low prices are being made to stimulate the demand.
Amidopyrin	13s. 6d. per lb. Demand negligible
Ammon. Benzoate	3s. 6d.—3s. 9d. per lb. English make.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. 3d. per lb. Firmer.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9½d.—10d. English make Prices uncertain
Sodium	9½d.—10d. English make Prices uncertain
Ammonium	10½d.—11d. English make Prices uncertain
Calcium Lactate	2s. 3d. per lb. for best English make. This is cheaper than the Continental product of the same quality. Indifferent qualities are offered down to 1s. 9d. lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots.
Creosote Carbonate	6s. per lb. Little demand.
Guaiacol Carbonate	12s. 6d. per lb. for cwt. lots.
Hexamine	3s. 9d. per lb. for foreign makes. Weaker. Without much inquiry.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 3d. per lb. Foreign make.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 6d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	60s. per lb. Market firmer.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Very much firmer in view of the rise in the price of quicksilver.
Red oxide	4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	3s.—3s. 1d. „
White precip.	4s. 1d.—4s. 2d. „
Calomel	3s. 5d.—3s. 6d. „
Methyl Salicylate	2s. 7d.—2s. 9d. per lb. for carboys. Slightly easier.
Methyl Sulphonal	24s. per lb.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 4d.—1s. 8d. per lb. in free bottles and cases.
Phenacetin	6s. 6d. per lb. Dull.
Phenazone	7s. 6d. per lb. for cwt. lots. Spot prices much lower than forward offers. Firmer tendency.
Penolphthalein	7s. 3d.—7s. 6d. per lb. Firm.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. lb., 1-cwt. kegs included.
Potass. Permanganate—	
B.P. Crystal	8¾d.—9d. per lb. carriage paid. English make.
Commercial	8d.—8¼d per lb carriage paid. English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz tins. Steady market.
Resorcin	6s. 3d. per lb.
Salol	3s. 9d. per lb.
Silver proteinate	10s. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—	
Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	76s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.

Sod. Salicylate ..	..	A weak market with various prices quoted. Powder 2s. 7d.—2s. 10d. per lb. Crystal at 2s. 7d.—2s. 11d. per lb.
Sod. Sulphide—		
Pure recryst. ..	..	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous		£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal ..	..	18s. 6d. per lb.
Tartar Emetic ..	..	1s. 4d. per lb.
Thymol ..	..	13s. 6d.—15s. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.		
Aubepine ..	.. 13s. 6d.	,,	
Amyl Acetate ..	.. 3s.	,,	
Amyl Butyrate ..	.. 7s. 3d.	,,	
Amyl Salicylate ..	.. 3s. 6d.	,,	
Anethol (M.P. 21/22° C.)	4s.	,,	Advanced.
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d.	,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d.	,,	
Benzaldehyde free from Chlorine ..	.. 3s. 6d.	,,	
Benzyl Benzoate ..	.. 3s. 6d.	,,	Cheaper.
Cinnamic Aldehyde Natural ..	.. 16s. 6d.	,,	Cheaper.
Coumarin ..	.. 20s.	,,	
Citronellol ..	.. 16s.	,,	
Citral ..	.. 10s.	,,	
Ethyl Cinnamate ..	.. 15s.	,,	
Ethyl Phthalate ..	.. 3s. 9d.	,,	
Eugenol ..	.. 11s.	,,	Advanced.
Geraniol (Palmarosa)	.. 35s.	,,	
Geraniol ..	.. 10s.—17s. 6d. per lb		
Heliotropine ..	.. 8s. 3d. per lb.		
Iso Eugenol ..	.. 15s. 9d.	,,	
Linalol ex Bois de Rose ..	21s. 6d.	,,	
Linalyl Acetate ..	.. 21s. 6d.	,,	
Methyl Anthranilate	.. 9s. 6d.	,,	
Methyl Benzoate ..	.. 6s.	,,	
Musk Ambrette ..	.. 52s. 6d.	,,	
Musk Xylol ..	.. 19s.	,,	
Nerolin ..	.. 4s.	,,	
Phenyl Ethyl Acetate	.. 12s. 6d.	,,	
Phenyl Ethyl Alcohol	.. 16s.	,,	
Rhodinol ..	.. 57s. 6d.	,,	
Safrol ..	.. 1s. 10d.	,,	
Terpineol ..	.. 2s. 9d.	,,	
Vanillin ..	.. 25s. 3d.—26s. 6d. per lb.		

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. ..	.. 15s. per lb.
Anise Oil ..	.. 2s. 6d. per lb. Firmer market forward.
Bergamot oil ..	.. 17s. per lb. Still advancing.
Bourbon Geranium Oil ..	32s. ,, ,, ,,
Camphor Oil ..	.. 75s. per cwt.
Cananga Oil, Java	.. 10s. per lb.
Cinnamon Oil, Leaf	.. 6½d. per oz.
Cassia Oil, 80/85%	.. 9s. 3d. per lb.
Citronella Oil—	
Java 85/90% ..	.. 5s. 3d. ,,
Ceylon ..	.. 3s. 9d. ,,
Clove Oil ..	.. 8s. 4½d. ,,
Eucalyptus Oil 70/75%	.. 2s. 3d. per lb.
Lavender Oil—	
French 38/40% Esters	24s. 6d. per lb.
Lemon Oil ..	.. 3s. 4d. ,, dearer.
Lemongrass Oil	.. 2¾d. per oz.
Orange Oil, Sweet	.. 12s. 6d. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 30s. per oz.
Anatolian ..	.. 24s. 6d. per oz.
Palma Rosa Oil ..	.. 18s. 6d. per lb. Very short supply.
Peppermint Oil—	
English ..	.. 70s. per lb.
Wayne County	.. 19s. 3d. per lb. Again advanced.
Japanese ..	.. 18s. 3d. per lb., but very little being offered.
Petitgrain Oil ..	.. 9s. 6d. per lb.
Sandal Wood Oil—	
Mysore ..	.. 25s. per lb.
Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY

Applications

Akt.-Ges. für Chemische Produkte vorm. H. Scheidemandel, Askenasy, and Sakom. Manufacture of colloidal substances in grains etc. 5173. Feb. 28.

Bibby. 5668. *See* 11.

British Thomson-Houston Co., Ltd. Processes for making emulsions. 4819. Feb. 25. (U.S., 27.2.23.)

Carretero. Drying apparatus. 5354. Mar. 1. (Sp., 7.6.23.)

Compagnie Générale du Basalte C.G.B. Tilting melting-furnace. 4944. Feb. 26. (Fr., 29.6.23.)

Grauss. Centrifugal drying-machines etc. 5552. Mar. 4. (Fr., 8.3.23.)

Hansen. Method of producing porous substances. 5997. Mar. 8. (Denmark, 9.2.24.)

Hertenbein. Apparatus for extraction of solid matters in suspension in liquids. 5971. Mar. 8. (Fr., 12.3.23.)

Hood. Mixing-machine. 5692. Mar. 5.

International Combustion Engineering Corporation. Pulverisers. 4833. Feb. 25. (U.S. 15.3.23.)

Lengersdorff. Furnaces etc. 4924. Feb. 26. (Ger., 26.2.23.)

Millar. Crystallisation and drying of soluble substances. 5219. Feb. 29.

Nyrop. Treatment of liquids alone or in conjunction with gases or vapours. 4826. Feb. 25.

Pehrson and Pehrson. Rotary furnaces. 4798. Feb. 25.

Rigby. Rotary kilns. 5289. Mar. 1.

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Separation of gaseous mixtures. 4799. Feb. 25. (Fr., 10.3.23.)

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Purification of gases etc. 6017. Mar. 8. (Fr., 20.11.23.)

Cooke and Michel. Agitating and mixing device. 6067. Mar. 10.

Deutsche Ton- und Steinzeug-Werke A.-G. Grinding-mills. 6394. Mar. 12. (Ger., 3.12.23.)

Garstang. Furnaces. 6337. Mar. 12.

Haas. Drying-tunnel etc. 6184. Mar. 11.

Hanemann and Speichert. Vacuum furnaces. 6426. Mar. 12. (Ger., 15.3.23.)

Hutchins and Swinburne. Extraction of dust etc. from gases and liquids. 6259. Mar. 11.

Lloyd. Filtering liquids. 6527. Mar. 13.

Merle. Method of manufacturing solid products from liquid or plastic materials. 6524. Mar. 13.

Patterson, and Worthington-Simpson, Ltd. Evaporators. 6514. Mar. 13.

Sellars. Preparations for building furnaces etc. 6176. Mar. 11.

Soc. Anon. le Carbone. Process for rendering porous powder impermeable to liquids. 6623. Mar. 14. (Fr., 27.12.23.)

Wade (Silica Gel Corporation). Separating a gas from a mixture of gases. 6296. Mar. 11.

Complete Specifications Accepted

29,946 (1922) and 4554 (1923). Mackenzie, Silvester, and Outwin. Fractionating, distilling, or scrubbing column. (211,542.) Mar. 5.

32,160 (1922). Jung. Filtering apparatus. (197,910.) Mar. 5.

32,231 (1922). Schnetzer. Preventing formation of scale in steam-boilers, evaporators, economisers, etc. (211,588.) Mar. 5.

32,700 (1922). Pickford. Recovery of volatile liquids, solvents, etc. (211,599.) Mar. 5.

32,734 (1922). Cashman. Furnaces. (211,962.) Mar. 12.

32,753 (1922). Burn, Lancaster, and Langford. Mixing or washing viscous, plastic, or pulverulent substances. (211,965.) Mar. 12.

1570–1 (1923). Patrick. Manufacture of catalytic agents. (212,034–5.) Mar. 12.

3938 (1923). Silica Gel Corporation, and Patrick. Manufacture of gels. (212,065.) Mar. 12.

5111 (1923). Minimax Ges. Production of foam for fire-extinguishing. (204,007.) Mar. 12.

6316 (1923). Knight and Smith. Means for separating liquids of different specific gravities. (211,717.) Mar. 5.

6445 (1923). Appareils et Evaporateurs Kestner. Evaporating apparatus for concentrating acid liquids. (195,365.) Mar. 5.

13,502 (1923). Oderberger Chemische Werke Akt.-Ges. Production of colloidal solutions and reversible dried residues. (197,966.) Mar. 12.

19,609 (1923). Roeder. *See* V.

24,423 (1922) Ionides, and Ransome Machinery Co. (1920), Ltd. Mixing machines (212,163.) Mar. 19.

30,726 (1922). Naamlooze Vennootschap Algemeene Norit Maatschappij. Process for treating liquids. (188,667.) Mar. 19.

33,341 (1922). Gill. Furnaces, gas-producers, etc. (212,303.) Mar. 19.

735 and 734 (1923). Roucka. Indicating, measuring, or recording physical or chemical quantities or qualities at a distance. (191,729 and 191,730.) Mar. 19.

901 (1923). Elmore, and Chemical and Metallurgical Corporation, Ltd. Tanks and other objects with acid-resisting linings and coverings. (212,355.) Mar. 19.

4115 (1923). Roucka. Apparatus for indicating, measuring, or recording physical or chemical quantities or qualities. (193,398.) Mar. 19.

6982 (1923). Roucka. Apparatus for recording physical or chemical values. (194,717.) Mar. 19.

20,531 (1923). McIntyre, and Milne and Son, Ltd. Grinding, refining and mixing machines. (212,490.) Mar. 19.

II.—FUEL; GAS; DESTRUCTIVE DISTILLATION; MINERAL OILS; LIGHTING

Applications

Bibby. Filtration of gas etc. 5668. Mar. 8.

Donald. Drying peat etc. 5108. Feb. 28.

Fathers and L[illegible]h. Manufacture of fuel briquettes. 5819. Mar. 6.

General E[illegible] Ltd. Manufacture of incandescent bodies [illegible] etc. 5060. Feb. 27. (Ger., 29.8.23.)

Goffin. Manufacture of coal gas. 5970. Mar. 8.

Goskar. Manufacture of carbonised briquettes. 594 Mar. 8.

Goyan. Bituminous solution. 5756. Mar. 6.

Green. Water-gas plants. 4982. Feb. 27.

Heath. Manufacture of hydrocarbons of low boiling poin from hydrocarbons of high boiling point. 5049. Feb. 27.

Hinman. Artificial fuel. 4821. Feb. 25.

Jackson. 4900. *See* IX.

Koppers. Ovens for distilling fuel. 5449. Mar. 3 (Ger., 2.3.23.)

Mackenzie, Outwin, and Sylvester. Carbonising plant etc 5272. Feb. 29.

Minerals Separation, Ltd., and Wood. Treatment o finely divided coal. 5263. Feb. 29.

Morris. Gas-generating apparatus. 5306. Mar. 1.

Novák and Trebicky. Extraction of coal, peat, etc. 5790 Mar. 6.

Simon. Combustion of waste and residues. 5770. Mar. 6

Simon. Firings for readily-ignitable fuels. 5771. Mar. 6 (Ger., 10.3.23.)

Simon. Combustion of granular etc. fuels. 5772. Mar. 6 (Ger., 5.4.23.)

Smith. Heat treatment for fuels etc. 5103. Feb. 28

Thompson. Apparatus for drying and utilisation of peat 4845. Feb. 26.

Aktiebolaget Separator. Reclaiming oil from chips 6140. Mar. 10. (U.S., 23.8.23.)

British Thomson-Houston Co., Ltd. 6510. *See* XII.

Dunstan, Pitkethly, and Smith. Utilisation of gas. 6371. Mar. 12.

Forwood and Taplay. Treatment and production of hydrocarbons. 6705. Mar. 15.

Glasgow. Manufacture of water-gas. 6521. Mar. 13.

Rice. Smokeless fuel. 6223. Mar. 11.

Complete Specifications Accepted

33,113 (1922). Jorgonsen, Ronne, and Middelboe. *See* IX.

33,335 (1922). Du Boistesselin, Dubois, Tabb, Varnier, and Hertenbein. Agglomeration of powdered or finely crushed fuel by means of pitch. (197,639.) Mar. 19.

33,341 (1922). Gill. *See* I.

33,563 (1922). Lymn. Utilising caking fuel in gas-producers. (212,311.) Mar. 19.

23,087 (1923). Boyen. Purification of brown coal wax. (209,389.) Mar. 19.

26,805 (1922). Smallwood. *See* X.

29,068 (1922). Kirke. Water-gas plants. (211,537.) Mar. 5.

29,111 (1922) and 17,607 (1923). Lockwood. Treatment of coal or other mineral. (211,538.) Mar. 5.

31,686 (1922). Algemeene Norit Maatsch. Production of decolorising carbon. (189,148.) Mar. 5.

32,387 (1922). Koppers Co. Purification of gases. (190,131.) Mar. 12.

32,961 (1922). Marshall. *See* XII.

1787 (1923). V.L. Oil Processes, Ltd., and Lucas. Treatment of mineral oils. (211,664.) Mar. 5.

1922 (1923). Greene and Laucks. Carbonising coal. (211,667.) Mar. 5.

3190 (1923). Starkey. Low or medium temperature distillation of oil shale, bituminous coal, etc. (212,053.) Mar. 19

10,879 (1923). Travers and Clark. Manufacturers of gas from coal etc. (211,748.) Mar. 5.

27,677 (1923). Koppers Co. Purification of gases. (212,201. Mar. 12.

31,451 (1923). Algem. Norit Maatsch. Process of producing decolorising carbon. (208,555.) Mar. 5.

III.—TAR AND TAR PRODUCTS

Applications

Edwards. Production of phenolic compounds from co tar etc. 6352. Mar. 12.

[illegible]

solid hydrocarbons from tars. 6268. Mar. 11. (Ger., 11.9.23.)

Rütgerswerke Akt.-Ges. Decreosoting tar and tar oils. 6608. Mar. 14. (Ger., 24.3.23.)

IV.—DYESTUFFS AND INTERMEDIATES

Applications

Durand et Huguenin Soc. Anon. Production of fast dyes. 5365. Mar. 1. (Ger., 9.3.23.)

Durand u. Huguenin Akt.-Ges. Manufacture of mordant dyestuffs. 5441. Mar. 3.

Pereira. Manufacture of vat dyes. 4937. Feb. 26. (Austria, 2.3.23.)

Pereira. Manufacture of vat dyes. 4938. Feb. 26. (Austria, 7.4.23.)

Scottish Dyes, Ltd., Smith, and Thomas. Production and purification of colouring-matters. 5273. Feb. 29.

Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Manufacture of dyestuffs. 6241. Mar. 11.

Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Manufacture of dyes. 6507. Mar. 13.

Cie. Nationale de Mat. Colorantes et de Prod. Chim. Manufacture of black vat dyestuffs. 6632. Mar. 14. (Fr., 16.3.23.)

Ransford (Cassella und Co.). Manufacture of dyestuffs. 6506. Mar. 13.

Scottish Dyes, Ltd., and Thomas. Production of dyestuff intermediates. 6091. Mar. 10.

Scottish Dyes, Ltd., and Woodcock. Manufacture of anthraquinone derivatives. 6092. Mar. 10.

Complete Specifications Accepted

29,258 (1922). Burt, Boulton, and Haywood, Ltd., and Miles. Manufacture of indophenolic bodies. (211,541.) Mar. 5.

1223 (1923). Green, Saunders, Frank, and British Dyestuffs Corporation, Ltd. Manufacture of azo dyestuffs. (212,029.) Mar. 12.

1314 (1923). Green, Saunders, Frank, and British Dyestuffs Corporation, Ltd. Manufacture of azo dyestuffs. (212,030.) Mar. 12.

9708 (1923). Imray (Soc. of Chemical Industry in Basle). Manufacture of monoazo dyestuffs. (211,742.) Mar. 5.

10,584 (1923). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of vat colouring-matters. (212,145.) Mar. 12.

11,223 (1923). Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of azo dyestuffs. (211,752.) Mar. 5.

20,401 (1923). Durand u. Huguenin Akt.-Ges. *See* VI.

20,488 (1923). Durand u. Huguenin Akt.-Ges. *See* VI.

20,748 (1923). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of vat colouring matters. (211,802.) Mar. 5.

25,666 (1923). Pereira. *See* XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER

Applications

Bader, Eggert, and Wagner. Process for making artificial horn etc. from viscose. 5629. Mar. 5.

Cross, and Viscose Development Co. Manufacture of cellulose products. 5785. Mar. 6.

Granton. Method for de-inking printed paper. 5349. Mar. 1.

Havenith. Manufacture of artificial silk. 4777. Feb. 25.

Hinchley, and Stream-Line Filter Co. Recovery of detergents etc. used in cleaning fabrics. 5558. Mar. 4.

Newman. Paper. 4832. Feb. 25. (U.S., 2.11.23.)

Stocker. Treatment of artificial yarns wound on reels. 5512. Mar. 4.

Warren. Grinding wood pulp. 4896. Feb. 26.

A.-G. für Anilin-Fabr. Process of washing artificial silk. 6125. Mar. 10. (Ger., 3.12.23.)

Ingham. Treating paper. 6340. Mar. 12.

Marks (Naamlooze Vennootschaap Hollandsche Kunstzijde Industrie). Process for preparing artificial silk. 6100. Mar. 10.

... of separating animal and vegetable fibres. 6158. Mar. 10. (U.S., 24.4.23.)

Pott. Process of treating fibres etc. 6095. Mar. 10.

Walker. Waterproof material. 6532. Mar. 13.

Complete Specifications Accepted

4219 (1923). Hölken. Manufacture of artificial silk threads. (212,068.) Mar. 12.

4220 (1923). Hölken. Making artificial silk threads. (211,691.) Mar. 5.

7821 (1923). Dehn (United States Wool Co.). Wool product. (211,729.) Mar. 5.

9447 (1923). Olander and Moisio. Manufacture of paper. (211,740.) Mar. 5.

16,009 (1923). Carpenter Chemical Co. Methods of treating silk. (199,729.) Mar. 5.

19,609 (1923). Roeder. Manufacture of fabrics for filter etc. (201,919.) Mar. 5.

15,405 (1923). Leo. Paper manufacture. (212,471.) Mar. 19.

VI.—BLEACHING; DYEING; PRINTING; FINISHING

Applications

Baddiley, Browning, and British Dyestuffs Corporation. Dyeing acetyl cellulose. 5045. Feb. 27.

British Dyestuffs Corporation, and Sanderson. Dyeing acetyl silk. 6027. Mar. 8.

Courlander. Preparation for bleaching etc. fabrics. 4875. Feb. 26.

Farbenfabr. vorm. F. Bayer u. Co. Dyeing acidyl celluloses etc. 5690. Mar. 5. (Ger., 28.5.23.)

Farrar and Whitehead. Dyeing-machines. 5635 and 5636. Mar. 5.

Buchanan. Bleaching and dyeing kiers etc. 6576. Mar. 14.

Elson and Hermon. Dyeing yarns etc. 6258. Mar. 11.

Higgins, Kershaw, and Bleachers Assoc., Ltd. Production of effects on textiles. 6663. Mar. 15.

Ingham. Treating paper. 6340. Mar. 12.

Ogden. Decolorising or bleaching animal fibres. 6159. Mar. 10.

Complete Specifications Accepted

28,881 (1922). Plauson's (Parent Co.), Ltd. (Plauson). Dyeing. (211,912.) Mar. 12.

4863 (1923). Smethurst. Apparatus for bleaching etc. (212,084.) Mar. 12.

6738 (1923). British Dyestuffs Corporation, Ltd., Baddiley, and Shepherdson. Dyeing acetyl cellulose. (211,720.) Mar. 5.

10,664 (1923). Nuttall. Apparatus for dyeing and sizing yarns. (212,146.) Mar. 12.

18,442 (1923). Fuld and Hatch Knitting Co. Yarn-dyeing devices. (211,437.) Mar. 12.

20,401 (1923). Durand u. Huguenin Akt.-Ges. Manufacture of products for dyeing or printing textile fibres and other materials. (202,630.) Mar. 12.

20,488 (1923). Durand u. Huguenin Akt.-Ges. Manufacture of products for dyeing and printing textile fibres and other materials. (202,632.) Mar. 12.

18,235 (1923). Schoeller Gob. Apparatus for printing warps. (201,544.) Mar. 19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS

Applications

Jahl, and Michael & Co. Production of soluble barium salts. 4967. Feb. 27.

Johnson (Badische Anilin- u. Soda-Fabrik). Manufacture of alkali cyanide. 5345. Mar. 1.

Nathansohn. 5351. *See* X.

Nathansohn. 5352. *See* XIII.

Metal Traders, Ltd. Production of sulphuric acid. 6404. Mar. 12. (Ger., 7.4.23.)

Rhenania Verein Chemischer Fabriken Akt.-Ges. and Ster. Manufacture of barium hydroxide or strontium hydroxide. 6151. Mar. 10.

Smith, and Chemical and Metallurgical Corp. Treatment of lead chloride. 6734, 6735. Mar. 15.

Smith. Method of producing white commercial pure ammonium chloride. 6618. Mar. 14.

COMPLETE SPECIFICATIONS ACCEPTED

29,791 (1922). Nitrogen Corporation. Ammonia synthesis autoclave. (188,651.) Mar. 12.

2665 (1923). Howard and Alvord. Process of making metal sulphides. (212,045.) Mar. 12.

7813 (1923). Verein für Chemische und Metallurgische Produktion. Production of chemically-pure hydrochloric acid. (196,258.) Mar. 5.

18,911 (1923). Jackson (L'Air Liquide Soc. Anon.). Separation of the constituents of air and the production of argon. (212,185.) Mar. 12.

19,218 (1923). Henkel et Cie., and Weber. Treatment of ammonium chloride lyes in iron vessels. (211,791.) Mar. 5.

23,950 (1923). Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Process for the synthetic production of ammonia. (205,477.) Mar. 12.

6445 (1923). Appareils et Evaporateurs Kestner. *See* I.

14,954 (1923). Urfer. Synthetic production of ammonia. (199,032.) Mar. 19.

VIII.—GLASS; CERAMICS

APPLICATIONS

Michaelis. Manufacture of plate glass. 4897. Feb. 26. (Ger., 2.3.23.)

Oppermann. Melting glass. 4864. Feb. 26. (Belg., 23.5.23.)

Rowart. Drawing glass in sheet form. 5332. Mar. 1. (Belg., 5.3.23.)

Wade (Empire Machine Co.). Cooling and annealing sheet glass. 5548. Mar. 4.

Sellars. 6176. *See* I.

Soc. Anon. dite Progil. Cold enamelling on wood, metal, etc. 6122. Mar. 10. (Fr. 7.5.23.)

Young. Manufacture of porcelain etc. 6697. Mar. 15.

COMPLETE SPECIFICATIONS ACCEPTED

28,039 (1922). Grönqvist. Production of metallic coatings on refractory materials. (211,530.) Mar. 5.

30,764 (1922). Ruck and Lehane. Manufacture of refractory articles, such as retorts. (211,543.) Mar. 5.

12,621 (1923). Chem. Werke vorm. Auerges. Rendering enamel opaque. (197,933.) Mar. 5.

27,582 (1923). Danin. Production of refractory articles. (212,501.) Mar. 19.

IX.—BUILDING MATERIALS

APPLICATIONS

Cape Asbestos Co., Ltd., and Gow. Material for forming walls etc. 4905. Feb. 26.

Carpenter. Binder for binding an aggregate. 5600. Mar. 4.

Govan. 5756. *See* II.

Jackson (Warren). Manufacture of bituminous compositions. 4900. Feb. 26.

Lorenzetti, Marpillero, and Marzola. Manufacture of fibrous building material etc. 5867. Mar. 7.

Müller. Manufacture of bricks etc. for resisting X-rays etc. 5450. Mar. 3. (U.S., 8.9.23.)

Subox Akt.-Ges. Manufacture of building materials. 5581. Mar. 4. (Ger., 26.3.23.)

Ebner. Treatment of materials for manufacture of structural articles. 6588 [illegible] 14.

McHardy. Seasoning [illegible] 6196. Mar. 11.

COMPLETE SPECIFICATIONS ACCEPTED

33,113 (1922). Jo[illegible], Ronne, and Middelboe. Utilization of the combustion gases from rotary cement burning kilns. (212,298.) [illegible]r. 19.

33,340 (1922). Kitchen, Lefebure, and Powell Wood Process Syndicate, Ltd. Impregnation of timber. (212,301.) Mar. 19.

22,982 (1922). Andrews. Manufacture of Portland cement (211,517.) Mar. 5.

32,524 (1922) and 4269 (1923). Hodson. Manufacture of basic bricks etc. (211,944.) Mar. 12.

6192 (1923). Building Accessories and Flooring Co., Ltd., Goodwin, and Smith. Manufacture of coloured asphalt. (212,106.) Mar. 12.

21,143 (1923). Building Accessories and Flooring Co., Ltd., Goodwin, and Smith. Manufacture of asphalt. (212,188.) Mar. 12.

7250 (1923). Eriksson. Manufacture of a porous material from Portland cement. (212,419.) Mar. 19.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY

APPLICATIONS

Bagley. Blast etc. furnaces. 6625. Mar. 14.

Ellis (Bliss Co.). Process for working zinc. 6282. Mar. 11.

Ellis (Gamlon). Process for reducing ores. 6729. Mar. 15.

Ellis. Means for reducing ores. 6730. Mar. 15.

Morgan and Levin. Manufacture of wrought iron by piling. 6706. Mar. 15.

Rushen (Schreger). Utilisation of blast-furnace dust, burnt-out pyrites, etc. 6533. Mar. 13.

Smeeton, Smeeton-Wright Furnaces, Ltd. Protecting metals during cooling. 6548. Mar. 13.

Southern. Roasting and calcining ores etc. 6627. Mar. 14.

Cachemaille (Westinghouse Lamp Co.). Manufacture of thorium or bodies coated with thorium etc. 5037. Feb. 27.

Calver and Pocock. Treatment of metals etc. 5071. Feb. 27.

Compagnie Générale du Basalte C.G.B. 4944. *See* I.

Ferranti, Ltd., and Ferranti. Protection of metals. 5603. Mar. 4.

Ford. Manufacture of puddled iron. 5500. Mar. 4. (U.S., 9.4.23.) Mar. 4.

Hennes. Extracting metals from ores etc. 5697. Mar. 5.

Hutchins. Electrodeposition of metals. 5604. Mar. 4.

Millar. Desulphurisation and concentration of sulphide iron ores. 5908. Mar. 7.

Nathansohn. Separation of lead and zinc in roasted compound ores. 5174. Feb. 28.

Nathansohn. Process for obtaining products for metallurgical treatment from zinc chloride solutions. 5351. Mar. 1. (Ger., 9.7.23.)

Rogers. Silicon steel. 5194. Feb. 29.

Skappel. Splitting up ores etc. 4939. Feb. 26. (Nor., 26.2.23.)

Snead and Co. Heating and annealing metals. 4711. Feb. 25. (U.S., 15.3.23.)

Thierry. Welding aluminium. 6018. Mar. 8. (Fr., 20.6.23.)

COMPLETE SPECIFICATIONS ACCEPTED

32,682 (1922). Sunderland, and Sutcliffe. Bright annealing of wire etc. (212,291.) Mar. 19.

13,105 (1923). Fox. Treating the surface of bronze, brass, and like metals. (212,457.) Mar. 19.

26,805 (1922). Smallwood. Manufacture of ore or fuel briquettes etc. (211,529.) Mar. 5.

28,039 (1922). Grönqvist. *See* VIII.

28,919 (1922). Moxham. Treatment of silicious metal-bearing minerals. (211,536.) Mar. 5.

29,256–7 (1922) and 10,721 (1923). Leighton and Dendel. Manufacture of gold leaf. (211,539–40.) Mar. 5.

1321, 11,642–3 (1923). Petrie, and Petrie and McNaught, Ltd. Sherardising metals in wire or strip form. (212,0[illegible].) Mar. 12.

1356 (1923). Chief Consolidating Mining Co. Treatment of silicious ores. (201,879.) Mar. 5.

7252 (1923). Marks (American Manganese Steel Co.). Electric furnace melting of manganese steel scrap. (212,121.) Mar. 12.

8800 (1923). Jones. Smelting furnace. (212,136.) Mar. 12.

10,337 (1923). Harrison (Robertson Co.). Protecting metal articles. (211,746.) Mar. 5.

14,097 (1923). Potts (Electro-Metallurgical Co.). Zirconium steel and process of making same. (212,171.) Mar. 12.

15,061 (1923). Duparc. Alloy. (200,074.) Mar. 5.

17,831 (1923). Rossi. Powder for soldering aluminium. (211,780.) Mar. 5.

30,405 (1923). Rousseau. Machines for recovering precious metals. (212,208.) Mar. 12.

XI.—ELECTRO-CHEMISTRY

Applications

Brown. Storage batteries. 6332. Mar. 12.

Loke. Electric furnaces etc. 6134. Mar. 10.

Slater, Cunningham, and Fine Cotton Spinners' and Doublers' Assoc. Insulating material. 6724. Mar. 15.

Stimmel, Willis, and Consolidated Mining and Smelting Co. of Canada, Ltd. Acid-proof structures for electrolytic etc. operations. 6310. Mar. 12.

Brindley. Electric primary cells. 5246. Feb. 29.

Fuller's United Electric Works, Ltd., and Welch. Thermo-electric batteries. 4837. Feb. 26.

Hutchins. 5604. *See* X.

Müller and Strasser. Lead electrodes for accumulators. 5251. Feb. 29. (Swiss., 8.3.23.)

Price. Electric accumulators. 5343. Mar. 1.

Complete Specifications Accepted

31,895 (1922) and 20,868 (1923). Seal Co. (London), Ltd., Pattinson, Rose, and Jascourt. Inert galvanic cells. (211,571.) Mar. 5.

33,194 (1922). Quain. Ozone apparatus. (211,982.) Mar. 12.

6089 (1923). Mallett. Secondary batteries. (211,714.) Mar. 5.

7252 (1923). Marks. *See* X.

22,008 (1923). Metropolitan-Vickers Electrical Co., Ltd. (Westinghouse Electric and Manufacturing Co.). Electric furnaces. (212,190.) Mar. 12.

22,009 (1923). Metropolitan-Vickers Electrical Co., Ltd. (Westinghouse Electric and Manufacturing Co.). Electric furnaces. (212,191.) Mar. 12.

XII.—FATS; OILS; WAXES

Applications

Douglas-Pectin Corporation. Oil or fat emulsions. 4969. Feb. 27. (U.S., 4.9.23.)

Wilson. Detergent compositions etc. 5374. Mar. 3.

British Thomson-Houston Co., Ltd. Methods of protecting oils against oxidation. 6510. Mar. 13. (Fr., 13.3.23.)

Price. Treatment of oils. 6544. Mar. 13.

Complete Specifications Accepted

31,632 (1922). Dujardin. *See* XIX.

32,961 (1922). Marshall. Solutions of non-mineral oils with mineral oils. (211,978.) Mar. 12.

13,566 (1923). Lewis. Extraction of oils and fats from oil or fat bearing material. (212,461.) Mar. 19.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS

Applications

Jones. Manufacture of paint. 6704. Mar. 15.

Free, Shuck, and Maclean and Co. Manufacture of printing-inks. 6543. Mar. 13.

Nathansohn. Process for obtaining lead carbonate. 5352. Mar. 1. (Ger., 26.1.23.)

Complete Specifications Accepted

22,727 (1922). Gardner. Paints, enamels, japans, etc. (211,516.) Mar. 5.

6432 (1923). Smith (Indelible Coloration Corporation). Fusible staining-ink. (211,718.) Mar. 5.

XIV.—INDIA-RUBBER; GUTTA-PERCHA

Applications

Cohen. Manufacture of rubber from latex. 6619. Mar. 14. (Holl., 4.12.23.)

Broomfield and Russell. Manufacture of rubber compounds. 4892. Feb. 26.

Complete Specifications Accepted

22,645 (1922). Owen, and Rowe, White, and Co. Manufacture of articles from rubber. (211,515.) Mar. 5.

24,592 (1922). White (Goodrich and Co.). Manufacture of vulcanised articles. (211,524.) Mar. 5.

XV.—LEATHER; BONE; HORN; GLUE

Applications

Anderson. Manufacture of leather. 6066. Mar. 10.

Simmons, and British Xylonite Co., Ltd. 6714. *See* XIX.

Fitzgerald. Production of mouldable products from blood. 6082. Mar. 10.

Fitzgerald. Moulding solid objects obtained from blood etc. 6083. Mar. 10.

Bader, Eggert, and Wagner. 5629. *See* V.

British United Shoe Machinery Co. (United Shoe Machinery Corp.). Tanning hides etc. 5404. Mar. 3.

Miller. Treatment of leather. 5883. Mar. 7.

Walter. Manufacture and treatment of leather. 5789. Mar. 6.

Complete Specification Accepted

10,583 (1923). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of tanning materials. (212,144.) Mar. 12.

XVI.—SOILS; FERTILISERS

Application

Adelantado. Manufacture of phosphate fertiliser. 5710. Mar. 5.

Complete Specification Accepted

27,377 (1922). Thompson. *See* XIX.

XVII.—SUGARS; STARCHES; GUMS

Applications

Schlüter. Production of rice-starch. 5510. Mar. 4.

Kalhauge and Jorgensen. 6636. *See* XVIII.

Maxwell. Extraction of sugar. 6531. Mar. 13.

XVIII.—FERMENTATION INDUSTRIES

Application

Kalhauge and Jorgensen. Method of producing yeast from molasses etc. 6636. Mar. 14.

Complete Specification Accepted

29,576 (1923). Langemeyer. Manufacture of yeast. (207,546.) Mar. 19.

XIX.—FOODS; WATER PURIFICATION; SANITATION

Applications

Berczeller. Treatment of soy beans. 5327. Mar. 1.

Bolton and Mills. Apparatus for treatment of sewage etc. 4716. Feb. 25.

Bradley, Whynmper, and Peek, Frean and Co. Manufacture of chocolate. 5805. Mar. 6.

Croft and Letten. Manufacture of fish meal etc. 4985. Feb. 27.

Douglas-Pectin Corporation. Manufacture and use of a jellifying product. 4968. Feb. 27. (U.S., 23.4.23.)

Faitelowitz. Production of preserves of fruit etc. 4767. Feb. 25.

Magrath. Softening, sterilising, etc. water. 5550. Mar. 4.

Reynolds, and Joyes' Sanitary Compounds Co., Ltd. Purification of air. 6280. Mar. 11.

Simmons, and British Xylonite Co., Ltd. Manufacture of casein products. 6714. Mar. 15.

COMPLETE SPECIFICATIONS ACCEPTED

21,645 (1922). Sauer. Process for purifying liquids. (184,473.) Mar. 5.

26,617 (1922). Ward Baking Co. Production of food products. (186,634.) Mar. 19.

27,377 (1922). Thompson (Visser). De-watering activated sludge and producing a fertiliser therefrom. (212,220.) Mar. 19.

31,632 (1922). Dujardin. Manufacture of cattle-feeding cakes and oil. (211,923.) Mar. 12.

31,698 (1922). Elektro-Osmose A.-G. (Graf Schwerin Ges.), Ruppel, and Dietrich. Purification of water. (211,562.) Mar. 5.

12,587 (1923). Hilditch, Wheaton, and Crosfield and Sons, Ltd. Means for purifying or softening water by means of base-exchanging compounds. (212,453.) Mar. 19

XX.—ORGANIC PRODUCTS: MEDICINAL SUBSTANCES; ESSENTIAL OILS

APPLICATIONS

Agoleum Ges. Preparing stable colloidal solutions of silver. 6228. Mar. 11. (Austria, 14.3.23.)

Naugatuck Chemical Co. Treating styrol etc. 6251. Mar. 11. (U.S., 30.6.23.)

Sartig. Process of denicotinising tobacco. 5678. Mar. 5.

Soc. of Chemical Industry in Basle. Manufacture of 4-oxynaphthalene-1-arylketones. 5784. Mar. 8. (Swiss, 6.3.23.)

Wade (Karpen and Bros.). Manufacture of hexamethylenetetramine. 4932. Feb. 26.

COMPLETE SPECIFICATIONS ACCEPTED

32,520 (1922). Hirchberg. Compositions containing formaldehyde. (211,943.) Mar. 12.

14,502 (1923). Imray. (Soc. of Chemical Industry in Basle). Manufacture of solutions for medical injection. (211,771.) Mar. 5.

14,672 (1923). Bloxam. (Chem. Fabr. Griesheim-Elektron). Manufacture of acylacetyl compounds. (211,722.) Mar. 5.

21,181 (1923). Layraud. Manufacture of new salts of C.C-di-substituted barbituric acids. (202,660.) Mar. 12.

25,666 (1923). Pereira. Manufacture of 3.10-perylenequinone. (206,134.) Mar. 12.

26,749 (1923). Soc. des Etablissement Barbet. Apparatus for the production of formaldehyde by catalysis. (206,158.) Mar. 19.

28,997 (1923). Bloxam. (Chem. Fabr. Griesheim-Elektron). Manufacture of acylacetyl compounds. (211,814.) Mar. 5.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES

APPLICATIONS

Farmer. Colour photography and photographic printing. 5651. Mar. 5.

Sondermann, Woithe, and Ziehm. Manufacture of colloid layers containing chromate colloids sensitive to light. 6595. Mar. 14.

COMPLETE SPECIFICATIONS ACCEPTED

32,988 (1922). Clark. Production of photographic negatives. (212,294.) Mar. 19.

5000 (1923). [illegible]e. Light filters or screens. (212,390.) Mar. 19.

19,728 (1923). [illegible] Ges. für Anilin-fabrikation. Photographic films. (212[illegible]) Mar. 19.

XXII.—EXPLOSIVES; MATCHES

APPLICATIONS

Gurney. Matches. 4838. Feb. 26.

Rees. Matches etc. 5498. Mar. 4.

Schulz. Method of impregnating lucifer matches. 54 Mar. 3. (Ger., 6.3.23.)

XXIII.—ANALYSIS

APPLICATION

Newton and Newton. Apparatus for detecting noxic gases in the atmosphere. 5906. Mar. 7.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number:—*Argentina*: Centrifugal pumps (9319/F.L./E.C./A./2); *Australia*: Bootmaking materials (412/7/1/1/215); *Belgium*: Artificial silk (286); *Brazil*: Artificial silk yarns (305); *British India*: Steel (The Directors, Madras and Southern Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, London, S.W. 1); *Italy*: Linseed oil, varnishes (293), leathers (22275/F.W./M.C./2); *Norway*: Electrodes (298); *Poland*: Shellac, gum arabic (301); *United States*: Mustard-seed oil, rapeseed oil (22291/F.W./C.C./2).

Australia: Hardware (412/7/1/1/216); *Belgium*: Metals, chemicals (307); *British India*: Steel (East India Railway Co., 73-6, King William Street, London, E.C. 4, Ref. 3701/43/T.G./E.C.); *Ecuador*: Hardware (322); *Egypt*: Cast iron (12682/F.E/E.C/2); *France*: Sugar, (308); *Italy*: Leather (310); *Netherlands*: Artificial silk (313); Iron and steel tubes (314); *South Africa*: Fluid disinfectant (13,356/E.D./C.C./2); *United Kingdom*: Steel (Corporation of Trinity House, Trinity House, Tower Hill, London, E.C. 3); *United States*: Pharmaceutical goods, hardware (320).

Safeguarding of Industries Act

A complaint under Section 1 (5) of the above Act, that rongalite, sodium formaldehyde sulphoxylate and zinc formaldehyde sulphoxylate had been wrongly included by the Board of Trade in their lists of dutiable articles was recently submitted to arbitration under the above subsection, and the Referee has now awarded that they were properly so included and that the complaint has failed.

Patents in Jugoslavia

A copy of an Ordinance modifying the Regulations for applications for patents, etc., claiming priority under Article 4 of the Industrial Property Convention of 1911, may be consulted at the Patent Office Library, 25, Southampton Buildings, Chancery Lane, W.C. 2.

Trade Information

Mr. A. F. Bird, 22, Bedford Street, Strand, W.C. 2, has been appointed English agent for the sale of publications by the Chemical Catalog Co., Inc., of New York.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43, NEW SERIES. LONDON, FEBRUARY 1, 1924 No. 5

EDITORIAL

THE discussion on the organisation of the profession and science of chemistry held in the Hall of the Mechanical Engineers on the 23rd. of January, was extremely interesting. Mr. Woolcock opened the discussion in an admirable speech, handling the topic with shrewdness and tact. The remainder of the discussion was rather discursive, but some useful points were made in it. Reference has often been made to the solidity of the legal profession and many chemists consider that a rigid definition of the term "chemist" and a restriction of chemical employment to qualified chemists will solve a number of difficulties. A comparison of the two professions may be of interest in this connexion. There are probably many more lawyers in the country than chemists, but chemistry will probably in a very few years become of greater importance and the number of chemists using the word in a wide sense may greatly increase. At the moment the lawyers are comprised in two classes, barristers and solicitors, each clearly defined and closely protected. In addition to these the legal profession includes a few special varieties whose numbers are small, and a large number of assistants and clerks, highly skilled in their own intricate details, the majority of whom will never become either barristers or solicitors. There is no organisation or society which includes the whole profession. Every barrister belongs to one close corporation, every solicitor to another quite distinct one. The men who are destined to receive an income of only £250 or £300 or so a year probably do not belong to either. The solicitor acquires his position after an examination and an expensive and long apprenticeship. The barrister has to pass an examination which does not involve, we imagine, so much study as a chemical degree, but the passing of the examination does not suffice to teach the barrister his business. Only a small proportion of barristers actually practice their profession, and the difference between those who know their job and those who do not, is not tested by any examination. Degrees and other academic distinctions count for far less in the law than they do in science.

Instead of a score of chemical societies we find only the two great legal societies. The Society of Chemical Industry has a council with several committees, many local sections each with a committee and possibly a revision committee. Many of the members of the Society are also members of the Chemical Society, or the American Chemical Society, or the Institute, or the Dyers and Colourists, or some of the other organisations. These have their committees also and there must be several hundred members of the Society who are on some chemical committee and perhaps a hundred members who are on several committees. Many of our chemists spend an appreciable proportion of their time, perhaps a fifth, attending committee and other meetings. The average lawyer spends no time on such work; he cannot afford it. The necessary work is done by few individuals, but as there are only two societies the total volume of such work is very small. Then again the lawyers do not spend any time in reading papers to each other. They keep abreast of the progress of their work by reading their professional journals, which are few in number. No lawyer spends his evenings listening to papers on the consolidation of mortgages or the Rule in Shelley's Case. Some of our chemical friends spend several hours a week in attending various meetings in different parts of London and the Provinces, notwithstanding the fact that they can read all the most valuable papers a month later in a chemical publication. We are inclined to think that the value of these committee and other meetings is greatly over-estimated and that the time spent on them could be reduced to one-third without detriment to the science.

Again, there is much less specialisation in the law than in chemistry; the lawyers who specialise on divorce or on trade marks or on company law have no little society or journal of their own. They read the same journals as the other lawyers and never quite lose touch with the general progress of legal knowledge. The spare time of the lawyer is spent in legal committee and other meetings, but

outside his professional circle. You find lawyers on borough and town councils, acting as secretaries of golf-clubs, or debating in local political societies. How many chemists—we do not mean chemical manufacturers—are rural councillors, county councillors or privy councillors? How many are active members of the local Conservative, Liberal or Labour parties? How many are churchwardens or treasurers of local billiard clubs? Very few. How many are members of Parliament? The answer is none. How many write letters to the *Times*? The answer is two, and perhaps, their epistles are not always published. If chemists wish to make an impression on the public they should abandon the practice of reading papers to each other on some new method of detecting thiophene in beer or determining the hydrogen ion concentration of clay soils in Northamptonshire. This sort of information should be published. Every day you may read in the *Times* a few columns of legal reports written by barristers, but in language diluted to the level of intelligence of the readers of that paper, with some of the hard words left out. The chemical organisation of this country can be greatly improved, the publications made more efficient, much time and much money saved, provided only that the chemists wish this to be done. Do they wish anything to be done? do they wish it so much that a few hundred of them are willing to spend say a couple of hours a month or half-a-crown a month towards that object?

* * *

For some time past it has been known that the British Dyestuffs Corporation has been negotiating with the Interessengemeinschaft—the German chemical combine familiarly known as the "I. G."—with the object, it was supposed, of arriving at an agreement similar to that made between the "I. G." and the chief dyestuffs company in France. This much was surmised, and only a few days ago a member of the late Government refused to make a definite statement as to the position on the grounds of expediency. Much surprise—indeed, the chemical dovecotes are fluttering with excitement—has therefore been caused by the publication in the *Manchester Guardian* of the outlines of what is claimed "on good authority" to be the draft agreement between the German and British interests. In brief, the "agreement" provides that the British firm shall have a monopoly of the British dye market, and a percentage share of foreign and colonial markets, at the same time receiving technical help and information as to manufacturing processes. In return, the "I. G." will receive a half-share in the profits of the Corporation, which will guarantee that any dyes it imports shall not be sold at prices higher than those charged abroad, but not what price shall be charged for its own manufactures. The *Guardian* further states that the agreement has been reached with the "full knowledge of the Board of Trade," and that it can be fitted into the framework of the existing Dyestuffs Act without any need for fresh legislation. The agreement, however, could not be worked without Government sanction, owing to the £2,000,000 invested by the State in the Corporation, or without the approval of the Board of Trade, which, with the help of an Advisory Committee, controls the grant of licences to import dyes.

* * *

It is, indeed, surprising, and already there are signs of the formation of a vigorous opposition to the proposal. We may again quote the *Manchester Guardian*, which says, in brief, that under the shelter of the Dyestuffs (Regulation) Act we have tried, "with conspicuous ill-success, to foster an industry which shows no signs of being able to stand on its own legs when the protection is withdrawn," and that "either the British company will become a mere selling agency of the German combine," or it will become a British monopoly, "capable of holding colour-users to perpetual ransom." With the questions of monopoly or protection or any other political problem of the kind we have nothing to do. But we and all chemists are very much concerned with the significance of the step. The flourish of drum and trumpet, with which the Corporation was founded, and the magnificent promises for the future of the fine-chemical industry are still fresh in our mind, though, to the general public, such things may be as discarded faded wreaths of long-past, forgotten feasts. However, that is another story now, for we are supposed to be at peace. Working agreements between companies of different nationality have been made before and, as far as we are aware, with beneficial results; some of our readers may remember the agreement made some years ago in the tobacco industry. But definite information as to the present agreement must be furnished before an opinion can be formed. What, we wonder, do Sir William Pope, Prof. Morgan, Prof. Green, and Dr. Levinstein think of the proposal? In the meantime, we await, with still greater curiosity, the dictum of that veteran author of works on the statistical aspects of political economy, Mr. Sidney Webb, now President of the Board of Trade.

* * *

The American Journal of Pharmacy a few weeks ago, published a paper by Mr. J. N. Taylor, on the definition of a chemical. This quoted the definition of the Synthetic Organic Chemical Manufacturers' Association. "*Chemical*—A material containing a preponderating proportion of an individual substance of definite elementary composition." Mr. J. N. Taylor referred to the editorial comment in our issue of May 18 last and to other definitions and suggests for consideration that *in the strictest technical sense every material thing is a chemical.* This is a very wide definition and we suggest a narrower one for the consideration of our readers. If we assume that matter is composed of elements and compounds of elements, and that a combination of elements to form a compound or a change in the manner in which elements are combined in compounds is a chemical change, it might be possible to state that all elements and all compounds are "chemicals" and that the noun "chemical" also includes such mixtures and solutions as are used for the purpose of causing or affecting chemical change.

THE EXTRACTION OF OIL FROM SEEDS, NUTS AND KERNELS*

By J. BREWIS

There are few mills in this country in a position to concentrate on the extraction of oil from one or two particular seeds. Fluctuations in the prices of seeds, oils, cakes, the frequent small margin of profit after crushing and the fact that the demand for certain cakes is seasonal makes such a procedure impossible for the majority of mills.

It may be necessary to extract the oil from cotton, til or rape seeds, soya beans, groundnuts, Babassu kernels, copra, palm kernels, shea nuts, mowha seed, linseed or castor seed, and as practically each of these seeds and nuts possesses some distinct peculiarity, calling for special treatment, few mills are in a position to handle the complete range in the most efficient manner. The method of extracting the oil is frequently a matter of compromise—to suit the available plant. The production of crude edible oil from certain seeds with limited plant is a familiar difficulty, yet some surprising results are obtained, for instance, from open-type presses, which were a few years ago considered unsuitable for rich oil-seeds. It is, however, impossible to recommend a definite type of plant to handle each seed with equal over-all efficiency, and the problem of obtaining the highest efficiency on a wide range of seeds on a particular plant is likely to remain—for the cultivation of the inventive faculty.

The raw materials of the English mill—the seeds, nuts and kernels, come from all corners of the earth; some are cultivated, others grow wild. They pass through so many and varied vicissitudes that the average good quality on arrival at the mill is surprising. We have no control over their production; they are bought on sample sometimes sent from the place of origin, but generally taken on the arrival of the parcel in this country. If the sample is collected in this country, it is assumed to have been taken in accordance with a definite custom and to be representative of the bulk. It may or it may not be so, for there are several factors which have a bearing on the over-all quality of a large parcel of seed.

Maturity of the Seed

If the seed is the wild-grown variety it is likely to be as varied as the blackberries on our hedges, and the native does not confine his attention to the ripe specimens. In the case of cultivated seeds, many of these (especially the small variety) are grown on small tracts of land farmed by a native, who decides very often the time of harvest not by the maturity of the seed, but the nearing religious festival, or the persistent attentions of the money-lender to whom he has mortgaged his crop.

The quantity of foreign matter in seed is very variable, and as it was not carefully distributed throughout the parcel at the place of origin the buying sample is not a reliable check. Until one has seen it done, the tendency for sand and stones to concentrate in certain bags is somewhat mystifying; nevertheless, unless engaged in the milling industry, we cannot but admire the generosity of the native who is prepared to sell so much of his native land for a handful of seed.

Further, the seed may have deteriorated on the voyage, due to heating, method of stowing. It may have been contaminated by other cargo or have been damaged by water. Analysis of the buying sample is not a reliable check on mill production.

The point for a critical inspection of the seed is at the mill intake for bulk seed, and the warehouse for bag seed. Here, when seed is to be used for the production of edible oil, is the opportunity to classify it and where necessary isolate undesirable batches. With bulk seed, lifted by means of a mechanical or suction-type elevator on to a band and discharged into bins or silos, it is easy to take a representative sample of each bin or silo. With bag seed it is more difficult, and the best solution appears to be to stack in definite piles. The respective silos and piles can then be classified in accordance with tests made on the warehouse samples, and seed sent to the mill can be blended to produce the desired grade of oil.

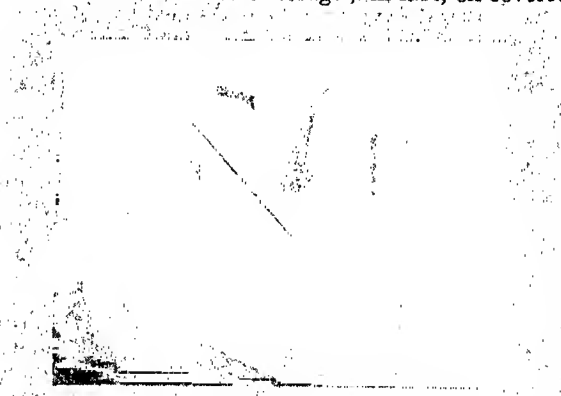
Cleaning the Seed

All seeds require cleaning in order to remove sand and foreign matter. Seed handled in bulk by pneumatic elevators is very free from sand on leaving the suction tube, but the more bulky foreign matter must be removed by screening. In the majority of mills the cleaning plant has to deal with all the undesirable material mixed with the seed, and it is generally placed in such a position that it can operate on the seed being transferred from warehouse to mill. Small seeds, rape, til, soya beans, linseed, can be very efficiently cleaned by means of the well-known revolving cylinder or reciprocating tray type of screen. Palm kernels and undecorticated groundnuts require more drastic treatment, owing to the amount of sand adhering to the skin and shell. Groundnuts taken from loamy soil are particularly troublesome in this respect, the indented shells being well adapted for holding the soil. Palm kernels and undecorticated groundnuts should be passed through a revolving inclined cylinder, sometimes termed a "tumbler," and the soil loosened by the action of the nuts rubbing together. The cylinder is sometimes perforated to allow the sand to pass out through the circumference; the more efficient arrangement is to use the "tumbler" only for the purpose of loosening the soil and to effect separation on a shaking tray screen.

The use of the tumbler type of cleaner for dealing with palm kernels is by no means general in this country, and a short explanation of the reason for its application may be useful, as palm-kernel oil is generally produced for edible purposes. The ordinary shaking tray screen deals only with the loose dirt and sand; it does not remove the sand and decayed vegetable matter attached to the skin of the kernel. In mills using only the shaking tray cleaner this can be verified by inspecting the condition of the feed

* Paper read at the joint meeting of the Liverpool Section of the Society of Chemical Industry and the Chemical Engineering Group on December 12, 1923.

roll and housing of the first break rolls, and sufficient evidence will be obtained to prove that the amount of foreign matter adhering to the kernel skin is considerable. This foreign matter is generally collected by kernels which at some time in their history have had their skin covered with oil drawn by heat of the sun or unsuitable storage; in fact, oil-covered kernels frequently reach the mill. The duty of the tumbler is to remove this attached foreign matter, and if the kernels are wet, also to remove the oil from the skin, otherwise the final oil produced is likely to taste "harsh" even after being neutralised.



Cottonseed Cleaning Plant

Fig. 1

The partial closing of coconut meat during drying forms a pocket for the accumulation of dirt, and the fine dust due to the action of weevils. This is shaken out by allowing the copra to fall over a series of steps on to a shaking tray screen.

The cleaning of woolly cottonseed is a problem which has received much more attention in America than in this country. This is, no doubt, due to the fact that in the early days of cotton-seed crushing in this country, the seed was mainly the Egyptian variety, which has no adhering cotton and is known as "black" seed. When the woolly varieties arrived the crusher was eventually faced with the problem of removing, in addition to loose sand and stones, the dirt in the lint. The evolution of the plant appears to have remained entirely in the hands of the crusher. English mills dealing with woolly seeds are equipped with cleaning plant which is more or less their own design and manufacture, or with American plant.

Woolly seed may be divided into two classes:—

1. Seed with fairly long outer lint covering a short tough fibre firmly attached to the seed husk.
2. Seed with no long lint but covered with the short tough fibre.

To obtain the best possible yield of oil from woolly cottonseed milled on the undecorticated system, the long lint and short fibre must be removed, the seed should be sent to the mill as [illegible] as possible, otherwise the lint will absorb oil and the cake have a rough and, from the farmers' point of view, unattractive appearance.

Certain varieties of woolly seed, even when efficiently delinted, yield a very low percentage of oil, and as the cost of delinting is a considerable item, it requires careful supervision, as it may not be advisable to carry the process beyond a certain stage.

The lint has a market value, depending on its freedom from dust and pieces of seed hull and dirt, its length of fibre, whiteness. Apart from the length of fibre, the quality of the lint produced depends on the efficiency of the cleaning and the method of removing it from the seed. For the moment we are concerned with the cleaning of the seed and lint covering it.

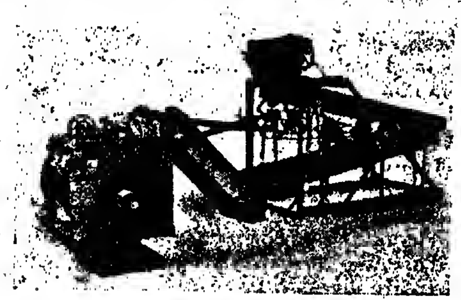
The removal of loose material from the seed is easily accomplished; the difficulty is to remove the dust and dirt from the lint. Plant used for the purpose of separating loose material and removing the dust from lint is shown in Figs. 1 and 2:—

Seed and Lint-cleaning Plant

For seed without long lint and covered with the short fibre only, the methods of cleaning described are quite efficient, but for dealing with seeds covered with long lint closely wrapped around the seed they are not efficient. It is impossible to remove the dust unless the long lint is opened out. If this could be accomplished the appearance of the lint finally obtained would be decidedly improved. The problem has in the past received much attention, but the tendency now is towards more intensive ginning and, consequently, less lint on the seed.

The removal of the lint or short fibre from the seed is accomplished in a variety of ways. For the removal of the long lint a modified form of saw gin is in general use. The Carver linter is representative of this type, Fig. 3.

In setting up the linter saws, full advantage should be taken of the seed being in contact with the side



Cottonseed Cleaning Plant

Fig. 2

of the saw teeth. The teeth should be sharpened in such a manner that as much "burr" as possible is left on the side of the teeth. This can be done by using the gummer after filing, and setting the gummer centre slightly behind the saw.

When seed has fairly long lint, it is sometimes the practice to double lint. The seed is first run through the linter at its maximum capacity and with dull saws, and then a second time with a normal feed and

sharp saws. This method produces a grade of first-cut lint free from husk and of a good colour but not free from fine dust. It will be noted that a large proportion of the dust released by the opening of the lint by the linter saws is blown back into the lint as it collects on the reel.

The removal of the short fibre is effected by passing

Linting Machine

Fig. 3

the seed between carborundum rolls. There are also machines of the defibrating type in which the short fibre is torn from the seed by the abrasive action of metal surfaces formed like a household grater.

In England, cottonseed, having been cleaned and delinted, is sent to the mill and the oil extracted on the undecorticated system, that is, the entire seed, hulls and kernels pass through the presses. In America, where the seed is decorticated, the hulls being separated from the kernels (or meats), the meats only pass into the mill to be pressed. Much has been said and written in order to induce English crushers of cottonseed to introduce the decorticating system into their mills. Among the advantages claimed for the system, the following appear to be the most important.

1. It gives a higher yield of oil.
2. The oil is of better quality than that produced from undecorticated seed.
3. The oil is refined more easily and with less loss.
4. The cake is a highly concentrated cattle food, more easily digested than the undecorticated cake.

The accuracy of items 1, 2 and 3 is generally admitted; the yield of oil on the decorticating system is on an average $1\frac{1}{4}$ to $1\frac{1}{2}$ per cent. greater than on the undecorticated system, the comparison being made on seeds of similar initial oil distribution.

Regarding the cake, the relative merits of decorticated and undecorticated cake as a food for English cattle is still a matter of controversy. There are those who maintain that the presence of the hull is necessary to meet the conditions and methods of feeding prevailing in this country. There may be some truth in this, and the argument is not without support. The greatest obstacle to the extension of cottonseed crushing in India is the system of feeding cattle with whole seed. The decorticated cotton-cake is not in demand, but such mills that produce it have no difficulty in disposing of the hulls to local farmers.

In this country, the controlling factor appears to have been the type of cake demanded by the farmer. If there had been a growing demand for the higher priced decorticated cake, the introduction of the means of producing it would have received more serious consideration.

Decorticating Plant

Decorticating plant for working on the double huller system is shown in Fig. 4. The first huller is set to cut about 85 to 90 per cent. of the seed. The large seeds are cut and the small seeds allowed to pass uncut. By this arrangement the larger seeds are cut without being pulverised and the small seeds pass to the second huller which can be adjusted to cut the remaining 10 to 15 per cent. The product from the first huller is discharged on to the double shaker and the hulls and coarse meats separated. The hulls and uncut seed pass to the first beater and the meats to the mill. In the first beater the fine meat dust is beaten out of the hulls and lint. The hulls and uncut seed then pass to the second huller where the remainder of the seed is cut; the product being dropped on to the second shaker for the removal of the remaining coarse meats. The hulls then pass to the second beater for the removal of the meat flour or dust. The hulls are now finished and are removed from the plant. The meat flour discharged through the mesh of the beaters contains small pieces of hull and lint, and on the intensive system of decorticating is not fit to mix with meats passing to the mill. It is, therefore, given a further treatment by the beater finishing screen, the flour passing through the screen to the meat conveyor, and the fine pieces of hull and lint to the last beater and thence into the hull conveyor. There are several other methods, each claiming

Decorticating Plant for Cottonseed

Fig. 4

some particular merit, for instance, the use of a knife huller for first hulling. It being claimed for this method that practically the whole of the seed is cut in the first machine, and that the cutting is more efficiently carried out than in the percussion type of huller, and that the absorption losses are lower. There is also the method by which a certain

amount of fine hulls is returned to the meats. Again there is the method of decorticating "black" seed in which the hulls are withdrawn by means of fan-suction.

During the process of decorticating linted cottonseed, there are two sources of loss known as the separation and absorption losses. The first is due to incomplete separation of hulls and meats; the latter is due to oil absorbed by the hulls and lint.

To obtain ideal conditions the seed should be cut in such a manner that the kernel or meat is not broken or pulverised, and the separation of hulls and meats should be effected as soon as possible. In actual practice, ideal conditions do not obtain, due to variations in the size of the seed and wear in the huller knives and plates; each seed is not cleanly cut, and a certain amount of pulverising takes place. This results in the production of meat flour, which adheres to the hulls and lint. Further, the seed should be cut as few times as possible, for repeated cutting, in addition to producing "flour," draws oil from the meats; this is absorbed by the hulls and lint, and cannot be recovered. An estimation of the efficiency of the process depends on, first, the percentage of hulls mixed with the meats; secondly, the percentage of oil absorbed by the separated hulls. A separation of 98 per cent. meats from hulls appears to be common with modern American mills; in fact, some claim higher efficiency. With seed properly prepared by delinting and hullers in good condition, there appears to be no difficulty in keeping the oil loss in hulls below 0·5 per cent.

It will have been noted that the system is very exacting; it demands very definite requirements in order to obtain the highest efficiency. The American mill, which deals with seed stable in character and consistent in oil content, has no difficulty in meeting these conditions.

This is not so with the English mill, which may have to deal with many varieties of cottonseed, varying in oil content and character, a large proportion being "black" seed. Again, the demand for cottonseed cake is seasonal, and during the off-season it is usual for the English mill to turn to other seeds, in which event the decorticating plant standing idle would add considerably to the unproductive capital charges. It is not surprising, therefore, that the English crusher has, up to now, remained unconvinced by the arguments advanced in favour of its adoption, and after cleaning and delinting the seed sends it to the milling plant undecorticated.

All seeds should pass over a magnetic separator before milling, cottonseed being passed before delinting. The most suitable place for the separator is at a point where the seed in transit is a minimum, obviously just sufficient to feed the mill. Large pieces of iron are removed by the cleaning plant, and the function of the magnetic separator is to collect the small pieces, which seem to have an affinity for prize cattle of fabulous value.

MILLING, ETC.

The subsequent operations for reducing, milling, cooking and pressing the seed are interdependent, and any attempt to isolate one of them so that it does not fulfil its functions in meeting the requirements of the others is soon apparent. The effect is, of course, more marked on certain seed. The effect is also cumulative—for instance, unsatisfactory milling may be the cause of imperfect cooking, resulting in excessive "foots" at the presses. In practical seed crushing there is no such thing as efficient reducing, milling or cooking considered independently; the only efficiency of any use is their combined efficiency. It has already been pointed out that the method of carrying out these operations is frequently a matter of compromise—to suit the available plant. It would appear, then, that in considering the plant used in reducing milling, cooking, and pressing we should not emphasise type unduly; for there is considerable difference of opinion as to the best type of plant for dealing with a particular seed or carrying out a certain operation.

The introduction of rich oilseeds and the demands for crude edible oils revolutionised oil milling. Methods in vogue for the extraction of oil from cottonseed, linseed, rape and other small seeds were found to be unsuitable when applied to palm kernels, groundnuts and copra. It was found that these latter required much more intensive methods, and heavier finishing rolls and presses were introduced. In the case of groundnuts and copra, the large amount of seed squeezed out of the press (foots) and the destruction of press cloths led to the introduction of the closed type of press with either fixed or movable cages. The difficulty in making a hard firm cake brought about the use of the closed press for palm kernels. The pressure applied to the cake has increased enormously—from 0·6 tons to 4 tons per sq. in., with a consequent increase in the cost of pressing plant.

During the introduction of these heavy cage presses, the gross pressures of the Anglo type press were also increased by greater ram area, and increased pressure in the hydraulic system. Further improvements in connexion with the Anglo system, such as increased cooker capacity, vastly improved cake-forming machines, together with a more intimate knowledge of the behaviour of rich oilseeds during the various processes, gave the system a new lease of life.

Opinion is now very divided as to the relative merits of the closed and open type of press. For obtaining a high oil-yield from a wide range of seeds hot pressed, the Anglo system is now considered by many crushers to be even more efficient than the closed pressing system.

There is now no difficulty in producing with the Anglo press, having a gross pressure of approximately 500 tons, palm-kernel cake containing only $5\frac{1}{2}$ per cent. of oil. The heavy cage press with a ram pressure of 970 tons does not improve on this; in fact, if the press is filled without mats, as is usual with palm kernel, the oil left in the cake is generally

nearer 6 per cent. The pressure on the cake in the open press is 1 to $1\frac{1}{4}$ tons per sq. in. and in the cage press 2·8 tons per sq. in.; the length of time under pressure is practically the same.

The press bagging in which the Anglo cake is wrapped provides a large area for the free flow of the oil. This, taken in conjunction with the fact of the full ram load being applied to the cake the whole of the time the press is open to pressure, offers a reasonable explanation for the better performance of the Anglo press. During the later stage of pressing with the cage press, the oil has to travel a very difficult path, and the pressure on the cake varies, due to the friction between the cake and cage.

The main objection to the Anglo press for pressing palm kernel is the unsatisfactory cake produced with a pressure that will keep the cost of press bagging within a certain margin. The cake is easily broken, even after storage, and is not suitable for transit in bulk. In fact, palm-kernel cake made in the cage press with a pressure of 3 tons per sq. in. on the cake is not now considered satisfactory. The latest cage-pressing plant for palm kernel is arranged for a pressure of 4 tons per sq. in. on the cake and a gross ram pressure of 1300 tons.

The utility of such a plant for other seeds, for instance, groundnuts and copra, is questionable, for these do not require such intense pressure for the production of firm cakes. In fact, in the case of groundnuts it is in the home trade a frequent complaint that cage press cake is too hard.

Here again (dealing with groundnuts), the cage press requires a greater pressure per sq. in. on the cake than the open press for equal oil yield, and the troublesome "foots" associated with decorticated groundnuts is not entirely eliminated by the use of the closed press. It is very difficult, when using heavy cage presses with large ram area to regulate the speed of the ram, to keep the quantity of oil drawn within the capacity of the cage drainage. The trouble occurs during the early stage of pressing, and if the ram is allowed to rise too rapidly more or less meal is washed out of the top and bottom of the cage. This restriction in speed of working together with the use of mats reduces the output of groundnuts considerably below that of palm kernel. The increase in size (due to wear) of the perforations which form the drainage area must also be taken into account, for as these increase in area so does the quantity of "foots." In the case of plate cages the perforations are usually 0·03 in. dia., and an increase to 0·04 in. makes an appreciable difference in the quantity of "foots," and the labour required to keep the cage chambers clean.

For dealing with rich oilseeds, and for cold pressing, the cage press has decided advantages, but for dealing with a wide range of seeds and producing a high oil yield, the Anglo or open type press, with its simplicity and low upkeep costs, is by no means supplanted. It is yet the utility plant of the mill.

The highest possible yield of oil is not the only consideration in seed crushing; the production of cake that will satisfy the requirements of the farmer must also be taken into account. The average farmer is now quite alive to the value of oil in the cake he uses, and that cake containing a high percentage of albuminoids and a low percentage of oil is not desirable. Further, he places particular value on the kind of oil: for instance, of linseed and cottonseed, linseed cake is certainly the most popular, mainly owing to its high oil content.

Cakes are now sold guaranteed to contain a certain percentage of oil, and actually the oil content is higher than the guarantee.

The oil content of the most important straight feeding cakes is given below:—

	Per cent.
Linseed cake	7–8
Coconut cake	$6\frac{1}{2}$–8
Groundnut cake	7–8
Palm-kernel cake	$6\frac{1}{2}$–8
Cottonseed cake	5–6

Owing to the amount of oil required to be left in the cake made from certain seeds, it is neither necessary nor the practice to make extraction as intensive as possible, and in using the open press the length of time the cake is under pressure is reduced, with a corresponding increase in output. Open type presses, arranged four presses per "side" or battery, are usually filled and discharged at the rate of six pressings per hour from the four presses, when the highest oil yield is desired. For the production of cake to contain a higher percentage of oil, seven or eight pressings per hour are taken from the four presses. This statement, however, requires some qualification; for in pressing rich oilseeds it is not possible to work the open press at the higher speeds, owing to excessive "foots." The open press does not then compare so favourably with the cage press.

Small seeds, such as rape, cotton, soya, and til, are, after cleaning, ready for the finishing rolls. The larger nuts, such as palm kernels, groundnuts, copra, require a preliminary reduction. Two pair reduction rolls are suitable for ground nuts, and for copra after it has been rough broken to the size of a palm kernel.

For dealing with palm kernel a three pair machine is generally used. A much better method is to use two of the two pair rolls in series, giving four gradual reductions instead of three. The reduced kernel is a more even grade and cleaner cut than is possible with the three pass machine. Further, with the three pass machine, the rolls have to be set so close that the grade of kernel passing is larger than the space between the rolls, consequently the kernel is excessively squeezed and oil is drawn. It is then impossible to obtain satisfactory results during final milling and cooking.

Five high finishing rolls are arranged to give four passes to the seed, each pass increasing in intensity due to the increasing superimposed weight of the rolls. This type of finishing roll is used for all varieties of seed. The usual size is five rolls 16 in. dia. by 48 in. long, but a better arrangement for the modern mill is 18 in. by 16 in. by 48 in., the three alternative rolls starting from the top being 18 in. dia. For milling palm kernels in rolls of this size and weight, eight passes are necessary and double milling is applied, two sets of rolls being

run in series. The recognised size of mill for palm kernel has rolls 24 in. dia. by 42 in. long, arranged five high.

The object of milling is to reduce the seed to the thinnest possible flake without drawing oil. If oil is drawn, the product from the rolls is a sodden mass, very difficult to deal with in the cookers. Further, with edible oils there is the risk of contamination due to oil-wet seed accumulating on the housing and becoming rancid or forming a medium for the creep of lubricating oil from the roll bearings.

The older mills are not well equipped for dealing with the rich edible oilseeds. They are generally so arranged that the milled seed is transferred from the rolls to the cookers by means of spiral conveyors. This answered very well for such seeds as cotton, linseed or soya, for the conveyor blades pulverised the seed and broke up the flakes. With palm kernel, groundnut, or copra, the pulverising action of the blade, and the squeeze which it gives to the milled seed in pushing it past the conveyor bearing is decidedly detrimental to efficient results in the cooker. Such conveyors are another source of contamination, for the seed collects the grease used to lubricate the intermediate bearing and the rolled seed which accumulates between the spiral and the conveyor casing is generally rancid. It is obvious that in the production of high-grade edible oils every source of contamination should be avoided. The modern mill is so arranged that the mechanical conveying of the seed after milling is entirely eliminated, and once the seed is opened out it is put through the intermediate processes and transferred to the cooker as soon as possible.

The remarks made concerning the intensity of final milling require some qualification when applied to decorticated groundnuts. Here there is no difficulty in breaking up the oil cells. The difficulty is to produce a milled product that will not ball in the cooker, and which will unite and stand up to the pressure in the press. It is a common practice to mill the decorticated nuts, whole, without any preliminary reduction. This is quite satisfactory provided a large proportion of the flake does not fall to "flour" and fine particles. It would appear that the best objective is to produce the thinnest firm flake with the minimum of flour possible, and as the flour comes from the edge of the flake it is obvious that the number of passes in the finishing rolls should be kept down by slightly reducing the nuts in a breaker. There is this advantage in breaking the kernels that a considerable amount of red skin is released which can easily be removed by passing the kernels under a fan suction.

It is, however, impossible to mill decorticated groundnuts without producing a certain amount of "flour" and fine nut meal, and as this forms the binding medium in the cooker, and prevents regular and even cooking, and also prevents the main particles of the cake coming to rest under pressure, both the flour and fine meal should be removed. This is easily done by passing the product of the finishing rolls over a short scalper.

Extraction of Oils by Means of Solvents.

For many years the pressing or expression system stood alone in this country as the only efficient means of obtaining oil from seeds. The cake gradually became established as a cattle food, and the farmer is now quite familiar with the residue of certain seeds in the form of cake. His system of cattle feeding is built up on its use. Further, many of the standards of value for oil and cake were based on the capacity of the pressing system, and have been revised as the system improved.

When the solvent system of extraction was introduced, one of the most difficult problems which had to be solved was the disposal of the residue, which in the form of meal contained much less oil than the standard cake made from similar seed. The increasing demand for compound feeding stuffs solved the problem—the solvent-plant meal became a recognised ingredient in the manufacture of sweetened meals, compound cakes, cubes, etc. At first it was used very sparingly owing to the prejudice against its use on account of low oil content and frequent trace of solvent. Improved methods and the use of more suitable solvents facilitated the production of solvent-free meal, and the value and use of a low oil-content ingredient for the compound mix is now fully appreciated.

The increasing demand for meals, etc., also brought about the extraction of oil from a larger variety of seeds by the solvent method, and although it is not suggested that the solvent-plant meal will entirely take the place of cake meal in the compound mixtures, it is being used in increasing quantity. Further, there is a decided tendency to produce meals of such oil content that will permit them to be used more freely than heretofore. As the guaranteed oil content of compound feeding stuffs is fixed much higher than that in the usual solvent-plant meal, the quantity which can be mixed with other ingredients of normal oil content is obviously limited.

The solvent system has developed rapidly since the war. There are now several plants each dealing with close on 1500 tons of seed per week. Undoubtedly (allowing for wage fluctuations, common to both systems), the cost of extraction by the solvent method has been considerably reduced during the past few years. This has been brought about by increased production per unit (usually considered as 4 pots), reduced solvent losses, cheaper solvent, and less consumption of steam.

Owing to the fact that the system lends itself to increased output without labour interference, there is every incentive to a still further increase per plant unit.

[illegible] the production of crude edible oil, the question [illegible] suitable solvent is important. It has been proved by experience that for the higher quality oils, the solvent must comply with certain definite requirements. The unsatisfactory solvents and crude distilling plants used in the early days did much to retard the progress of this system of oil extraction.

For the extraction of oil from seeds a solvent should contain no traces of any compound capable

of undergoing chemical change during the extraction process. It should have a close range of distillation, not too low to encourage loss, nor so high as to require a final temperature of evaporation injurious to the oil. It should not be soluble in water and it should have a distinctly different gravity from water. A table showing the characteristics of some of the available solvents is appended:—

Solvent	B.P. (° C.)	Sp. Heat	Latent Heat cal. 1-gram	Price per gall s.	d.
Ether	34·6	0·33	90	4	0
Carbon disulphide	46·2	0·24	83·8	3	7
Chloroform	61·2	0·23	58·5	25	2
Alcohol (methylated spirit)	78·1	0·6	205	3	1
Carbon tetrachloride	76·7	0·2	51	6	2
Benzol (pure)	80·3	0·41	93·4	1	7
Benzol (commercial)	79–125	0·408	95	1	3
Trichlorethylene	87	0·233	56·6	5	3
Petroleum spirit	100–120	0·425	73·5	1	6
Tolual (pure)	110·8	0·404	—	1	10
Turpentine	0·59	0·41	74	4	10

For general suitability there has up to quite recently been nothing comparable to the specially prepared petroleum spirit. It has a satisfactory boiling point, and a sufficiently close range to place it on an equality with the constant boiling solvent. Further, the standard grade which has been proved to be suitable for the extraction of edible oils, can be obtained at a reasonable price. Unfortunately, it is inflammable, and its use adds considerably to the insurance charge on plant and buildings, especially in a congested district and owing to the special precautions which have to be taken in the arrangement of artificial lights it is difficult to obtain good plant illumination.

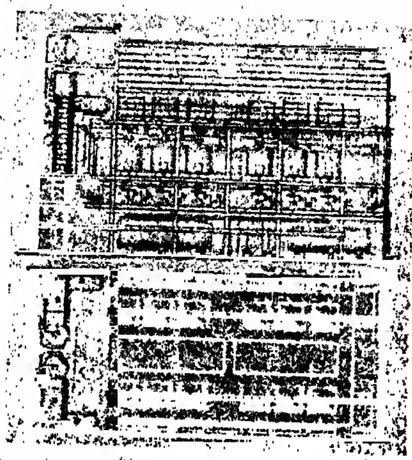
Within recent times, trichlorethylene has come into prominence for the extraction of oil from seeds, and it would now appear to be conclusively proved that in addition to being non-inflammable, it possesses in use the following advantages compared with petroleum spirit (benzene):—It has greater penetration; solvent losses are smaller; there is increased production per plant unit, and lower steam consumption for evaporation.

There is considerable difference of opinion as to the suitability of this solvent for the production of edible oils; this can only be decided when the solvent comes into more extended use.

The high cost of trichlorethylene compared with that of benzene is against it coming into rapid general use for oil seeds. The cost of solvent with plants using benzene is not now such a serious matter as formerly, when losses were anything up to 7 gallons per ton of seed; and solvent cost 2s. 6d. per gallon. The modern plant with a solvent loss of 3 gallons (benzene) per ton of seed and obtaining solvent at 1s. 6d. per gallon is not likely, on the face of it, to look very favourably on trichlorethylene at 5s. 3d. per gallon. To arrive at a fair comparison the conditions appertaining to the particular plant likely to use it must be taken into account. Further, in order to make perfectly sure that full benefit may be derived from the higher working efficiency of trichlorethylene, the capacity of the plant details must be checked. It is frequently stated that more patent specifications are drawn up for rotary pumps than any other appliance, but the number for solvent plants must be a good second. It is astonishing how few of these patents have been put into actual working. The type of extractor pot used appears to be fairly common and has a capacity of 2 to $2\frac{1}{2}$ tons of seed. It is stationary and the meal is agitated by means of stirrers fixed to a vertical shaft.

In other details of the plant there is considerable variation. There are also several methods of washing the seed with solvent.

For the extraction of oil by the solvent process, the seed is reduced by milling in a similar manner to seed being prepared for the pressing process. The milling does not, however, require to be so intensive, in fact, very finely milled seed, which will pack



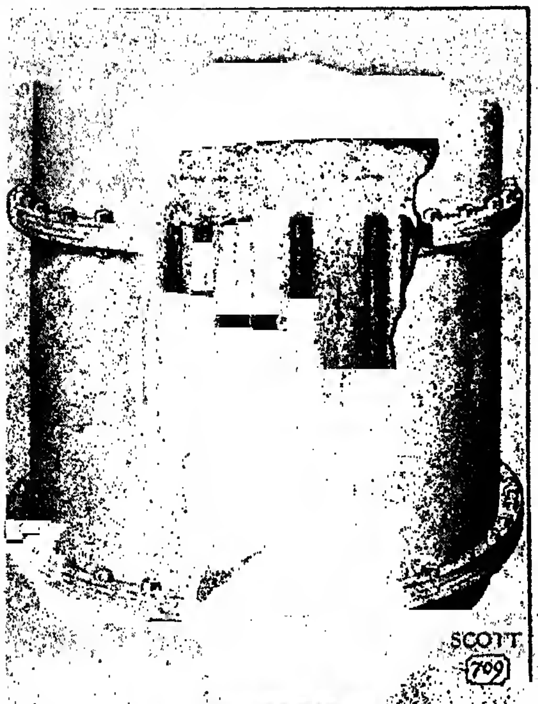
Solvent Extraction Plant
FIG. 5

close, interferes with the draining of the charges of solvent, and is one of the causes of the trouble known as "zoning"—one or more portions of a charge of seed acting as separate extractors.

It is well known that if a charge of seed is washed with successive washes of clean solvent, the amount of oil in the solvent is less and less—as the number of washings increase the solvent is used less and less efficiently. The last washings contain so little oil, they could be used to better advantage as solvent for a fresh charge of seed. This is done in the counter-current method of washing. In this method of working each charge of solvent is used on seed containing more and more oil, or in other words, each charge of seed is treated with solvent containing successively less and less oil. Finally the solvent washes a fresh charge of seed, is fully concentrated and removed to the still for separation. Originally the method was operated on the continuous system, a number of extractors being connected in series. Eventually the discontinuous method came into use, as it was found that by keeping the solvents of

different concentration entirely separate, the same degree of extraction could be obtained with a less initial volume of clean solvent.

The well-known experiment with the glass beads coated with a soluble substance, demonstrates the wisdom of the change and that the only way to obtain a high percentage extraction with a given volume of solvent is to use it in batches and to drain off one batch before applying the next. This is the principle on which plants using petroleum spirit are operated. There are plants in use at the present time working on the discontinuous counter current system. The batches of solvent in each extractor are in rotation pumped from one pot to the next in sequence. The modern plant, although differing in the method of transferring the batches of solvent, retains the advantage of the counter-current method in that it is worked on the gradual enrichment system.



Circulation in Scott Stripping Still

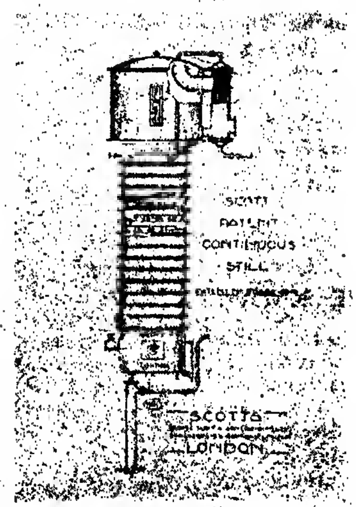
Fig. 6

The modifications in the method of transferring the solvent are due to the obvious disadvantages of the older arrangement, which makes the plant very rigid in operation. The transfer of the batches of solvent direct from one extractor to another by means of a pump makes the system very non-elastic, for if there is delay in carrying out an operation in the progress of one of the extractors, the progress of two other extractors is delayed. Further, the withdrawal of the solvent by means of a pump frequently zones portions of the charge.

The modern plant shown in Fig. 5 is so arrange that the extractors are entirely independent, eac batch of mixed solvent drains by gravity to a tan containing solvent of similar concentration.

In a large plant arranged for rapid manipulatio it is necessary to return the solvent to the store fc re-use, as quickly as possible. Further, the separa tion of the oil and solvent should be effected by th least possible consumption of steam. It is no usual to employ a stripping still in which the bul of the solvent is driven off by closed steam. I order to avoid risk of discolouring the oil due t over-heating, a stripping still should be arranged fc rapid circulation, and should have no pockets c stagnant liquor in contact with the heating surfac The circulation of a well-known type of strippin still is shown in Fig. 6.

The last trace of solvent should be removed fro the oil by means of open steam, the oil (with trac of solvent) is transferred from the stripping still t the finishing still (Fig. 7), and the solvent con pletely driven off. The complete plant consistin of stripping and finishing stills is shown in Fig. 8.

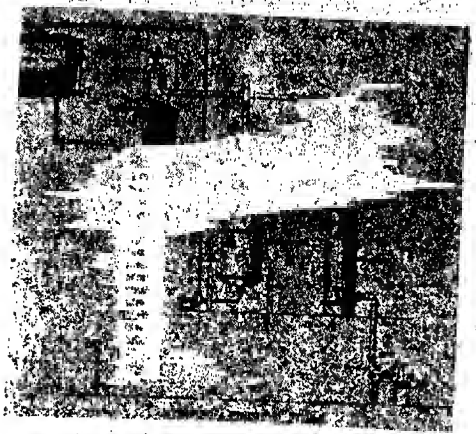


Finishing Still

Fig. 7

In making a comparison of the two systems extraction the advantage of the solvent method i point of oil yield stands out very prominent. Tl average oil in press cakes being 6–6½ per cent., i solvent-extracted meal 1·5 per cent. With sec residue which cannot be used for cattle food ar practically refuse, the high yield of oil given l the solvent system leaves it without a competit in the treatment of such seeds. Where the sec residue is required in the form of a straight feedir cake, then the solvent system cannot compete, bu if the cake is to be ground and used as an ingredie for compound mixing, then when treating certa seeds the solvent plant producing a meal residue h an advantage.

Due to the varying methods of operating pressing plant it is somewhat difficult to arrange units for the purpose of comparison with a unit solvent



Stripping and Finishing Stills
FIG. 8

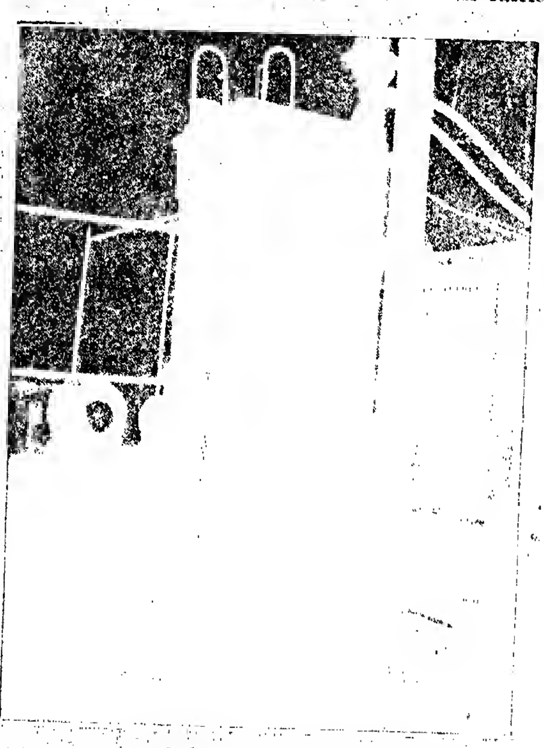
plant. Taking the unit solvent plant as four extractors the following appears to be a fair average :—

	Output Tons per week	Men required per shift
Cage presses (mov. box)	270–300	5–6
3 Batteries of A.A. press.	270	10
4 Extr. solvent plant	260–280	3–4

THE KNOWLES COLUMN CELL

A very serious drawback to the use of electrolytic cells for the production of hydrogen in large volumes has always been the great floor space required, so that the cost of housing electrolytic-hydrogen plants of large capacity has always been a serious item of capital expense. With recent developments in the synthetic ammonia and similar industries the question of floor space has become very prominent, not only on account of the exceptionally large plant required, but also because such plants have usually to be installed where much expensive excavating work is necessary to provide a level area for the cell room, the source of power being usually hydro-electric and the site for the works nearly always in mountainous districts. Previous to the introduction of the Knowles column type cell, floor area has only been reduced by increasing the depth of the electrodes and running them at very high current densities, a practice which reduces the life of the cell and increases its internal resistance, resulting eventually in a serious loss of efficiency. Even with cells having exceptionally deep electrodes run at very high current densities the floor area cannot be very greatly reduced and anything saved in the initial cost of the buildings is lost in the far greater cost of upkeep of plant.

The Knowles column plant, on the other hand, has electrodes of only moderate depth running at low current density and yet occupies only a fraction of the floor area required by any other make of plant. The general design of each cell does not depart in any way from the best principles of electrolytic-cell design, but the superimposed arrangement adopted is, however, entirely novel and enables a plant of large capacity to be installed on an exceptionally small area. Fig. I. illustrates the original experimental cells, a design which has since been considerably altered; only two cells are shown, but in practice the cells are erected ten high. The current passes directly from each cell to the cell above, without any external connexions, the polarity being reversed as it passes out from one cell to the next, and the only electrical connexions required are to the bottom of the lowermost cell and to the cover of the upper cell of each column. Upstanding electrodes on the base of one cell alternate with electrodes hanging from the base of the cell above, and form the anodes and cathodes, respectively, of each cell unit. Abestos diaphragms suspended from the dividing or bell plate surround the hanging electrodes and prevent the gases from mixing. The containing tank, the inner surface of which carries



The Original Experimental Cells
FIG. 1

an electrode, is built up of four iron castings bolted together and is designed to carry the weight of the cells above. All the tanks are identical and interchangeable, so that any tank may be used for the

bottom cell without risk of failure from the weight above. The base of the tank to which the electrodes are fixed is bolted on a projection to form an electrolyte-tight and gas-tight joint. Suitable electrolyte-separator, gas-offtake and feed water pipes are provided, and the tanks of adjacent cells are insulated from one another by special jointing rings which form a gas-tight joint. There is no possibility of a short circuit occurring between adjacent tanks owing to any electrolyte which may drip from a faulty pipe connexion on the cell above. Owing to the weight of the cells and electrolyte, no bolts are necessary to make the joint between the tanks gas-tight, and erection or dismantling therefore simply consists in lifting one cell complete with electrodes from the cell below. Straight copper bars bolted on both sides of lugs extending the whole length of the electrodes carry the current between the top cells and bottom cells of adjacent columns.

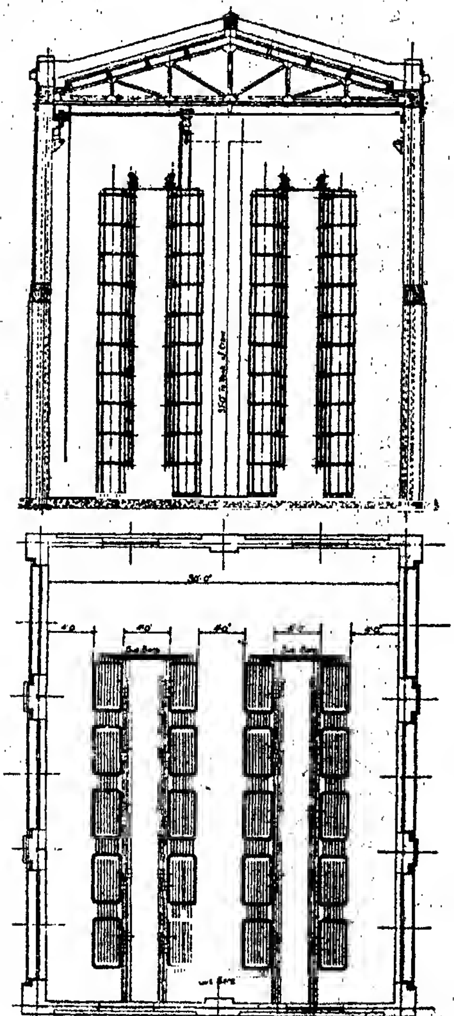
The same quality of steel plate which has proved so durable in the earlier pattern of cell is used for the electrodes in this cell, the section of the electrodes throughout being ample to carry the current for which the cell is designed without appreciable loss. The anodes, which in one column are the upstanding electrodes and in the next the depending plates, are treated with nickel by a special process which ensures entire freedom from corrosion and also reduces over-voltage. For the diaphragms asbestos cloth of close weave and free from flaws, to ensure complete separation of the gases, is employed, and the material lasts not less than three to five years. Material chosen for its lasting qualities and high insulating power in the presence of caustic soda is used for the joints between the cells and the base plate and tanks. Since the tank walls do not carry any current, the electrical conductivity of the cast iron used is unimportant and it is possible to use a quality specially suited to withstand large crushing stresses.

Comparing on the basis of equal efficiency and taking a 1000 kw. plant generating 7200 cb. ft. of hydrogen per hour, the Knowles column cells occupy less than one-third of the area taken by several other cells, despite the fact that the current density is low and the depth of the electrodes is less than in any other cell considered.

The multi-electrode construction permits cells to be built for any current from 1600 amperes upwards by simply increasing the number of electrodes per cell without departing from the standard design. Normally the cells run at 2·25 volts per cell, but can run at any voltage up to 25, at which figure the gas production is 50 per cent. above normal. The voltage may also be reduced to 2 volts per cell, representing a decrease in current consumption of 40 per cent. below normal, and a corresponding decrease in the gas output. This flexibility in operation is of great importance where the cells are to be used in connexion with "off-peak" power schemes where the power available varies greatly during the day.

Safety devices make the cells practically fool-proof in operation and only pure gases can pass into the offtake pipes under any conditions of pressure and electrolyte level. Both gases are of exceptional purity and the oxygen is guaranteed to be not of less than 99 per cent. and the hydrogen of 99·5 per cent. purity. Test runs carried out over long periods show that the average percentage purity is oxygen 99·6 and hydrogen 99·9.

A typical layout for a plant of 4780 kw. capacity generating 31,100 cb. ft. of hydrogen at maximum output is shown in Fig. 2. The cells are arranged in 20 columns, each consisting of ten cells, the total



Arrangement of 200 Knowles Patent Column Cells

Fig. 2

area of the cell room, including gangways being only 1200 sq. ft. A large plant of this type is now under construction of Bussi, Italy, for the Società Italiana di Elettrochimica.

FORTHCOMING EVENTS

Feb. 4. SOCIETY OF CHEMICAL INDUSTRY, *London Section* Joint meeting with the *Chemical Engineering Group*, The Engineers' Club, 39, Coventry Street, London, W. 1, at 8 p.m. "The Manufacture of Potash and Other Salts from Leucite," by Prof. J. W. Hinchley. To be preceded by an informal dinner.

Feb. 4. THE INSTITUTE OF CHEMISTRY, *Manchester Section*. Annual Social Meeting, to be held at The Grand Hotel, Manchester, at 7 p.m.

Feb. 4. BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY, Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "Glass and its Chemical Nature," by D. G. Skinner.

Feb. 4. INSTITUTION OF RUBBER INDUSTRY, The Kelvin Room of the Engineers' Club, Coventry Street, W., at 8 p.m. "The Use of Rubber Latex in the Manufacture of Boards, Leather and Linoleum Substitutes, and as to the Vulcanisation of these Products," by F. Kaye.

Feb. 4. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 8 p.m. "Colloid Chemistry" (Cantor Lecture), by E. K. Rideal, M.B.E.

Feb. 5. SOCIETY OF CHEMICAL INDUSTRY, *Edinburgh and East of Scotland Section.* Annual Dinner with the local Section of the Institute of Chemistry.

Feb. 5. SOCIETY OF CHEMICAL INDUSTRY, *Birmingham and Midland Section*, University Buildings, Edmund Street, Birmingham, at 7.15 p.m. "Some Studies in the Kinetics of Oil Hydrogenation," by E. J. Lush, M.A.

Feb. 6. THE INSTITUTE OF PHYSICS, Chemical Society's Rooms, Burlington House, Piccadilly, London, W. 1, at 5.30 p.m. "The Physicist in Metallurgy," by C. H. Desch, F.R.S.

Feb. 6. SOCIETY OF PUBLIC ANALYSTS. Annual General Meeting, Chemical Society's Rooms, Burlington House, W., at 8 p.m. "Osmium Tetroxide as a Reagent for the Estimation of Tannins and their Derivatives," by C. A. Mitchell; "The Composition and Examination of Beef and Malt Wine," by G. D. Elsdon, B.Sc.; An Apparatus for Fat Extraction and Solvent Recovery will be demonstrated by S. A. de Lacy. Informal Dinner will be held at 6.30 p.m., at St. James's Restaurant, 178, Piccadilly, W. 1.

Feb. 7. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, The Chemical Department, The University, Bristol, at 7.30 p.m. Meeting held under the scheme of co-operation with the Chemical Society. "Current Chemical Research at Bristol University," by Profs. F. Francis and J. W. McBain.

Feb. 7. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1, at 8 p.m. "The Solubility of the Aminophenols," and "Abnormal Benzene Derivatives," by N. V. Sidgwick and R. K. Callow.

Feb. 7. ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 5.15 p.m. "Crystalline Structure of Organic Substances," by Prof. Sir W. Bragg. Also on February 14, 21 and 28.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL MEETING

A meeting was held on January 28 in the Town Hall, Liverpool, to make arrangements for the Annual Meeting of the Society, which is to be held in Liverpool in July.

The Rt. Hon. the Lord Mayor of Liverpool, Mr. Arnold Rushton, J.P., said it gave him particular pleasure to preside over the meeting. The Society of Chemical Industry was formed in 1881, largely through the zeal and enterprise of local chemical manufacturers, one of the pioneers of the work being the late Dr. E. K. Muspratt, the great friend of Liverpool: he did great work for the City, and was very prominent in the formation of this Society. I understand that among your other notable members were Dr. Mond, Mr. Eustace Carey, Mr. John Gray, and to-day we are fortunate that Lancashire also provides the present President, whom we are delighted to see here, Dr. E. F. Armstrong, of Warrington. Your Society has progressed very much in the last forty years and now has 5000 members, with eighteen branches spread over the United Kingdom, Australia, Canada and the United States, and in 1907 you were incorporated by Royal Charter, so that you have gone along very famously indeed. It is customary to hold the Congress in one or other of the leading cities of this country, and this is the fifth occasion that Liverpool has been favoured. You know as well as I do what the objects of your particular Congress will be, and of course it will include the bringing together of all those who are interested in Chemistry as an industry, the reading of technical papers, social intercourse and everything good for the Society of Chemical Industry and its members. I can assure you that in addition it will have the co-operation of the civic authorities, and the Lord Mayor particularly will do everything possible to make it a success. You require, also, the co-operation of other societies and other branches of industry in this great city. Mr. Sandeman Allen, the Chairman of the Chamber of Commerce, regrets very much that he is unable to be with us, but sends a message saying they are only too anxious to do everything they can to enhance the success of the Congress. We want, also, the representatives of our University, and I am sure they will co-operate, also other sections of the business community. I think from what I have heard that everything points to a most successful Congress. I have much pleasure in calling on the President to give us a statement and possibly to move a resolution.

Dr. E. F. Armstrong then said: After the very illuminating statement we have heard about the past of our Society, it needs but few words to make the position quite clear. It is hardly necessary in Liverpool to emphasize the importance of the chemical industry to shipping and all that it means: the chemical industry is the most important one on Merseyside. Our Society, the Society of Chemical Industry, caters for those engaged in the chemical industry in the very widest sense. Our membership is open to directors, commercial as well as technical,

to process managers, to the works chemists, research chemists, to the whole academic profession, consulting, and analytical chemists, and to any others who happen not to be included in the previous category. Including in our ranks all engaged in the chemical industry and in the practice and profession of chemistry, it can claim to be representative. We can also claim to be essentially democratic. Our objects and aims are simple; they are so to advance the practice and the science of chemistry as to give social service to the community; they are to advance the interests, professional and otherwise, of our individual members, to bring the latest knowledge to them by means of our publications, and, what is perhaps as important as anything, to bring them together and to get them to know one another. From that point of view our annual meetings are of particular importance, and we owe them to the invitation, year by year, of our constituent Sections. On more than one occasion we have enjoyed the hospitality of Liverpool, and it has always been memorable. At our annual meetings we have the Presidential Address, technical papers, and every opportunity for that mutual intercourse which is so important. I feel sure that our meeting in Liverpool this year has so much tradition behind it, so many famous names have been connected with the Section, that nothing can prevent this meeting being as great a success as its forerunners, and I am sure that, under the able chairmanship of Mr. Edwin Thompson (the Chairman of the Liverpool Section of the Society) it will be a success. I would like to move that the gentlemen present, and those invited but prevented from coming, be asked to form a General Committee for the purpose of initiating this meeting in July next. I do not think the duties of the General Committee will be very onerous, but it will be very valuable to have such as Committee.

Mr. John Gray seconded the resolution, and it was passed unanimously. It was then proposed by Sir Max Muspratt, Bart., and seconded by Mr. W. H. Roberts (and carried unanimously), that about forty gentlemen be asked to form the Executive Committee.

Professor I. M. Heilbron proposed that the following should be the officers of the Executive Committee: Mr. Edwin Thompson, Chairman; Mr. W. H. Roberts, Vice-Chairman; Dr. Alfred Holt, Hon. Treasurer; Mr. E. Gabriel Jones, Hon. Secretary. Prof. Bannister seconded the proposal, and it was passed unanimously.

Mr. Edwin Thompson then moved that the meeting should express a vote of thanks to the Lord Mayor for so very kindly presiding at this meeting. When this meeting was mentioned to him he at once said that he would take a great interest in it, and he very kindly offered to entertain the members when they visited Liverpool, and he threw himself wholeheartedly into it. A very cordial vote of thanks for so kindly presiding at this meeting was accordingly proposed.

Dr. G. C. Clayton, M.P., said it gave him the very greatest pleasure to second this vote of thanks to the Lord Mayor, and that he felt satisfied and confident that with the Lord Mayor's assistance it would be a very memorable gathering in Liverpool.

The Lord Mayor, in acknowledging the vote of thanks, wished the Congress all luck and every success.

OFFICIAL NOTICES

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

Vol. VIII is now in preparation and will be issued very shortly. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members. Vol. I is out of print, but copies of Vols. II, III, IV, V, VI, and VII may be obtained by members at 4s. 6d., 5s. 6d., 5s. 6d., 8s. 3d., 7s. 6d., and 7s. 6d., and by non-members at 7s. 6d., 10s. 6d., 12s. 6d., 15s., 12s. 6d., and 12s. 6d. respectively. If Vols. II, III, IV, V, VI, and VII are ordered at the same time as Vol. VIII, the set may be obtained by members for £2 2s. 6d., and by non-members for £3 15s. The appropriate remittance must accompany every order. The books are sent to purchasers post free.

AMERICAN CHEMICAL SOCIETY

The Council of the Society of Chemical Industry will be glad if any members of the Society, who expect to be in the United States in April next, will kindly act as delegates of the Society at the Annual Meeting of the American Chemical Society, which will be held in Washington, D.C., on the 21st of that month.

The General Secretary will be glad to hear from any members of the Society who can make it convenient to be present at the meeting, and he will gladly forward their names to the Secretary of the American Chemical Society.

EDITORIAL NOTICES

The Society as a body is not responsible for statements and opinions appearing in the JOURNAL.

Members of the Society, and others, are invited to submit original articles, news, notes and other relevant information to the Editor of *Chemistry & Industry*. Such contributions should be clearly written (preferably typewritten with double spacing), and be accompanied by a stamped and addressed envelope. They will be paid for if inserted. Sources of information should always be given, not necessarily for publication.

Hon. Secretaries of Local Sections and of other Societies are asked to forward notices and reports of meetings as early as possible, and publishers to send books for review, direct to:—THE EDITOR, *Chemistry & Industry*, SOCIETY OF CHEMICAL INDUSTRY, CENTRAL HOUSE, FINSBURY SQUARE, E.C. 2. [Telephone: Clerkenwell No. 2429.]

Hon. Secretaries of Local Sections and of other Societies are asked to note that announcements of forthcoming events cannot be inserted in the next issue of the JOURNAL *unless they are received not later than Tuesday in any week.*

Matters relating to the Transactions and Abstracts, including Papers intended for insertion as Communications, should be addressed to THE EDITOR OF TRANSACTIONS, at the same address.

LIVERPOOL SECTION

On January 18 a joint meeting with the Liverpool and North-Western Section of the Institute of Chemistry was held in the rooms of the Overseas League, Mr. Edwin Thompson in the chair.

Mr. S. P. Leigh gave an address on "Some Aspects of British Chemical Trade Abroad," in which he said it was sometimes useful to look at the trade in British heavy chemicals from the point of view of the consumer abroad. China is already a very big market, but its consumption per head is on a very low scale; with 350 million inhabitants a comparatively small increase in the consumption per head would add enormously to the volume of trade. Labour costs in China are remarkably low, but any large industrial expansion would undoubtedly tend to adjust these to the levels of the outside world. There are especial possibilities for the extended use of fertilisers in China. One great asset in this market is the conservatism of the Chinese buyer, who, provided an article is good, will refuse all substitutes.

In the Tropics, the ice, mineral-waters and soap industries are found universally, and all consume chemicals. From China to Burma, the Chinaman is the master of the soap industry. He manufactures on a very small scale and displays a genius in keeping low his manufacturing costs. The soap works are sometimes built almost entirely of caustic-soda drums, which gives an added importance to the always vital matter of packages.

During the war, the heavy chemical market in Java was captured by Japan and the United States, but we have subsequently recovered the bulk of our share of this business, partly owing to the varying quality of Japanese goods.

In South America, the United States was the chief supplier during the war. We have since largely recovered our position, and we have more now to fear from German than from American competition. The Germans still have large funds available for overseas trade expansion, and are already exploiting them on a large scale. Having lost their Colonies, and with their immigration to the United States strictly limited, South America is the only suitable outlet for their surplus population. The inevitable increase of the numbers of Germans in South America which will thus result during the next few years will have a most important influence on the trend of business in these markets, and we shall have to use our utmost efforts, backed by our existing goodwill, and our large capital investments, if we are to maintain our position.

In India, among many possibilities, there are two which stand out as offering opportunities for an enormous expansion in chemical business in that market in the future. The first is the disinfection, by chloride of lime or liquid chlorine, of the rivers, particularly the Ganges, in which the sacred bathings of the Hindus are performed. These, at the present time, play a great part in the spread of infectious disease. The second is the increased use of fertilisers. The yield per acre of many crops in India is very low, and the soil undoubtedly requires added plant food. Before this can be generally adopted, however, the Indian Government will have to find some means of freeing the farmer from the tyranny of the money-lender, to whom he usually has to pay all his available means.

In Australia the rapidly increasing complexity of social and industrial life has resulted in a widening of the scope of demand for chemicals, but for many years the main outlet for these products will be found in the great primary agricultural industries.

The part which British industry played in the victory of the Allies in the great war is fully appreciated by our customers throughout the world, and has resulted in the enhanced prestige of British industry and British products, which we must maintain by every means in our power.

NOTTINGHAM SECTION

At the meeting held on January 23, two papers were read on "The Microscope as an Aid to Analysis." The chair was taken by Mr. H. Droop Richmond. In the first paper Mr. Woodhouse described investigations carried out at the Stanton Iron Works, and gave an account of the microscope as an aid in determining factors which cannot always be arrived at by the use of analysis alone. The process of preparing samples of iron for microscopical examination was first outlined, followed by results of typical examinations of various manufactures of iron. An excellent set of microphotographs was shown, illustrating the various differences in the crystalline structure of the above substances. Chemical analysis often showed an apparently abnormal value, say, for phosphorus or silicon, but a microscopical examination would often save much time in confirming the chemical result, thus saving a more tedious second analysis. The physical structure of "chilled iron" and "white iron" was practically the same, yet the microscope clearly showed that there was a definite difference between the two, and a brief discussion of the equilibrium diagram of the iron-carbon system during cooling indicated the cause of this difference.

Mr. R. W. Sutton, B.Sc., A.I.C., read a paper by Mr. S. R. Trotman, M.A., F.I.C., on the same subject, with particular reference to the use of the microscope by the practising chemist. Metallurgical and research chemists made use of the microscope chiefly for the specific examination of the structure of metals and alloys, and for the classification of crystals, whereas the chemist in practice depended upon microscopical examination for elucidating a great variety of technical problems, *e.g.*, the quantitative determination of (1) fat in milk, or of fatty acids in soap; (2) foreign ingredients in foodstuffs and food accessories; (3) constituents of mixtures of unknown origin and constitution; qualitative examination and identification of (4) minute amounts of substances such as the causes of discolorations and damage in textiles; (5) substances separated during the course of analysis, such as crystals obtained from a trace of alkaloid. In most of these problems as in a host of others, constant use was made of the microscope—perhaps with the polariser—but with very little apparatus, although macerating agents, selective

stains and chemicals were required. As examples, the detection of the adulteration of ground oats and sumach was described.

Instances were cited in which supplementary microscopical examination greatly assisted chemical examination. Thus the detection and identification of adulterants in foodstuffs such as chicory in coffee, and husks in cocoa, were made very much easier by use of the microscope. The solving of problems connected with textile materials would be impossible without microscopical examination, and slides were shown, illustrating how cotton fibres, of which the cuticle was destroyed, developed characteristic globular swellings when treated with Schweitzer reagent.

In the subsequent discussion Mr. Adams emphasised the importance of the microscope in the engineering works, and observed that microscopical examination of a steel practically gave its autobiography. As an example, where chemical examination revealed nothing, he mentioned the elongation of an axle, which microscopical examination showed had been caused by heating, followed by quenching. In the railway service the cause of failure in metals such as copper, white or bearing metals, was clearly shown by the microscope, which is indispensable in any engineering laboratory. Mr. Pentecost referred to stains in fabrics, such as silk taffeta, the cause of which could not be traced chemically. Examination under the microscope, however, revealed that the "stain" was an optical effect, due to fracture of silk fibres. The only way to avoid such damage was to prevent friction during any part of the process.

Mr. Meek explained a recent application of the microscope to detect the appearance and disappearance of certain alkaloids during growth of plants such as the opium poppy. Mr. Wood referred to the use of the microscope in leather manufacture. Miss Wright spoke of the use of the microscope in the examination of paints and pigments, and Mr. Rome outlined the use of the microscope in water analysis.

The Chairman then touched upon some of the uses of the microscope not referred to in the papers. It was a simple matter to ascertain immediately by microscopical examination the source of a sample of kieselguhr and its suitability for various uses such as a filtering material. The detection of crime by microscopical examination of bloodstains was another aspect; also examination of dust in clothes often gave valuable information as to its origin.

GLASGOW SECTION

A joint meeting with the local section of the Institute of Chemistry was held on January 25, in the Institute of Engineers and Shipbuilders, Glasgow, Mr. J. H. Young in the chair. An interesting address, with lantern illustrations was delivered by Mr. F. W. Harris, F.I.C., of the Glasgow Corporation, on "Modern Methods of Sewage Purification."

In introducing the subject a historical survey was given with special reference to the progress made with the sewage purification and disposal schemes of Glasgow. The Glasgow sewage was first treated, for example, at the Dalmarnock works, with precipitants such as sulphate of alumina and lime and thereafter allowed to settle in septic tanks. The clear sewage from the tanks was then passed through filters composed of pieces of whinstone of varying size, and finally discharged into the river Clyde. A full account was given of the biological filtration systems and of the methods of bio-aeration. The experimental activated-sludge plant installed at the Shieldhall works was described in detail and the methods adopted in sewage purification to speed up the oxidation of the organic matter were discussed in relation to the activities of the protozoa and other organisms.

After an adjournment for refreshments, a very full discussion took place. References were made to the difficulties encountered through the introduction of wastes from various factories and to the necessity for regulations to control the nature of these wastes. The question of the disposal of the sludge and its fertilising value was mentioned. The "activated sludge" had a superior value but there were great difficulties involved in its use owing to its high moisture content. Unfortunately the physical condition of the material greatly altered when it was dried.

Mr. Harris was cordially thanked for his paper and it was announced that an invitation had been extended to members of the sections to visit the Sewage Purification Works of the Glasgow Corporation.

BRISTOL SECTION

At the recent meeting of the above Section, Mr. Osman Jones, of Messrs. Harris', of Calne, read a paper on "The Chemical Technology of Canned Foods." After touching upon the purposes of canning, Mr. Jones confined his remarks chiefly to the technology of canned meats.

The safety of canned goods was emphasised and illustrated by the fact that, in spite of the enormous number of canned rations issued during the war, complaints due to spoilage were practically unknown. After describing the equipment of the canning factory and the high state of cleanliness maintained, the can itself was dealt with, particularly the methods of testing the tinplate used, and the methods for hermetically sealing the cans. In one important type of can, now much used, the contents did not come into contact with a soldered joint. Apart from the selection of good raw material, the vital need was shown for ensuring sterile conditions during filling and processing the material. The elaborate methods for testing the finished article and for preventing spoilation due to bacteria, were treated very fully.

The paper led to an excellent discussion, and a hearty vote of thanks was accorded to the speaker.

On January 23, members and associates visited the Brislington Factory of Messrs. Jas. Robertson and Sons, Ltd., Preserve Manufacturers. The party was shown the various plant and processes for the

manufacture of Golden Shred Marmalade, which was seen to consist only of the juice and shredded outer skin of oranges, together with white sugar. Mr. Robertson personally explained the processes and afterwards entertained the party to tea. A hearty vote of thanks to the Directors and Members of the staff for their courtesy and kindness was proposed by Mr. Jones, and seconded by Mr. Boorne.

The Annual Dinner of the Section will be held jointly with the Institute of Chemistry, at the Royal Hotel, College Green, Bristol, on Saturday, February 16. The President of the Society and other distinguished chemists hope to be present.

MIDLAND VARNISH AND PAINT MANUFACTURERS' ASSOCIATION

The fifth annual dinner took place on January 17, at the Queen's Hotel, Birmingham, Mr. S. K. Thornley presiding. The Council of the National Federation of Associated Varnish, Paint and Colour Manufacturers' Associations had held a meeting in Birmingham on the same day, and nineteen members, including the President, Mr. Mark Harrison, were the guests of the Midland body. In recognition of his long and valued services to the Midland Association a silver rose bowl was presented on behalf of the members to Mr. Thornley by Mr. Lloyd Matthison (this year's President), who pointed out that Mr. Thornley had also filled the office of President of the National Association and had been chairman of the Joint Industrial Council for the Varnish and Paint Industry.

Replying to the toast of the "City and Industries of Birmingham" (proposed by Mr. J. J. Gittings), the Lord Mayor said he was optimistic regarding the future of Midland trade; it was certainly improving.

Mr. P. M. Sturge, submitting the toast, "The National Association," referred to its work in various phases, especially mentioning the industrial classes connected with the varnish, paint and colour trades, which were held at the Birmingham Central Technical School. These classes were held in the evening, were well attended, and were proving of great value. Scientific and technical education was essential if British industry were to compete successfully with other industrial nations in the international markets.

Mr. Mark Harrison, in response, alluded with satisfaction to the happy relationship existing between employers and employed in the varnish, paint and colour industry. In recent years it had been almost alone in its freedom from strikes, threats of strikes, and serious labour troubles. Employers and workers, he said, had met each other in a fair and generous manner.

Mr. Gilbert Vyle, President of the Birmingham Chamber of Commerce, replying to the toast "Our Guests," proposed by the chairman, stated that the trade of applied paint, varnish and colour had altered little in the way it was conducted, the only exception being, perhaps, in a few industrial processes in which they had speeded up the method of application. Protection was the oldest law in nature, and the Varnish, Paint and Colour Manufacturers' Association was amongst the greatest protectionists, because it stood between us and decay, red rust and dissolution.

CORRESPONDENCE

SILICA GEL

SIR,—In your issue of December 7, Mr. J. Arthur Reavell takes exception to my statement that drying of gases is "a pre-requisite" of the employment of silica gel in solvent recovery operations, for the simple reason that commercial installations for the recovery of benzol from coke-oven gases are now in operation without any attempt being made to dry the gases.

I should like to point out that this alleged discrepancy between fact and statement is more apparent than real. Mr. Reavell will not deny that silica gel is an excellent dehydrating agent. May I ask how gases are to be passed through a silica-gel absorber without being dried in the process? It is wholly immaterial whether a separate drier containing silica gel (or other dehydrating agent) is employed prior to the benzol absorption tower, or whether a portion of the silica gel in the absorption tower itself is the means of removing the water. The fact is that if the gases are not dried previously, *a definite portion of the absorbent gel must be allocated to the absorption of water.* Such water absorption occurs in the first portion of the absorber, and the benzol is taken up by the residual gel capacity remaining available. For all practical purposes my original statement stands, but I am quite content to broaden it by substituting the word "requisite" for "pre-requisite."

The quantitative effect of the presence of water vapour upon the over-all efficiency of silica gel, in comparison with high-grade gas absorbing carbon has been dealt with in our published experimental data, referred to in my letter of November 23; and need not be reviewed here. These comparisons were based upon samples purchased by us at $3.00 per lb. from the Silica Gel Corporation in the United States. It was particularly specified that the samples should be suitable for "benzol absorption." We should be very interested if Mr. Reavell would inform us whether the absorption capacities reported by us upon these samples show them to be materially inferior to the gels used in the English installations of which he speaks. If not, the conclusion is inevitable that the recovery of benzol from coke-oven gases is commercially practicable with solid absorbents of a relatively low absorptive capacity in comparison with the standards required of gas absorbent carbons now manufactured for the recovery of gasoline from natural gas. However, I do not wish to be misunderstood as saying that absorptive capacity is the sole technical consideration in choosing an absorbent material, or that certain processes may not be worked out in which other properties of silica gel would compensate for its inferior absorptive capacity.

When Mr. Reavell speaks of activated carbons having been in use for so many years without substantial progress, he falls into a common error which is the fault of the nomenclature in use. Activated gas absorbent carbons of the types we are now discussing originated with silica gel during

war investigations and are an equally distinct technical novelty. If the kakologophobia of our pseudo-Parisian commentator upon the idiosyncrasies of "English As She Is Spoke," should cause the discovery or suggestion of some word of real distinction and beauty to replace the phrase "activated carbon," which now means all things to all men, he would be the recipient of much gratitude.

I should like to take this opportunity to express my appreciation of the extremely courteous and fair restatement of his position on this subject made by Mr. Rex Furness in your issue of November 30. The object of my letter was to protest a prejudgment of the issues between the two absorbents, not myself to prejudge them: also to clarify subsequent discussions by emphasising the fact that silica gel and carbon adsorbents are not alike but fundamentally different and that nothing but confusion can result from assuming a relationship which does not exist. The technical problems associated with their industrial development are materially different and each will have to stand upon its own feet. In view of these differences it seems unlikely that both absorbents will continue indefinitely to occupy closely related fields but rather that their typical applications will become more and more divergent.—Yours faithfully,

N. K. Chaney

Union Carbide and Carbon Research Laboratories, Inc.

SMOKELESS FUEL

Sir,—If you will kindly allow me the space, I will do my best to answer "Vulcanus's" questions in your issue of the 18th. inst., though I may be unable to emulate his exalted style. Of course I cannot tell what Mrs. Editor's remarks on the subject may have been, and all I can do is to try and tabulate what may be a housewife's objections and present them in the question-and-answer form.

Is "Coalite" easy to light?

Yes, quite, and it requires no attention, and burns to the last atom.

Is there much ash to remove?

Very little, and the grate requires less cleaning, and chimney-sweeping is avoided.

How about dirt?

There is no dirt; there may be a little fine ash, but that is quite clean and excellent for keeping moths out of carpets and such things.

Is there any special trouble about it?

No, but reduce the draught as much as possible, so as to get full benefit of the radiant heat, and then you will find that a ton of "Coalite" goes as far and gives as much heat as two tons of the very best domestic coal, which costs the same per ton.

Now for "Vulcanus's" own questions.

You can get "Coalite" from Messrs. Hoare Gothard and Bond, Ltd., but supplies at present are not what they should be; still, supplies ought to increase rapidly from the end of February onwards.

"Coalite" is suitable in all cases where Welsh steam coal, anthracite, or any class of bituminous coal can be employed; the draught must be damped down as soon as fuel is well alight, so as to get full advantage of the intense radiant heat.

On the subject of boiling water, perhaps the best reply is a paragraph from Professor Smith's report on a test carried out between "Coalite" and the very best Welsh steam coal.

"The results are eminently satisfactory. From lighting the fires all cold, full steaming was obtained in half the time with 'Coalite' as with coal. While, after banking-up, vigorous steaming occurred in 7 minutes with 'Coalite,' as against 25 minutes with coal. Indeed, although the 'Coalite' 'bank-up' lasts two hours as against 1¾ hours only with coal, steaming ceased entirely before the end of this period with coal, while it continued freely all the time with 'Coalite.' During the banked-up period the average steaming was 44 per cent. greater with 'Coalite' than with coal, the fires having equal depths and being in equally good condition at the beginning of the "bank-up.'"

N.B.—Low-temperature carbonisation is the only method, barring water-power, by which electrical supply can be produced cheaply.—Yours faithfully,

F. A. Wilson

London

Jan. 23, 1924

A QUERY

Sir,—I have reached a stage in some experiments I am doing where I am held up, and wish you would assist me. I require a substance which will burn with a luminous flame, after the fashion of magnesium, and also (if a solid) a solvent for same, which will deposit it unchanged on evaporation. Magnesium will do perfectly if you can recommend a suitable solvent. Trusting that I have made my requirements clear, and that you will be able to help me, I thank you, and remain, yours sincerely,

John R. Charlt[illegible]

Gloucester

CARBON MONOXIDE HAZARDS FROM TOBACCO SMOKE

Tests were made to determine (a) the amount of carbon monoxide present in a non-ventilated room in which tobacco smoke was liberated by smoking, and (b) the extent to which it was absorbed by the smokers. The percentage of carbon monoxide present was never greater than 0·02 per cent., and the percentage of carbon monoxide saturation of the blood was not greater than 5 per cent. Tests made to determine why a smoker does not absorb more carbon monoxide into his blood, showed that concentrated smoke does not reach the alveoli of the lungs, and that the maximum average concentration of carbon monoxide drawn into the lungs would not be greater than about 0·01 per cent.—(*J. Ind. Hyg.*, *Jan.*, 1924.)

PERSONAL AND OTHER NOTES

The Society of Chemical Industry has decided to confer the Messel Medal this year upon the Rt. Hon. Viscount Leverhulme. Lord Leverhulme has for very many years been a dominant figure in a great industry which has important chemical connexions; his wide outlook on social questions and his singular grip on the essential factors regulating the relations of the workers to the industry in which they are engaged are well known. He has for some considerable time been interested in the work of the Society, and his letter to this *Journal*, wishing it success at the moment the change was decided upon, will be fresh in the minds of our readers. Lord Leverhulme has taken an active part in many schemes of co-partnership, thrift, hygiene and social welfare, and has been the President of a number of organisations dealing with these subjects. He will deliver the Messel Lecture in Liverpool next July, and this occasion will no doubt provide him with an opportunity of expressing those pithy and shrewd observations which have in the past delighted his audiences, and are only possible to a man with great knowledge of human nature and experience in many branches of activity. Lord Leverhulme's career has been a romance as well as a success, and in spite of the immense amount of work he achieves he has found time to interest himself in art, in politics, and in the scientific work of the industry in which he and his many companies are engaged.

Dr. J. N. Greenwood, of Sheffield, has been appointed professor of metallurgy at the University of Melbourne.

Dr. R. H. Clark, of the Department of Chemistry, University of British Columbia, is the new Hon. Secretary of the Canadian Pacific Section of the Society of Chemical Industry.

Mr. J. C. Pearce has been appointed Director of Research to the British Cast-Iron Research Association in succession to Dr. P. Longmuir, who has had to retire on account of ill-health. Mr. J. E. Fletcher has been appointed consultant to the Association.

According to *The Times*, Prof. Niels Bohr has received $40,000 (about £8000) from the Rockefeller International Education Board, which "he may use to modernise his laboratory and to buy new instruments."

* * *

The death is reported of Prof. R. R. Thompson, O.B.E., M.Sc., professor of oil technology at Birmingham University. Prof. Thompson, who was about 0 years of age, had recently been appointed adviser to the British West Indian Petroleum Syndicate.

It is with deep regret that we have to announce the sudden death of Mr. A. C. Flint, who has been Assistant Secretary of the Chemical Engineering Group since soon after its inception. He also acted as assistant secretary of the Institution of Chemical Engineers durng its formation, and up to the present. The members of both these organisations have the highest appreciation of the work he has done and his loss will be most grievously felt. He leaves a wife and two children.

UNITED STATES

The Patent Office

The number of applications for patents which still await examination has been reduced from 74,256 on September 21 to 65,010 on December 21. Similar reductions have been made in the number of applications for designs and trade marks, so that applications for patents now pass through in nine months instead of fifteen, designs in ten weeks instead of eight months, and trade marks applications in seven weeks instead of five months.—(*Chem. and Met. Eng.*, *Jan.* 14, 1924.)

Fuller's Earth in 1922

The output of fuller's earth in the United States reached its highest point in 1922, the production by 15 operators totalling 138,944 short tons, worth $2,289,719, an increase in quantity and value of 32 per cent, and 16 per cent, respectively, compared with 1921. Occurrences of fuller's earth are found in many States, but during 1922 only eight States were producing, Florida retaining its position as the chief producing State. Imports increased by 8 per cent, to 10,569 t., thus making the apparent consumption 149,513 t.

GERMANY

The German Chemical Society

A note in the current number of the *Chemisch Weekblad* (Jan. 19, 1924) states that a member of the Dutch Chemical Society resident in America has sent the following letter to the German Chemical Society :—

"I am in receipt of your request for subscription remittance for the year 1924. From it I see that you assume the right to ask for additional subscription if costs of printing would further increase. I cannot help but feel that your attitude is absolutely wrong.

"First of all, a membership of a society is an agreement with a mutual character. If you assume a right there should be also a right on the side of the members, that is, that the subscription should be decreased in case cost of printing decreases. Moreover, the increase in the membership fees should be limited to a certain amount, whereas according to your circular they are unlimited.

"Furthermore, I think it absolutely wrong to bring up the question of rights in this connexion. This is just another slip of the German mind, and it seems very hard for you as a nation to learn. If you get into trouble without your fault you should not trust to rights. Has the famous expression 'a scrap of paper' not been found out by your countrymen? Better to trust to friendship and good relations and that they will, if you deserve it, help you through your difficulties. I had no objections to sending you $3.00 a few days ago, because you requested assistance of your foreign members in order to get through your troubles. Since you bring up the point of having a right to do so, the best attitude for me and I hope for many others will be to leave you alone.

"For the above mentioned reasons I do not want to take a subscription to your publications for the

next year. I am just sending you the membership fee amounting to $2.00, and if you do not change your attitude I would remind you of the fact that the abstracts of the American Chemical Society at present are certainly as excellent as the abstracts of the German Chemical Society and, in addition, are printed much better, which, of course, is a great attraction. I know that conditions make it impossible for you to use similar paper and type, but circumstances such as this should certainly make you very careful in bringing up the question of 'rights' where apparently no rights exist and some modesty could be well applied."

Explosion at Merseburg

The Times reports that, on January 24, a violent explosion, recalling that at Oppau in 1921 (*cf. J.*, 1921, 381 R), occurred at the Leuna works, near Merseburg, 15 workmen being killed, a number injured, and various buildings wrecked. The cause of the disaster is not stated, but it is said that a high-pressure container blew up in the department devoted to the manufacture of ammonia products.

GENERAL

Kelvin Centenary

As the centenary of Lord Kelvin's birth will occur on June 26, the Royal Society has convened a committee, under the presidency of Sir Richard Glazebrook, F.R.S., and including representatives of the societies devoted to the promotion of physical science, to make arrangements to celebrate the occasion in a fitting manner. Many British and foreign scientists and engineers will be attending conferences at the British Empire Exhibition at that time, and so July 10 and 11 have been selected for the Kelvin centenary celebrations. There will be a memorial address by Sir J. J. Thomson at a meeting for the reception of addresses from delegates, a dinner presided over by Lord Balfour, and, it is hoped, a reception by the Royal Society at Burlington House. There will also be an exhibition of apparatus and, if possible, a memorial volume will be issued.

The World Power Conference

This conference, organised by the British Electrical and Allied Manufacturers' Association, in co-operation with various technical, scientific and industrial bodies, both British and foreign, will be held at the British Empire Exhibition from June 30 to July 12. Classified into divisions, comprising power resources (I), production (II), transmission and distribution (III), utilisation (IV), and general economics (V), the conference will provide much of interest to the chemist, as special sections are devoted to the preparation of fuels and their utilisation, as well as to electrochemistry and electrometallurgy. The Secretary of the Chemistry and Physics Section is Mr. H. Talbot, B.Sc. (representing the Chemical Engineering Group), and Mr. S. S. Ogilvie, B.A., is Secretary of the Gas and Fuel Section. The fee for membership of the Conference is £2, which entitles the applicant to free admission to the British Empire Exhibition and the Conference Halls during the Conference. Further information can be obtained from the Secretary, World Power Conference, 36 Kingsway, London, W.C. 2.

REVIEW

COAL TAR DISTILLATION AND WORKING-UP OF TAR PRODUCTS. By ARTHUR R. WARNES. *Third edition, rewritten and enlarged. Pp. xv+511. London: Ernest Benn, Limited,* 1923. *Price* 45*s*.

The writer regrets that he is unable to agree with the author that the additional chapters added to the third edition are an improvement, for he is disappointed to find that the very excellent matter of the first edition appears to be nearly obscured by the additions and elaborations of the third.

At the same time, to the industrious reader, the book is a very rich mine of information, from which, with more or less labour, some very valuable and practical ideas on the art of distilling tar may be extracted. This, of course, is inevitable, as Mr. Warnes' long experience in the tar industry has given him opportunities of collecting data and making observations which he has not neglected, and if, when he comes to write another edition, he will exercise a judicious pruning knife and rearrange the beds and borders of his garden, we may look forward, at last, to having a book, written by a native of that England where tar distillation had its origin, of which we may be entirely proud.

If the author will permit him to do so, the writer would like to make a few suggestions as to the direction in which improvements might be made. He would suggest that the chapters on the geology and botany of coal hardly concern the practical tar distiller, neither does that on stripping gas, though the latter is perhaps a little more cognate to the subject; he would therefore plead for their curtailment, if not entire deletion. Then, again, he feels that the book would be read more easily if the order in which the various subjects are arranged were made to take some more logical sequence, and not jump as it does from the distillation of tar to the extraction of carbolic acid, then to benzol and pyridine, back to naphthalene and anthracene, and to pitch, finally ending with creosote.

The excellent 100 pages devoted to tarworks' tests is somewhat unevenly distributed, and 25 per cent. of the total seems a good deal to allot to the highly important, but still single, subject of the determination of benzene, toluene, etc. in mixtures.

In the next edition, which it is earnestly to be hoped will appear without undue delay, it would perhaps be better to give a little more attention to proof reading, and so avoid some ambiguities and an occasional error; for example, it is usual to write C_nH_{2n+2} etc. as the general formula of the various series, and not $C_nH_{2n}+2$, as appears in the present edition.

The writer has expressed his views very frankly, because he feels that Mr. Warnes has not given himself time to do entire justice to his subject and to himself, and that with a very little greater expenditure of time and thought he could have done so very much better.

W. H. COLEMAN

'ARLIAMENTARY NEW

HOUSE OF COMMONS

Imports of Dyestuffs

In reply to Lieut.-Com. Kenworthy, Viscount Wolmer gave the following statistics of dyestuffs imported during 1923 :—

	Cwts.	£
Dyes and dyestuffs (except dye woods and raw dyeing substances) and extracts for dyeing and tanning :—		
Intermediate coal-tar products used in the manufacture of dyes (including aniline oil and salt, and phenylglycine)	1,349	17,010
Finished dyestuffs obtained from coal tar :—		
Alizarine	8,409	72,761
Indigo, synthetic	8,274	13,243
Other sorts	39,474	917,721
Extracts for dyeing :—		
Cutch	48,395	69,475
All other sorts	72,904	310,852
Indigo natural	757	26,915

—(Jan. 22)

Adjournment

The House has adjourned until February 12.

COMPANY NEWS

BENZOL & BY-PRODUCTS, LTD.

At the fourth annual meeting the chairman, Sir H. D. Bax-Ironside, said that the profits of working for the last 18 months were £47,934, after deducting charges and adding to reserves. Preference dividend had absorbed £7920, and the balance of £40,013 had been carried forward (the preceding accounts showed a loss of £44,500). Fixed assets totalled £315,778, compared with £419,846, £18,888 having been written off as depreciation and £89,918 provided by reducing the capital. Trading since last September showed a progressive increase. The tar distillery was, for the first time, almost working at capacity, there was an increased output at the colliery, and a shaft was to be widened. The company's by-products were well sold for several months ahead. It was proposed to pay, at an early date, an interim dividend on the preference shares in excess of the fixed half-yearly dividend of 3 per cent. The report and accounts were adopted.

NICKEL CORPORATION

The accounts for the year ended March 31, 1923, show a loss of £1,981, which has been transferred to the International Nickel Co., Ltd.

COMMERCIAL GAS CO.

Dividends for the 6 months ended December 31, are recommended at the rates of £6 per cent. per annum on the 4 per cent. and on the $3\frac{1}{2}$ per cent. stocks. These compare with £5 16s. and £5 15s. per cent., respectively for the previous year.

...IDLAND BANK, LTD.

At the ordinary general meeting on January 25, the Chairman, the Right Hon. R. McKenna, reviewed the economic situation, and showed how the amount of money in existence varied with the amount of deposits in the banks. He then explained the difference between a legitimate increase in the amount of money and inflation. Unproductive borrowing led to inflation, but a loan to increase production was self-liquidating, provided the repayment of past loans balanced the extension of new ones. Indications were that we were nearing the end of a trying period, although full peace had not yet been restored, and he looked forward with confidence to the future.

An account of the financial situation of the Midland Bank has already appeared in the issue of *Chemistry and Industry* dated January 11 (p. 52).

ENGLISH CHINA CLAYS, LTD.

Dividend on preference shares is announced to be 7 per cent. per annum for the half-year ended December 31, 1923.

SOUTH METROPOLITAN GAS CO, LTD.

The directors recommend a dividend of $5\frac{3}{4}$ per cent. for the year 1923, carrying forward £254,510, compared with a dividend of $5\frac{1}{2}$ per cent. and a carry-forward of £236,400 for 1922.

GAS LIGHT & COKE CO., LTD.

Subject to audit of the accounts, it is proposed to pay dividends of £4 per cent. on the 4 per cent. consolidated preference stock, £3 10s. on the $3\frac{1}{2}$ per cent. maximum stock, and £5 6s. 8d. on the ordinary stock. The carry-forward is £227,295.

EXTINCTION OF MINE FIRES BY LIQUID CARBON DIOXIDE

Mr. C. L. Jones, Industrial Fellow of the Mellon Institute, has sent a reprint of a paper describing experiments on the extinction of coal-mine fires by means of liquefied carbon dioxide. The method has been tried before, but with results varying from success to failure. In the experiments described, carbon dioxide from cylinders was discharged into the mine, the area on fire having been isolated by brick stoppings. The effect of the carbon dioxide is to prevent inward leakage of air, so that if each pound of gas so introduced prevented the entry of an equivalent volume of air, the generation of roughly 600 B.Th.U. is prevented. After all flame was extinguished, water was used to enable the mine to be opened without delay. The results of the experiments show that carbon dioxide should be used where the fire can be sufficiently restricted by stopping, so that prohibitive amounts of gas are not consumed. Further, with the use of the gas, a saving is effected, because the mine can be opened more quickly, depreciation of the mine due to roof-falls, etc., is decreased, and less coal is wasted.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The comparatively healthy state of the Chemical market continues, and business is very steady with few outstanding features attracting attention. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5½d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

The demand for rubber chemicals remains somewhat slow, and values are slightly lower.

Antimony Sulphide—	
Golden	5½d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide	4s. per lb.
Carbon Bisulphide	£24—£26 10s. per ton according to quantity.
Carbon Black	Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 8½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4d.—6½d. per lb. Fairly brisk demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade and there appears a more healthy prospect in the charcoal market.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. " " 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Dull market.
Solvent	5s. 6d. per gall. 40% O.P. Dull market.
Wood Tar	£5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead	£42 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—	
Crystals	8½d. per lb. Some business passing at lower prices.
Crude 60's	2s.—2s. 3d. per gall. Little business passing. Market weaker in sympathy with crystals.
Acid Cresylic, 97/99	1s. 11d.—2s. 2d. per gall. Steady business.
Pale 95%	1s. 10d.—2s. 1d. per gall. Good demand.
Dark	1s. 7d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9d.—10d. per gall. Very quiet.
Unstrained	8d.—9d. per gall.
Benzole—	
Crude 65's	8d.—10d. per gall. ex works in tank wagons.
Standard Motor	1s. 1d.—1s. 2d. per gall. ex works in tank wagons.

Benzole, Pure .. .. 1s. 4½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 3d.—1s. 4d. per gall.
Pure .. .. 1s. 8d.—1s. 10d. per gall.
Xylol .. .. 2s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 1½d. per gall. Firm. Fair business passing.
Middle Oil .. } 9d.—10d. per gall. according to grade and district. Market very firm. Demand good.
Heavy .. ..
Standard Specification
Naphtha—
Solvent 90/160 .. 1s. 0½d.—1s. 2d. per gall. } rather more business.
Solvent 90/190 .. 1s. 1d.—1s. 3d. per gall.
Naphthalene Crude—
Drained Creosote Salts £7 10s.—£8 per ton. Demand maintained.
Whizzed or hot pressed £10—£14 per ton. Quiet and weak.
Naphthalene—
Crystals .. .. £18 per ton.
Flaked .. .. £18 per ton.
Pitch, medium soft .. 85s.—90s. per ton. Nominal. No sellers.
Pyridine—90/140 .. 16s.—17s. per gall. More stable with fair business.
Heavy .. .. 11s.—12s. Firmer with better demand.

INTERMEDIATES AND DYES

Business in dyestuffs has improved appreciably since the holidays. Prices are very firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. 4s. 6d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 6d. per lb. Better demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 8½d. per lb. naked at works.
Aniline Salts .. .. 9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl [illegible]% .. 1s. 3d. per lb.
p-Chlorphenol .. 4s. 3d. per lb. d/d.
p-Chloraniline .. 3s. per lb. 100% basis.
o-Cresol 29/31° C. .. 5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Market quiet.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Market quiet.
Dichloraniline .. .. 2s. 2d. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £82 per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 3d. per lb. d/d.
Monochlorbenzol .. £63 per ton.
β Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 5d. per lb. d/d.
β Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 5d. per lb. d/d.
Nitrobenzene .. .. 5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. .. 11½d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol .. 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 6d. per lb. d/d.
p-Phenylene Diamine .. 10s. 6d. per lb. 100% basis d/d.
R. Salt .. .. 3s. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 7d. per lb. 100% basis d/d.
o-Toluidine .. .. 7d.—8d. per lb.
p-Toluidine .. .. 3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine .. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is stagnant as buyers are holding off in view of the great uncertainty as to the future of pharmaceutical chemicals.

Acid, Acetic 80% B.P. .. £50 per ton.
Acid, Acetyl Salicylic .. 3s. 6d.—3s. 10d. per lb. Steady demand.
Acid, Benzoic .. .. Commercial acid dearer at 2s. 9d. per lb. B.P. quality remains unobtainable.
Acid, Boric B.P. .. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric.. .. 18s.—20s. per lb.
Acid, Citric .. .. 1s. 5½d. per lb., less 5% for ton lots. Demand fair.
Acid, Gallic .. .. 3s. per lb. for pure crystal. More inquiry.
Acid, Pyrogallic, Cryst... 6s. per lb., for 28 lb. lots.
Acid, Salicylic .. .. 2s. 4d.—2s. 6d. per lb. Market weaker.
Acid, Tannic .. .. 3s. 3d. per lb. for B.P. quality.
Acid, Tartaric .. .. 1s. 1½d. per lb. less 5%. Fair demand.
Amidol .. .. 9s. per lb. d/d.
Acetanilide .. .. Declined to 3s. per lb., but supplies still short.
Amidopyrin .. .. 14s. per lb. Demand negligible.
Ammon. Benzoate .. 3s. 9d. per lb. Much cheaper.
Ammon. Carbonate B.P. £35 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make. Market neglected.
Barbitone.. .. .. 17s. per lb.
Benzonaphthol .. .. 5s. 6d. per lb. Supplies scarce. Some dealers quote more.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—
Per lb.
Potassium .. .. 9½d.—10d. } Market steady.
Sodium .. .. 9½d.—10d.
Ammonium .. .. 11d.—1s.
Calcium Lactate .. 2s. 9d. per lb. for best English make. Market firmer in view of shrinkage of imports.
Chloral Hydrate .. .. 4s.—4s. 3d. per lb. Firmer tendency.
Chloroform .. .. 2s. per lb. for cwt. lots.
Creosote Carbonate .. 6s. 6d. per lb. Little demand.
Guaiacol Carbonate .. 13s. per lb. for small stocks available. Slightly weaker.
Hexamine .. .. 3s. 9d.—4s. per lb. for foreign makes. Forward position very firm.
Homatropine Hydrobromide .. 30s. per oz.

Iron. Ammon. Citrate, B.P. 1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—
Light Commercial .. £36 per ton net.
Magnesium Oxide—
Light Commercial .. £72 10s. per ton, less 2½%.
Heavy Commercial .. £27 per ton, less 2½%.
Heavy Pure .. .. 1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—
A.B.R. recryst. .. 56s. per lb.
Synthetic .. .. 26s.—35s. per lb., according to quantity. English make.
Mercurials .. .. Firm and likely to advance.
Red oxide .. .. 4s. 11d.—5s. 1d. per lb.
Corrosive sublimate .. 3s. 8d.—3s. 10d. „
White precip. .. .. 4s. 6d.—4s. 8d. „
Calomel .. .. 4s. 1d.—4s. 3d. „
Methyl Salicylate .. 2s. 10d. per lb. for carboys. Quiet.
Methyl Sulphonal .. 21s. per lb.
Methylene di-tannin .. 7s. 6d. per lb. In good demand.
Paraformaldehyde .. 3s. 6d. per lb., without much inquiry.
Paraldehyde .. .. 1s. 7d. per lb.
Phenacetin .. .. 7s. 3d. per lb. Orders falling off.
Phenazone .. .. 8s. per lb. Weaker.
Phenolphthalein .. .. 8s. per lb. Price shaded for quantity. Ample supplies.
Potass. Bitartrate—
99/100% (Cream of Tartar) .. .. 88s.—90s. per cwt., less 2½%. Demand improving.
Potass. Citrate .. .. 1s. 8d.—2s. per lb.
Potass. Ferricyanide .. 3s. per lb.
Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite .. 7½d. lb., 1-cwt. kegs included.
Potass. Permanganate .. 9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin .. .. .. 6s. 3d. per lb. Firmer, though in little demand.
Salol .. .. .. 3s. 9d. per lb.
Silver proteinate .. 9s. 6d. per lb.
Sod. Benzoate, B.P. .. 3s. 3d. per lb. In better supply.
Sod. Citrate, B.P.C., 1923 1s. 10d.—2s. per lb., according to quantity.
Sod. Hyposulphite—
Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside .. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) .. 87s. 6d. per cwt. Market quiet.
Sod. Salicylate .. .. Powder 2s. 11d. per lb., Crystal at 3s. per lb., and good flake at 3s. 6d. per lb. Scarce on spot. Forward position distinctly firmer.
Sod. Sulphide—
Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous £27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal .. .. .. 18s. 6d. per lb.
Tartar Emetic .. .. 1s. 4d. per lb.
Thymol .. .. .. 13s. 6d.—13s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS.

Acetophenone .. .. 12s. 6d. per lb. Dearer.
Aubepine .. .. .. 13s. 6d. „ Slightly cheaper.
Amyl Acetate .. .. 3s. „
Amyl Butyrate .. .. 7s. 3d. „
Amyl Salicylate .. .. 3s. 6d. „
Anethol (M.P. 21/22° C.) 3s. 9d. „
Benzyl Acetate from Chlorine-free Benzyl Alcohol 3s. 3d. „
Benzyl Alcohol free from Chlorine .. .. 3s. 3d. „
Benzaldehyde free from Chlorine .. .. 3s. 3d. „
Benzyl Benzoate .. .. 3s. 9d. „ Slightly cheaper.
Cinnamic Aldehyde Natural .. .. 21s. 6d. „ Cheaper.
Coumarin .. .. 21s. „ Dearer.
Citronellol .. .. 19s. „
Citral .. .. .. 10s. „
Ethyl Cinnamate .. 10s. „
Ethyl Phthalate .. .. 3s. 9d. „
Eugenol .. .. .. 11s. „
Geraniol (Palmarosa) .. 37s. 6d. „
Geraniol .. .. .. 10s.—17s. 6d. per lb. Much dearer.
Heliotropine .. .. 8s. 6d. per lb.
Iso Eugenol .. .. 15s. 9d. „
Linalol ex Bois de Rose .. 20s. „
Linalyl Acetate .. .. 20s. „
Methyl Anthranilate .. 8s. 6d. „
Methyl Benzoate .. 6s. „
Musk Ketone .. .. 52s. 6d. „
Musk Xylol .. .. 19s. „
Nerolin .. .. .. 4s. „
Phenyl Ethyl Acetate .. 10s. „
Phenyl Ethyl Alcohol .. 16s. „
Rhodinol .. .. .. 60s. „
Safrol .. .. .. 1s. 10d. „
Terpineol .. .. .. 2s. 6d. „
Vanillin .. .. .. 25s. 3d.—26s. 6d. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. .. .. 14s. 6d. per lb.
Anise Oil .. .. .. 1s. 11d. „
Bergamot Oil .. .. 13s. 9d. „
Bourbon Geranium Oil .. 32s. 6d. „ Weaker.
Camphor Oil .. .. 75s. per cwt.
Cananga Oil, Java .. 9s. 4½d. per lb.
Cinnamon Oil, Leaf .. 5¾d. per oz.
Cassia Oil, 80/85% .. 10s. per lb.
Citronella Oil—
Java 85/90% .. .. 4s. 7½d. „
Ceylon .. .. .. 4s. „
Clove Oil .. .. .. 9s. 3d. „ Weaker.
Eucalyptus Oil 70/75% .. 2s. 4½d. per lb.
Lavender Oil—
French 38/40% Esters 24s. 6d. per lb.
Lemon Oil .. .. 3s. „ Advanced.
Lemongrass Oil .. 2¾d. per oz.
Orange Oil, Sweet .. 12s. 6d. per lb. Advanced.
Otto of Rose Oil—
Bulgarian .. .. 34s. per oz.
Anatolian .. .. 26s. per oz.
Palma Rosa Oil .. .. 22s. 6d. per lb.
Peppermint Oil—
English .. .. 70s. per lb.
Wayne County .. 16s. 6d. per lb.
Japanese .. .. 13s. 9d. per lb. Advanced.
Pettigrain Oil .. .. 9s. 6d. per lb.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1.) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

British India: Plain and corrugated galvanised sheets (95); *Egypt*: Steel (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, S.W.1., Ref. No. E.S.R. 49-3/2); *New Zealand*: Leather (96), Builders' hardware, crockery (97); *Switzerland*: Steel (108), leather (21675/F.W./M.C./2); *United States*: Rubber (114).

Trade Information

Thomas Tyrer and Co., Ltd., of Stirling Chemical Works, Stratford, London, E. 15, has issued a list of current prices of the well-known Stirling brand of chemicals, ranging from the common acids, alum, and nickel powder to mercurials, codeine, cerium oxalate and many fine chemicals. Terms of sale are given in the list, which should be consulted by every buyer.

British Drug Houses, Ltd., has issued a further edition of the valuable "B. D. H." catalogue of chemical products, which continues to grow in range and utility. Amongst the specialities are standard lactose for bacteriology, "A. R." acids of well-defined purity, a long list of indicators and buffer solutions for determining hydrogen-ion concentration, and a useful selection of test solutions and reagents.

A. Gallenkamp and Co., Ltd., has issued Part II of the catalogue of apparatus for industrial research. All kinds of apparatus—vacuum distillation, furnaces, centrifuges, electrolytic apparatus, calorimeters, viscometers, etc.—are listed, so that the catalogue should find a place in all research laboratories.

Lime is truly one of the "key" materials in chemical industry, and it is strange that consumers have, in the past, rarely insisted on having the best quality for their particular purpose. The Callow Rock Lime Co., Ltd., 810/11, Salisbury House, London, E.C. 2, however, have issued a valuable little booklet, entitled *Chemical Lime*, with the aim of demonstrating the importance of a pure standard lime to the chemical industry, and showing how the company produces such a lime. Methods of burning, the common impurities, and their effects, and the physical condition of lime, are discussed in short, but pithy, paragraphs, each conveying information that should be most useful to the consumer. After a chapter on "hydrate of lime," comes a long list of the uses of lime: in the manufacture of alkali, bleaching powder, ammonia, for softening and purifying water, depilation of hides, paint and distempers, for the hydrolysis of oils, etc., in making sodium soaps, as a flux, in brick making, and a number of chemical and other processes. The pamphlet concludes with a discussion of the physical and chemical properties of Callow Rock lime, compared with those of other limes. It is pleasant to see this Cinderella among chemicals treated with such respect, and it would pay consumers to do the same.

Carbonate of Ammonia is a well-known chemical, but its use in the bakery trade, in which it is known as "volatile salts," or "Vol," cannot be very widely known, though it is, perhaps, the most active member of that class of aerating agents known as "baking powders." Usually such powders contain sodium bicarbonate with tartaric acid, cream of tartar, or a phosphate, but although these materials produce good aeration, they leave a residue, a disadvantage not shared by carbonate of ammonia, which is converted completely to gas during baking. In addition, it has the advantages of purity, invariable composition, and greater gas-yielding power, whilst no gas is evolved until the mixture is in the oven, so that maximum aeration is produced when it is most wanted. To show the value of carbonate of ammonia as a baking powder, Messrs. Brotherton and Co., the well-known ammonia and tar distillers, of City Chambers, Leeds, have produced a most cheery pamphlet in gay covers, replete with recipes for making cakes, scones, and biscuits, all having been worked out by an expert baker. All these recipes require the use, as an ingredient, of carbonate of ammonia, which has been sold by Messrs. Brotherton as the Balloon Brand Carbonate, and has a reputation dating back over 30 years.

Boilermaking has reached a high degree of perfection, and as it is often associated with the manufacture of tanks, piping, cupolas, gas coolers and general plate work, it is of interest to note the catalogue illustrating the products of H. and T. Danks (Netherton), Ltd., Netherton, Dudley. This firm specialises in the erection of completely equipped boiler-houses—an advantage to the purchaser, in that one contractor is responsible for all the work—but its manufactures include steam receivers and other pressure vessels, superheaters, water softeners, vulcanising cylinders and steam-jacketed pans. Attention should be drawn to the "Danks" patent sectional water-tube boiler, which is particularly suited for erection in difficult or cramped positions, and is arranged so that sediment will be deposited, not in parts that should be free from it, but at the bottom in the rear sections, whence it is blown out.

Evaporation is one of the commonest of industrial operations, and in many chemical and manufacturing processes it is often the most important stage. Yet, from what one hears, far too much evaporation is conducted on an unsatisfactory basis whether scientific or economic, although highly efficient apparatus is available, and the theory of the process is well advanced. The firm of Blair, Campbell and McLean, Ltd., Govan, Glasgow, has manufactured all types of evaporating plant since 1838, and therefore has ample experience to place at the service of clients. A particular feature of this firm's productions is complete plants for the manufacture of sugar, glue, dyewood extracts, malt extracts, wood distillation products and various chemicals. The firm has designed many types of evaporators to meet practically all conditions, those in general use being the

Multiplex and Simplex patent film evaporators, the standard vertical evaporators, and special types for salting liquors. All these are illustrated and described in the company's catalogue of "Evaporating Plant," which contrasts the different types, discusses their operation and efficiency, and draws attention to special points. Those interested in the subject should consult the catalogue, if only for the figures showing performance and for the notes on the complete chemical plant which Messrs. Blair, Campbell and McLean supply, in addition to much other chemical plant of all kinds.

Export of Phosphates from Morocco

Exports of phosphates from Morocco in 1923 totalled 190,860 tons, distributed as follows:—France, 24,875 t.; Spain, 6136 t.; Portugal, 4707 t.; Great Britain, 17,493 t.; Holland, 51,504 t.; Belgium, 5199 t.; Czechoslovakia, 4394 t.; Sweden, 8648 t.; Italy, 11,622 t.; the local consumption amounting to 218 t.

French Company News

The Société de Pechelbronn has, since 1917, been extracting by means of wells and the monthly production from these wells alone has risen from 2800 tons at the beginning of 1923, to 3500 t. This process has confirmed the favourable estimates of the probable reserves in the Société's field, which covers 44,000 hectares (1 hectare = 2·47 acres), which are far from being exhausted by the 3500 borings put down so far. The replacement of borings by wells has shown the possibility of withdrawing from the soil, oil which cannot be extracted through borings; thus, after the exhaustion by borings and pumping, there still remains 2 to 3 times as much oil as has already been extracted. For example, No. I area has produced 91,106 t. since the sinking of wells in 1917, up to April 30, 1923, whereas the total production of the area exploited from 1887 to 1917 by 14 borings, which were supposed to have exhausted it, only reached 78,214 t. It is now estimated that this area will produce from 95,000 to 100,000 t. annually, by the exploitation of a deeper layer. It has now been decided to use a new method of treatment for the crude oils, which will permit of products of much higher commercial value than were previously attained.

The Société Alsacienne de Cokeries Alcok is erecting new coke ovens, and the gas produced will be utilised for town lighting by the Société du Gaz de Strasbourg, which is interested in the former company.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, FEBRUARY 8, 1924 No. 6

EDITORIAL

IN the year 1920 the Society of Chemical Industry and the Federal Council for Pure and Applied Chemistry discussed, on various occasions, the possibility of having a building, in some central position in London, which would accommodate, under one roof, the chemical societies and organisations which are now scattered all over the metropolis. It was hoped that such a building would be of great value to the science and industry, and that the effect of the scheme would be to add to the social life of chemists and save a great deal of time, energy and money. The late Lord Moulton drew up an appeal to chemists, the draft of which was privately circulated in the spring of 1921, but his death deprived chemists of a leader whose help and influence would have been of the greatest possible service to the chemical community. Since his death an appeal has been circulated, with the object of collecting in the first place a smaller sum, so as to lead the way to the larger scheme and to provide funds to entertain the foreign guests at the meeting of the Union Internationale in Cambridge last summer; after paying the Cambridge expenses the fund now consists of £150 Victory Bonds, £300 War Loan, £150 Funding Loan, £250 Conversion Loan and £200 India Stock. One thing has hitherto been lacking, a handsome donation to start the list of subscriptions. Such a gift not only encourages those who are engaged in circulating the appeal, but it stimulates others to follow the generous example. It is an example to the wealthy to give largely, and to those who are not wealthy to give the sums they can afford. The building, which is still a dream, every day becomes more nearly a reality, and though it may be long before the noble structure which chemistry deserves is erected, some building adequate to the present necessities of the industry and profession, and suitable for the accommodation of at any rate some of the most important societies, is quite possible even if the realisation of the full scheme must be postponed to a later date.

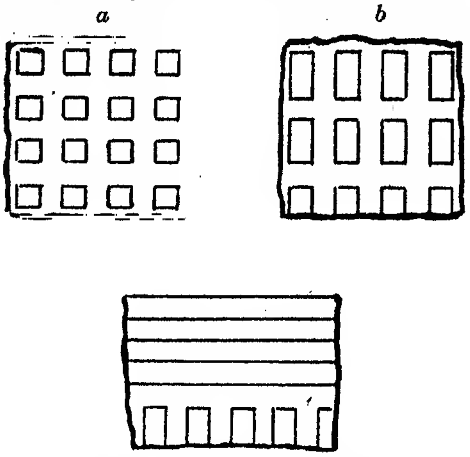
The generosity of the late Mr. W. J. Leonard has now given us that indispensable start which has hitherto been lacking. By a codicil dated in August, 1921, Mr. Leonard has set aside a sum of Five Thousand Pounds towards a scheme for the provision for the Society of Chemical Industry by themselves or in conjunction with other Chemical Societies, of a building and accommodation to form a Central Institute and Club for Chemists. The gift is conditional upon the carrying into effect of a definite scheme within seven years from the date of Mr. Leonard's death, and the exact terms of the bequest are too long for inclusion in an editorial note. At last we have a great opportunity, and it remains for us to take advantage of it. If we make the necessary effort, the success of the scheme is now assured. We shall now feel that during the next five or six years we must concentrate some portion of our energy on the realisation of this scheme. Half-a-dozen men can be of great help in this connexion, but the united effort of the great mass of chemists is necessary for complete success. There must be some thousands of chemists who can afford half-a-guinea a year for four years for such an object, and hundreds of chemists who can afford two or three guineas a year for this period of time. In the course of the next three or four years we shall successfully appeal to the great firms who can look on such a question with wise and large-minded views. When we appeal to them, it is very desirable that we shall be able to convince them that we who are the rank and file do not shirk from our own very agreeable duty. The President of our Society has on several occasions spoken of the co-operation of our various organisations; he has dealt with the matter in many different parts of England and Scotland, and it is worth while for our readers to turn again to the reports of his Presidential and other addresses which have appeared in our *Journal*. The man who has an opportunity of doing a good deed and does not take advantage of it does not remain *in statu quo*, he is just a shade lower in his own estimation. So, we fancy, says Carlyle or some other philosopher,

INDUSTRIAL FILTRATION

Part I.—British Chamber and Frame Presses

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

Filtration, the separation of solid matter held in suspension in a liquid by passing the liquid through a porous medium upon which the solid matter is retained, has very wide application in industry. Sometimes the problem consists in removing very



Drainage Systems for Filter Plates
FIG. 1

small amounts of solid matter from very large volumes of liquid, whilst in other instances the problem may be reversed. Naturally, therefore, the design and the medium used to effect filtration will vary considerably.

In chemical works in this country industrial filtration is effected to a large extent in machines known as chamber or frame filter-presses and it will be, therefore, with this type of plant that this article deals.

The chamber press consists of a number of recessed plates, carried on a suitable framing, and placed so that the recesses of two adjacent plates form a chamber when the plates are pressed together. In the frame type of filter press flat plates are used and the chamber is formed by inserting hollow frames between the plates.

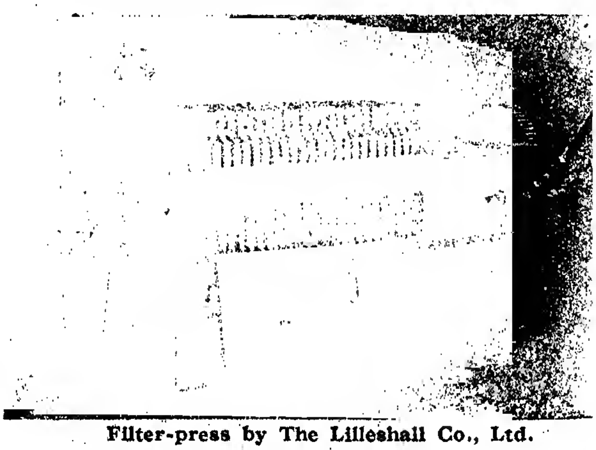
The liquor to be filtered is admitted to these chambers either through holes formed in the plates themselves or through ports in the frame which communicate with a passage situated at the outer edge of the frame and plates or in lugs formed on the outside of the plates and frames.

The filtering medium is placed over these plates and in order to provide adequately for its support and at the same time supply a suitable drainage system for the liquid passing through the medium, the central portions of these plates are corrugated. Figure 1 shows three well known types of corrugations. Type (a) is that adopted by S. H. Johnson and Co., Ltd., and is known as the pyramid drainage surface. It consists of a series of truncated square pyramids, the upper area in contact with the cloth being a square of about ¼ inch edge, whilst the depth of the grooves forming the sides of the pyramid is about 1/16 of an inch. That of Manlove Alliott and Co., Ltd., is a rectangular area about ¼ of an inch broad by ½ an inch long as shown in figure 1 (b), the long edges of the areas being vertical. The Premier Filterpress Co., Ltd., adopts a series of parallel grooves. Those at the top and bottom of the plates are cut horizontally and extend right across the plate. In the central portion of the plate between these horizontal grooves are a series of vertical grooves, the arrangement being as shown in figure 1 (c).

Sometimes perforated plates are used but these are occasionally objected to on the ground that they are difficult to clean, and being usually made of a different material from the press-plates are liable to excessive corrosion produced by electrolysis.

The object of all these devices is to produce a suitable support for the cloth with the minimum reduction in free filtering surface, and at the same time to provide a series of channels, by means of which the filtrate can be rapidly conveyed to the outlet. To prevent unequal stresses being put upon different portions of the filtering medium care is taken to ensure that all surfaces, in contact with the medium, lie in one plane. The edges of these surfaces are carefully rounded to prevent them cutting the filtering medium.

The outer rims of the plates, which in recessed plates extend considerably above the cloth supporting surface, but in plates for frame presses rise only slightly above this surface, are carefully machined on both sides of the plates. Every effort is made by press makers to ensure that the surfaces of the rims on each side of the plates and frames are parallel, for on this factor depends the closing of the press



Filter-press by The Lilleshall Co., Ltd.
FIG. 2

without leaking joints between the plates or plates and frames. The Lilleshall Co., Ltd., uses a disc grinder to face up the rims of plates and frames and guarantees an accuracy within plus or minus three-thousandths of an inch in the thickness of plate or frame.

At the bottom of each plate and connected with the grooves on either side of the plate by ports is

a hole through which the filtrate leaves the press. This hole may be fitted with a bib outlet, or a cock outlet or communicate with a closed delivery outlet passage cast in the plates and frames or in lugs attached thereto. When thorough washing of the cake is necessary, cocks must be fitted on these outlets.

Sometimes it is necessary to filter the liquor at a definite temperature above or below normal room

Filter-press by Messrs. Manlove, Alliott & Co., Ltd.
FIG. 3.

temperature. In these cases the filter plates may be cast hollow or have coils cast in the plates. This necessitates the provision of a supply channel with communicating ports through which the heating vapour or cooling liquid may be admitted to these coils or spaces, as well as an outlet channel for the removal of the condensed vapour or spent cooling liquid.

In some cases, this heating arrangement is unnecessary, the press being warmed by heating fluid admitted to the chambers before filtration commences. When the filter-press has been thoroughly warmed up the hot liquor to be filtered is admitted and if this is slightly above the minimum required temperature it is sufficient to make good the radiation losses from the press. When hot filtration under pressure has to be employed care should be taken to prevent supersaturation, etc., of the hot liquors leaving the filter-press, on account of rapid evaporation under reduced pressure. In order to eliminate troubles of this kind, it is necessary to have a closed outlet system so as to produce a suitable back pressure. This arrangement, however, will throw extra work on the pumping system. If the solid material in the filter-press has to be washed, this operation may be effected in two ways. These are known as "simple washing" and "thorough washing." In simple washing the wash water is admitted through the same channel as the liquor which has been filtered. In this case the flow of wash water through the cake will be in the same direction as the flow of the liquor. For satisfactory results with this method it is necessary that the cake should not be fully formed in order that the wash water may have access to the bottom as well as the top of the cake. This factor has the disadvantage of reducing the capacity of the filter press. As no special provision is required for the admission or removal of the wash water, the same openings being used as for the filtrate, this method can be adopted in filter presses not specially designed for washing the precipitates when an occasional washing is required.

In the thorough washing method the washing water is fed into the filter press, through a separate channel. This channel is connected by passages to the corrugated surfaces on either side of each alternate plate. The outlet cocks on the bottom of these plates are closed and the wash water is forced through the filtering medium, through the whole thickness of cake, through the filtering medium on the opposite plate, and out through the outlet cock on this plate, which is left open. Unfortunately this necessitates the flow of wash water through one medium, and one-half of the filter cake in the reverse direction from the flow of the liquor from which the cake was formed.

With this method of washing it is necessary to make provision for the escape of any air which may be in the filter press. If this is not done the air will prevent the wash water penetrating the upper portion of the cake, so that the top portion of the cake remains unwashed, and the lower portion is washed excessively.

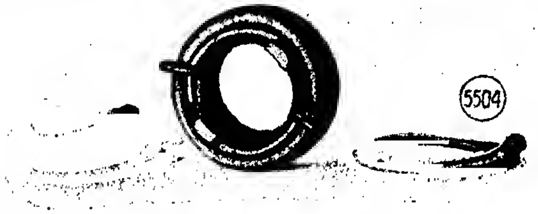
When the filtrate outlet is used as the wash-water outlet, even when air release has been provided, there is always the danger that the washing water may follow paths of least resistance through the cake, and thus cause unequal washing. To overcome this tendency the modern method is to place the wash-water supply channel at the bottom of the plate, the outlet for the washing water being arranged at the top of the plate. In this way the washing water floods the cake, thus producing uniform washing, and at the same time no special provision need be made for the removal of the air which can escape through this washing water outlet. With this arrangement provision must be made for closing all the openings through which the filtrate leaves the filter press.

Washing is employed either to recover valuable liquor adhering to the solid particles, or to free the particles from liquor adhering to them. In the first case it is usually advantageous to use the minimum amount of washing liquid, in order to keep this liquor as concentrated as possible; whereas in the second case where the filtrate is the valueless product of the filter press, the amount of washing water used will only depend upon how far the solid particles have to be washed free of the adhering liquid, and on the time which can be economically given to washing the precipitate in this manner. The time required to wash the precipitate to a required degree of purity will depend on the rate of flow of the washing liquid, and the nature of the liquid to be removed.

The rate of flow of the washing water will depend on the size and shape of the particles forming the precipitate, and on the pressure which is used to drive the wash water through the cake. Should it be necessary to dry the cake before removal from the filter press, provision must be made for the admission and removal of the drying gas, which is usually air.

This can usually be done through some of the existing channels.

The arrangement of these passages on the plates and frames of a filter press permits of a large number of variations. In the catalogue of S. H. Johnson and Co., Ltd., there are 15 varieties of plates of the recessed type, and about 22 varieties of flush plates



Bayonet Fitting of Messrs. Manlove, Alliott & Co., Ltd.
FIG. 4

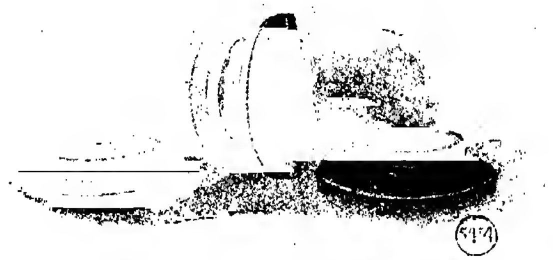
and frames. In the flush plate and frame type it is customary to form the supply and discharge channels or passages by a series of holes drilled in external lugs cast on the plates and frames. When this arrangement is adopted, a considerable wastage of filtering medium would arise if the filtering medium were extended so as to form the jointing material between these lugs.

In order to prevent this wastage of filtering material the joints are usually made by one or other of the following methods. One method consists in covering the lug with a cuff made of the same material as the filtering medium. Holes are cut in the cuff to correspond with the holes in the lug. In the second method the holes in the lugs of the frames are drilled larger than those in the lugs on the plates. Into these enlarged holes are fitted rubber rings. In cross-section, this rubber ring is channel-shaped in form, the flanges of this channel pointing towards the centre of the holes. The length of the rubber ring equals the thickness of the frame, and leakage is prevented by the fluid in the passage pressing these rubber flanges against the plates. Another method is to form the joint by means of a rubber ring which fits into a groove cut in the lug a short distance from, and concentric with, the passage.

The filtering medium covering these plates may consist of paper, cotton cloths, muslin and, for the filtration of strong alkali liquors, woven metal cloth, usually made of monel metal. Filtration through such fabrics should consist of the accumulation of the solid particles to be filtered on the surface of the medium. Particles which enter into and are retained by the cloth increase the resistance to the flow of liquid through the cloth, and therefore the time required for filtration. The true filtering medium is a layer or film of solid particles deposited on the surface of the cloth by the first portion of the liquor being filtered. This being so, the modern tendency is to use thin cloths, thereby lessening the possi[illegible] of the retention by the cloth of any particles which may penetrate its surface. Thin cloths possess two slight disadvantages, namely structural weakness, and the tendency to produce a large amount of cloudy filtrate before a sufficient deposit has been formed on the surface to act as the filtering medium.

The first of these disadvantages may be overcom by backing the cloth with some supporting fabri having meshes sufficiently wide not to interfere wit the free flow through the cloth.

The cloudy filtrate produced at the beginning o the run can be collected and returned to the sam press, or passed through another press kept speciall for that purpose. To prevent this cloudy filtrat filter aids have been adopted. These filter aid consist of sawdust flour, calcium sulphate, calciu carbonate, pulverised bone black, kieselguhr an proprietary articles such as Filter-cel, etc. A filte aid should possess the following properties: (a) i should mix with water, or the material being filtered so as to remain in suspension, and thus produce a uniform layer on the filter cloth; (b) its chemica composition must be such that it is inert or harmles to the materials being separated; and (c) it shoul provide a free filtering medium. The actual coatin of the cloth can be effected in three ways. In th first method a solution of the filter aid is pumped int the press until a clear filtrate is obtained. When th filtrate has become clear the contents of the press ar drained off. With this method compressed air mus be used to hold the coating of filter aid on the clot during the draining of the filter press. After drainage the press can be filled with the liquor to be filtered.



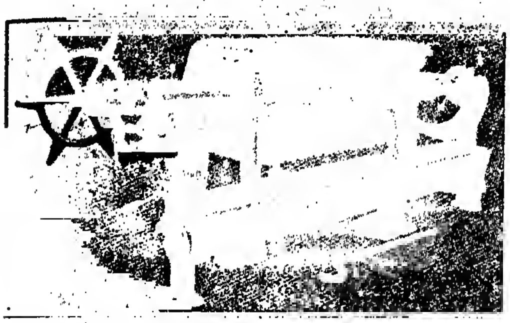
Screw Fitting of Messrs. Manlove, Alliott & Co., Ltd
FIG. 5

This method occupies a longer time and entail more attachments to the filter-press than either o the two following methods. The second metho consists in mixing the filter aid with some filtrat obtained from a previous batch, the quantity use being just sufficient to fill the press. After mixing this liquor is introduced into the press, gravitationa feed being usually employed for this purpose. Whe the filter-press is filled with the liquor containin the filter aid the regular liquor to be filtered i pumped in, and in forcing the contents of the filte press through the cloths, coats them with the filte aid. With this method neither drainage nor com pressed air systems are necessary. The third metho is usually employed when the solids are present i the liquor to be filtered only in relatively smal amounts. In this case it is found practical to mi requisite amount of filter aid directly into th [illegible]red liquor. The amount of filter aid use sh[illegible] be such that its volume far exceeds the volum of the solids in the material to be filtered.

Cotton filter cloths are usually made in thre varieties, namely, square weave, twill weave an

chain weave, but, as cotton is a cellulose product, porous weaves are liable to become dense on wetting. These cloths, being absorbent, are liable to fail at the gasket area on account of the filtrate not being washed out of the cloth at this area by the washing water. Painting this portion of the cloth with a tar base paint will render it non-absorbent and so increase the life of the cloth.

In clothing a filter press of the recessed plate type, two cloths are sewn together round the edges of the



Premier Filter-press, showing Angle-Lever Closing Gear (Premier Filter-press Co., Ltd.)
FIG. 6

holes cut in the cloths to correspond to the hole in the plate through which the liquor enters the chamber. One cloth is then rolled up and passed through this feed hole in the plate, and after unrolling is used to cover the reverse side of the plate. The top edge of each cloth is then attached to the top edge of the plate by clips or hooks. In this way the cloths hang in the correct position until the press is closed, when, as the cloths form the jointing material between the plates, the rims of the plates will retain the cloths in the correct position. Sometimes this sewing together of two cloths at the feed opening is dispensed with, and then the cloth is firmly clamped to the plate round the feed opening by a bayonet or screw fitting (Figs. 4 and 5).

In the plate and frame type of filter press the cloth is cut slightly longer than double the depth of the plate, and is hung over the top of the plate in such a manner that one-half of the cloth hangs down and covers one side of the plate, the other half covering the other side.

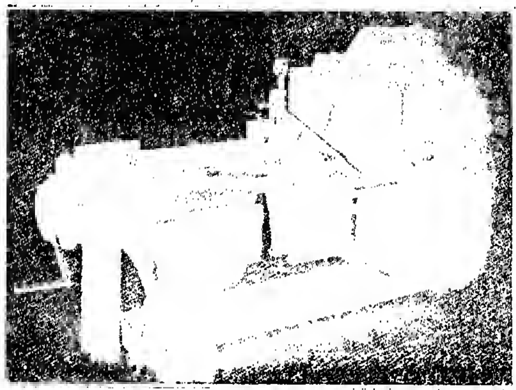
If the various feed and outlet holes are formed in the outer edge of the plates and not on lugs attached thereto, corresponding holes must be cut in the cloths so that they are concentric with these feed and outlet holes. Here, again, the cloths or filtering medium form the jointing material between the plates and frames.

Another point upon which a considerable amount of ingenuity has been displayed by various makers is the closing gear. The objects aimed at in this mechanism are: (a) to exert such a pressure, which must be applied uniformly round the joints between plates and frames, that leakage will be prevented; and (b) that the filter press can be properly closed, or fully opened to allow of the discharge of the cakes, in the least possible time and with the minimum labour.

The simplest form of closing gear consists of a screw, acting through a nut carried in the back standard of the filter press. One end of this screw presses against the centre of the follower plate, and the other end is fitted with the gear, through which the screw is rotated. This turning gear may consist of a ratchet and pawl device on the smaller sizes of filter press. On the larger sizes pinions and tooth wheels, helical wheels, worm and screw gear are employed. The Premier Filterpress Co., Ltd., in small sized machines, carries this centre screw in a rotating nut mounted on the back standard. By this device, as soon as the end of the screw is free from the follower plate, the screw can be tilted out of the way. Another type of closing gear consists of a rack and pinion, the rack being attached to the follower by a flexible joint and the pinion being mounted on the back standard. The pressure is applied by nuts operating on the side rods which are screwed to suit the nuts, and distance pieces are provided so as to minimise the travel of these nuts.

Another type of closing gear consists of the angle lever arrangement shown in Fig. 6. In this type two angle levers are used; the fulcrum situated at the end of the shorter arm is attached by a pin to bosses cast on the head of the press. The side rods are attached to the other ends of the shorter arms, whilst the outer ends of the longer arms are connected by a right and left-handed screw working in swivolling nuts carried by these arms. A hand wheel rotates this screw and operates the gear.

Numerous hydraulic closing devices have been adopted. These usually consist of a hydraulic cylinder carried on the back standard of the filter press, the ram of this cylinder thrusting directly on a



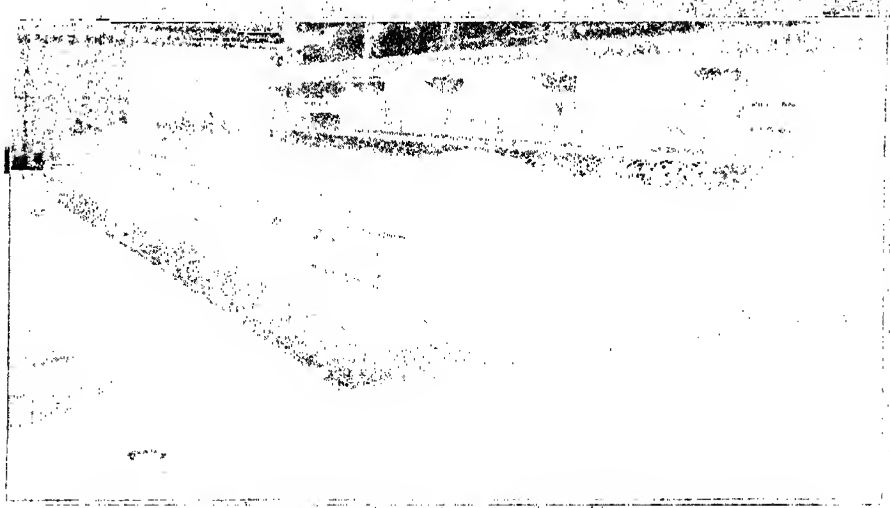
Pyramid Filter-press, showing Hydraulic Closing Gear (S. H. Johnson & Co., Ltd.)
FIG. 7

central boss of the follower. A small hydraulic hand pump is usually provided to give the pressure required for tightening the filter press. S. H. Johnson and Co., Ltd., has a patent hand hydraulic tightening gear which is illustrated in Fig. 7. A small hydraulic cylinder complete with pump, etc., is mounted on the follower. A closing screw carried on the back standard can be rapidly run out until it comes into contact with the ram of the hydraulic cylinder.

Pressure is then applied to the ram, and since the latter cannot move, the cylinder moves forward against the follower. A lock nut on the screw can then be screwed into position, thereby eliminating the necessity of maintaining the hydraulic pressure during filtration, etc. When hydraulic closing gear is adopted in the larger sizes of filter-press, it is customary to provide additional mechanism for the withdrawal of ram and follower when the pressure has been released. These devices may be either of the counter-balance weight or the hydraulic type.

The number of chambers in the filter press varie from six in the smallest to sixty in the largest sizes.

A. F. Craig and Co., Ltd., is at present engaged on a large order for a series of filter presses, speciall designed for the filtration of paraffin wax. This type of press has been developed in America, and has been used solely in connexion with wax extraction in oil refineries, and this is the first time that similar filter presses, embodying the salient features of their American prototypes, have been manufactured in this country. Each of these filter presses possesses five hundred filter plates, each four feet in diameter. The oil is fed into the filter press at a pressure of 500 lbs. per sq. in. in order to obviate the old and expensive method of subsequent pressing in vertical hydraulic presses. The hydraulic cylinder is designed to work at a pressure of 800 lbs. per sq. in.



Filter-presses for Paraffin Wax by Messrs. A. F. Craig & Co., Ltd.

FIG. 8

The materials used in the manufacture of filter-presses naturally depend upon the chemical properties of the substances to be filtered. Usually the standards, head and follower, are made of cast iron, and the side rods of steel. In special cases where cast iron would corrode rapidly or damage the filtered product, the facings of the head and follower as well as the plates and frames, may be made of gun-metal, bronze, aluminium, antimonial lead, or wood. By far the greater number of plates and frames, however, are made of cast iron, on account of its cheapness and durability. When wood is employed it is necessary, when the filter press is not in use, to close the filter press and fill it with water to prevent warping of the plates and frames. Recently the firm of Manlove, Alliott and Co., Ltd., has carried out an interesting series of experiments to find out the effect upon the stresses, by prolonged immersion in different acids, at different concentrations. Usually pine is the wood employed in the manufacture of plates and frames, but where discolouration of the filtrate is to be avoided maple wood is to be preferred.

Standard frame and plate filter-presses vary in size when made of cast iron from plates 12 inches square, to plates 51 inches square, and when made with wooden plates and frames from rectangles 18 in. by 12 in., to 46 in. by 33 in.

As the working pressure plays an important part in filtration operations, the plant for its production requires consideration. In forming a cake the pressure should be applied gradually, until the maximum is reached, and this should be maintained as constant as possible throughout the remainder of the filtering period. If ram or plunger pumps are used the pressure is liable to fluctuate, thus compressing the cake and altering the resistance to the flow of liquid through it. Trouble, too, is often experienced with this type of pump, due to grit being deposited on the valve seats. To maintain a uniform pressure and to overcome valve troubles, montejus have been adopted, but these usually occupy a large floor area, and requiring compressed air for their operation, are often expensive to run. An economical type of pressure-producing plant has been found to be the rotary displacement pump, which occupies little floor space, has positive action, does not suffer from valve troubles, and does not tend to agitate the liquor unduly, like the centrifugal pump if the pump

capacity exceeds the outflow of the press, and supplies the liquor to the filter press free from pulsations. With this type of pump, however, provision should be made for by-passing any excess liquor back to the suction tank.

The complete cycle of operations required for filtration consists of :—(*a*) coating the filtering medium with the filter aid if this is used ; (*b*) filtering the liquor ; (*c*) washing the cake if required ; (*d*) drying

Filter-press by Pratchitt Brothers

FIG. 9

the cake if necessary ; (*e*) opening machine, discharging the cake, and examining the filter cloths ; (*f*) closing the machine in readiness for handling the next batch. For efficient working the time occupied in filtration should occupy as large a percentage of the total cycle as possible, and the time of the other operations should be as small as possible.

As will be seen a large number of factors, as well as the quantity of material and its chemical nature, come into play in the successful design of filter presses. Realising this several manufacturers of filter presses have installed at their works semi-scale laboratories, in which information necessary for successful design can be obtained by actual tests on the material to be filtered, under conditions similar to those prevailing in the full-sized plant.

Thanks are due to Messrs. S. H. Johnson and Co., Ltd., Manlove, Alliott and Co., Ltd., The Premier Filter Press Co., Ltd., A. F. Craig and Co., Ltd., The Willeshall Co., Ltd., Pratchitt Brothers, Bruce and Hyslop, Ltd., Brinjes and Goodwin, Ltd., and other makers, for their courtesy in giving information and granting the use of their illustrations.

The late Mr. W. Prescott, head of Messrs. Prescott and Co., cotton brokers, Liverpool, who left estate valued at £135,182, bequeathed "a sum of £20,000 to the Liverpool University for the founding of a chair of agriculture or of some cognate subject, such as agricultural chemistry, the study of crops, or kindred lines of investigation."

FORTHCOMING EVENTS

Feb. 12. INSTITUTION OF PETROLEUM TECHNOLOGISTS, The Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "Electricity Applied to the Winning of Crude Petroleum with Special Reference to the Yenangyoung Field, Burma," by C. H. McCarthy-Jones.

Feb. 12. ROYAL PHOTOGRAPHIC SOCIETY, *Scientific and Technical Group*, 35, Russell Square, W.C. 1, at 7 p.m. "A New Density Meter," by F. C. Toy, D.Sc., and S. O. Rawling, B.Sc.

Feb. 12. ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 5.15 p.m. "The Respiratory Pigments in Animal Life," by Prof. J. Barcroft. Also on February 19 and 26.

Feb. 13. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 6 p.m. "The Contributions of Sir Francis Galton to Photography," by K. Pearson, F.R.S.

Feb. 13. ROYAL SOCIETY OF ARTS, W.C. 2, at 8 p.m. "The Preservation of Timber from the Death Watch Beetle," by H. M. Lefroy.

Feb. 13. INSTITUTE OF METALS, *North-East Coast Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "Propeller Brass," by A. Logan.

Feb. 14. INSTITUTE OF METALS, *London Section*, 85-88, The Minories, Tower Hill, E. 1. "Metals for Lamp Manufacture," by W. B. Clarke.

Feb. 14. MANCHESTER COLLEGE OF TECHNOLOGY CHEMICAL SOCIETY, at 4.30 p.m. "Osmosis and Osmotic Pressure," by Prof. J. S. Haldane, M.D., F.R.S.

Feb. 14. SOCIETY OF DYERS AND COLOURISTS, *London Section*, The Dyers' Hall, Dowgate Hill, E.C., at 7 p.m. "Staining and Dyeing," by Prof. J. F. Thorpe, C.B.E., D.Sc.

Feb. 14. OPTICAL SOCIETY. Annual General Meeting, Imperial College, South Kensington, S.W. 7, at 7.30 p.m.

Feb. 15. INSTITUTE OF METALS, *Swansea Section*, Metallurgical Department, University College, Singleton Park, Swansea, at 7.15 p.m. "Fatigue and the Elastic Limit," by Prof. C. H. Desch, D.Sc.

Feb. 15. SOCIETY OF CHEMICAL INDUSTRY, *Swansea Meeting*, Technical College, Mount Pleasant, Swansea, at 7.15 p.m. "Paper," by Messrs. L. Taverner and H. J. Williams.

Feb. 15. WEST OF SCOTLAND IRON AND STEEL INSTITUTE, Royal Technical College, George Street, Glasgow, at 7 p.m. "Recent Advances in the Study of Corrosion," by J. Newton Friend.

Feb. 15. SOCIETY OF DYERS AND COLOURISTS, *Manchester Section*, 36, George Street, Manchester. "Some Physical Properties of Yarns," by A. E. Oxley, M.A.

Feb. 15. ROYAL SOCIETY OF ARTS, W.C. 2, at 4.30 p.m. "Salt Manufacture in India and China," by Sir R. M. Dane, K.C.I.E.

Feb. 16. THE BRITISH ASSOCIATION OF CHEMISTS, *London Section*. Annual Dinner, Engineers' Club, Coventry Street, W. 1.

Feb. 16. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*. Annual Dinner to be held jointly with the local section of the Institute of Chemistry at the Hotel, College Green, Bristol.

BUREAU OF CHEMICAL ABSTRACTS

As already announced, the Bureau of Chemical Abstracts was formed in the latter part of 1923, as the result of a joint agreement between the Councils of the Chemical Society and the Society of Chemical Industry, with the object of co-ordinating and, if possible, unifying the abstracts hitherto published separately by the two Societies. The work of the Bureau is in the hands of a Committee consisting of four representatives from each Society, with Prof. J. C. Philip as Chairman.

The Bureau was, at an early stage, called upon to deal with the position created by the resignation, through ill-health, of Mr. A. J. Greenaway, who was connected, for a long period of years, with the publications of the Chemical Society. His experience, fortunately, is at the disposal of the Bureau in its re-organisation of the production of abstracts.

The Bureau has now arranged for a single homogeneous editorial staff, which will, in future, be responsible for the preparation and production of the abstracts both in pure and applied chemistry. The chief Editor, who will be responsible for the organisation of the scheme and the general control of the abstracts, is Mr. T. F. Burton, who for the past nine years has been Editor of the Transactions and Abstracts issued by the Society of Chemical Industry.

The further decision has been reached that the abstracts in each particular section should, as far as possible, come under the review of an Assistant-Editor, with special knowledge of the subjects covered by the section. The Bureau has, accordingly, appointed the following as Assistant-Editors :—H. M. Dawson (General and Physical chemistry), A. A. Eldridge (Inorganic and Analytical chemistry), W. E. Garner (General and Physical chemistry), H. J. Page (Biochemistry), E. H. Rodd (Organic chemistry; aromatic division), A. Shonk (Applied chemistry), E. E. Turner (Organic chemistry; heterocyclic division), H. Wren (Organic chemistry, aliphatic division).

It is felt that this move in the direction of securing unity in editorial and technical control represents a distinct step towards the achievement of the objects of the Bureau.

SOCIETY OF CHEMICAL INDUSTRY

LONDON SECTION

On February 4, a meeting was held in the Engineers' Club, jointly with the Chemical Engineering Group, to hear a paper by Prof. J. W. Hinchley on "The Manufacture of Potash and Other Salts from Leucite." Dr. Bernard Dyer presided, supported by Mr. J. A. Reavell, M.I.M.E., M.I.Chem.E., and there was a very good attendance.

Owing to pressure on our space it has been found impossible to give an account of the meeting in the current issue, but the paper will be given in full in the forthcoming issue of *Chemistry and Industry.*

MANCHESTER SECTION

A meeting was held on February 1, and Dr. Ernest F. Ehrhardt read a paper, entitled "Reminiscences of Dr. Caro." Dr. H. Levinstein presided, and about 40 were present.

Dr. Heinrich Caro was born in 1834, and when he left college, in Germany, he became a calico printer in Mulheim, Alsace. Later he was sent to England by his employers to buy machinery, and was then so favourably impressed that he determined to return to this country as soon as possible. So about 1855–6 he came to Manchester, remaining there 12 or 13 years before returning finally to Germany.

The name of Dr. Caro was frequently used as a sort of fetish. Frequently, when the question of educating industrial chemists was discussed people would advocate the adoption of the German system, and instance Dr. Caro as one of its best products. Dr. Caro, however, was never educated as a chemist, for, although he did learn the elements of chemistry, he was essentially a calico printer. The dyestuffs industry was only just born when he commenced his business career, and it was from this point of view that he studied the science.

While in Manchester he was engaged by Messrs. Roberts, Dale and Co. to do some chemical analysis, according to his own statement, for a remuneration of £1 per week, whereas another account places it at 30s. The difference in the two amounts would probably be considered substantial at that particular period. It was a modest beginning for a man who subsequently became a German "millionaire." Aniline colours had been invented by Perkin, who had produced his famous mauve. Caro also began to interest himself in the same direction in a manner which might possibly be considered somewhat singular. At that time nitrobenzene was used for scenting soap for barbers, and Caro made his first product from this scent. He tried printing aniline on cotton, and hit upon an aniline-black process for printing cotton black. This success so impressed Roberts, Dale and Co. that they took him into partnership. He remained with the firm for 10 years, and then returned to Germany, with a competency, for the purpose of undertaking research work at the University of Heidelberg. At that particular period the author of the paper happened to be churchwarden in the English church of Heidelberg, and was present at the first christening there, which was that of Caro's eldest daughter.

The Mannheim-Ludwigshafen factory (Badische Anilin u. Soda Fabrik) was then in its infancy, and its managers constantly consulted Caro, finally persuading him to join their undertaking as head of the research department. He stayed with them 25 years, and then took a seat on the Board. He was a difficult man to get on with, and was constantly quarrelling with his colleagues. Having served his first term of five years as a director, he was, in consequence, not reappointed, but was "promoted" to the Supervisory Board, a sort of committee of inspection appointed by the shareholders.

While Caro was in Manchester, Roberts, Dale and Co. had installed a new plant for the manufacture

of oxalic acid. A friend of the firm came to them who had discovered a way of making the acid by bubbling coal-gas, as it was supplied in those days, through nitric acid. Caro investigated the process, and it was soon obvious that it would prove more expensive than the use of sawdust which was then the usual raw material for the manufacture of oxalic acid. Caro, however, noticed that in bubbling the coal-gas through the nitric acid a little nitrobenzene was formed. This was the raw material for making aniline, and, in those days, was very expensive. Roberts, Dale and Co. were at once appalled at the prospect of nitrobenzene being made in that way, thus causing oxalic acid to become a by-product, and their oxalic acid plant to become worthless. The process was promptly condemned, and a discreet silence maintained about it. Many years later the matter became of importance in Germany. The German tar distillers combined and put up the prices of benzene and other crude products to the dyestuffs factories. Caro remembered his old Manchester experiment, and began a repetition of it in his writing-room on the window sill. While the experiment was proceeding, a visit was paid by Prof. Witt, a German who had also been in Manchester, and who had become a professor at the Heidelberg Polytechnic. Caro drew the window curtains to hide the beaker, and then went out with Witt, forgetting all about his experiment. The gas bubbled through the beaker all night. Next morning Caro found there was a little oxalic acid in the nitric acid, but not sufficient to be of any importance. What was important, however, was that on the top of the nitric acid there was quite considerable layer of oil, and upon analysis it proved to be benzene containing a little nitrobenzene. The action of the nitric acid on the benzene in the gas had produced nitrobenzene, and this had acted as a solvent and scrubbed the gas of its benzene. It was thus demonstrated that coal-gas contained a considerable quantity of benzene. Further experiments were made with more suitable solvents, a counter-alliance was entered into with the gasworks undertakings, and, in the end, the combine of the profiteering tar distillers was routed.

Caro always emphasised the element of chance in discoveries. His invention of the commercial process for making alizarin was an instance. The first production of artificial alizarin had been by the Geneva chemists, Graebe and Liebemann. They made dibromanthraquinone which they melted with caustic alkali. They had repeatedly tried to use cheap vitriol for the process, instead of expensive bromine, but had failed. The result was commercial failure. The Badische Anilin u. Soda Fabrik had acquired a considerable quantity of anthraquinone which was apparently wasted. Caro set to work to find some use for it. He made a dye from carbolic acid by treating the carbolic acid with vitriol and oxalic acid, and then decided to make the same experiment with anthraquinone instead of carbolic acid. The experiment was made in a porcelain dish in the laboratory, and as the acid mixture got hotter the oxalic acid decomposed and volatilised. The experiment was a failure. Just then, Caro was called away, forgetting to remove the flame from under the porcelain dish. The vitriol went on boiling in his absence, and, upon his return, the laboratory was full of fumes, the mixture in the dish had evaporated to dryness, and there was a partly charred crust of material around the upper edge of which was a thin pink line. The boiling sulphuric acid had acted on the anthraquinone to give a sulpho-acid, whilst the charring had decomposed some of the sulpho acid into alizarin, which, with a trace of alumina from the porcelain dish, gave the pink line. This started Caro again on the sulphuric acid process. He took the strongest fuming acid available, and worked at a high temperature, obtaining anthraquinone, sulpho-acids, alizarin, and its isomers, from it. At this particular period, W. H. Perkin (later Sir William Perkin) was also working independently at the same problem and solved it, but Caro had the good luck to get his patent into the English Patent Office one day before Perkin. Caro's patent was 1938, June 25, 1869, and Perkin's patent was 1948, June 26, 1869. But for Caro's good luck, the English market for alizarin, which was the principal and almost the sole one, would have been closed to the German manufacturers.

A paper on "The Dehydration of Alcohol by Means of Glycerin," by Prof. E. Knecht, Ph.D., M.Sc., Tech., and E. F. Muller, B.Sc., Tech, was read by Prof. Knecht, who stated that it was well known that pure glycerin readily took up a certain proportion of water, which it retained tenaciously at the boiling point of water, and even beyond that temperature. It was considered of interest to ascertain whether this property might be utilised for the dehydration of ordinary alcohol, with a view to working out a rapid and convenient process for the preparation of absolute alcohol. In a preliminary experiment some ordinary alcohol of about 92 per cent. strength was mixed at random with glycerin and distilled from a water bath; pure alcohol came over, though it was fairly obvious that this would be the result. In order to ascertain to what extent pure alcohol is retained by pure glycerin at 100°, a quantitative distillation was carried out. To this end absolute alcohol was mixed with 25 per cent. of pure glycerin, the mixture being distilled from a water bath, and the distillate collected in a flask provided with a loosely-fitting cork. The following quantities were taken: 40 g. absolute alcohol, 10 g. pure glycerin. The mixture was distilled until no more liquid came over at the temperature of the water bath, and yielded 37·8 g. alcohol recovered, so that 2·2 g. had remained in the glycerin, this being equivalent to 5·5 per cent. of the alcohol taken. By heating the residue in the flask to 180° a further recovery of 2·15 g. alcohol was effected, and there was practically no loss. The method gave a satisfactory product with very little trouble, and in sufficiently good yield to be of some practical value in the laboratory.

Dr. J. M. Francis, chief chemist to Parke, Davis and Co., Detroit, died on January 9. Otto J. Laist, a chemist who had done much work in the refining of glycerin, died on January 2, aged 89.

OTTAWA SECTION

A meeting was held in the University Club, Ottawa, on January 10, Dr. Macintyre in the chair, and there was a good attendance. The minutes of the last meeting were read and approved. The financial statement for the year 1923 was read and showed a balance on hand of $112·86. The motion by Dr. Shutt and Col. Janson that the report be adopted was carried.

Dr. Shutt called attention to Russell's book, "The A B C of the Atom" and the chairman referred at some length to "Die Methoden der Organischen Chemie," by Weyl. Mr. N. Van Patten, Librarian at Queens University and formerly of the Massachusetts Institute of Technology, then addressed the meeting on Chemical Literature. He said that in attempting to speak of chemical literature and its uses some attention should be paid to the historical background, with emphasis on the continuity of the science. In 1872 a manuscript was discovered at Thebes which treated of the practice of medicine and the preparation of pharmaceuticals. The date of the manuscript was placed in the 16th century B.C., and it was the earliest medical work on record. Chemistry was known in the early period around the 16th century as the sacred art, and its practice was confined to the Priesthood. Its literature was written in an obscure and figurative language, and was made up of a wonderful conglomerate of science, religion, astrology and symbolism. Reference was made to the records of Chinese and Arabian alchemy. During the Middle Ages the schools and libraries were controlled by the clergy and practically all works of alchemy were the production of persons attached to the Church, such as Roger Bacon, born in 1214, Raymond Lully, a Friar born in 1235, and Albertus Magnus, a Bishop, born in 1193.

Geber stated the qualifications necessary to a chemist as diligence, patience, learning, temperate disposition, slowness to anger and a full purse. "For this Science agrees not well with a man poor and indigent." Reference was then made to the work of several of the early alchemists. Modern journal literature has increased in volume until we now have in excess of 2000 journals, and perhaps as many more serial publications devoted to chemistry and chemical technology. The Columbian Chemical Society existed in Philadelphia as early as 1811, and such societies have multiplied greatly, so that we have a large number of such societies dealing with general and specific phases of the science.

Mr. Van Patten then outlined a method of investigating literature relative to a particular subject and suggested that it would be well if all such inquiries could be done by librarians or chemists specialising in such work. This is now being done in a number of corporations such as the General Electric Co., General Chemical Co., etc., and the practice has proved decidedly worth while, and such library activities are more than paying their own way. Some libraries, such as that at the Massachusetts Institute of Technology, have a system of keeping members of the staff, students and subscribers informed regularly on subjects of special interest to them and information is supplied on any special subject desired. The speaker hoped that Queens Library would soon be able to render a much needed service to Canadian scientists. Reference was made to Bulletin No. 36 of the National Research Conference containing a list of publications in chemistry and chemical technology and to the pamphlet printed by Chemical Abstracts, giving a list of all the chemical journals abstracted. Comprehensive reference was then made to the standard works on the various phases of chemistry and to reports and official publications on these subjects.

A very interesting discussion followed the address, during which Mr. Van Patten explained the Dewey decimal system of classification and also referred to the United States Libraries of Congress Classification. Mrs. O'Gilvie gave an interesting short account of the system used in the Mines Branch Library (a modification of the Dewey System.) The manner of working up information on a specific subject brought forth an interesting discussion between Mr. Elworthy, the chairman, and Dr. Wilson. Dr. Macintyre referred to Notes on Chemical Literature and its use compiled by Marion E. Sparks.

YORKSHIRE SECTION

Dr. L. L. Lloyd presided at the fourth meeting of the Session, held in Leeds on January 28, when a paper by W. B. Atkin and G. W. Douglas on "Proteins as Chemical Compounds" was read.

In consequence largely of the work of Procter and Wilson in Leeds and of Loeb in America, proteins are no longer regarded simply as "colloids," and peculiarities in their behaviour towards acids and alkalis, hitherto "explained" by adsorption and other vague terms are gradually being eliminated. In truth the solubility in acid and alkali is due to chemical combination.

Gelatin, according to Procter, forms salts with acids capable of ionising and variations in swelling are correlated with osmotic pressure effects, whilst Loeb demonstrated their amphoteric character with an isoelectric point at p_H 4·7. The titration results of Harris and Hopkins with lysine with the corrections introduced showed clearly how their curve for lysine was made up of two neutralisation curves, and gelatin was examined by the authors in a similar manner.

Carefully purified gelatin (which does not set to a jelly, but is gradually precipitated), was made up to 1 per cent., and titrated with acid and alkali at 25° C., using a hydrogen-electrode apparatus, and correcting for hydrolytic effects. The gelatin was neutralised by hydrochloric acid at p_H 3·65, corresponding to a combining weight of 1100 and by caustic soda at p_H 5·65, combining weight 3000. Further, after p_H 7, there is evidence that soda is being attached, in other words, the gelatin is behaving like a weak polybasic acid. These results were shown to be in agreement with calculations made from the results of Dakin's work on the nature of the gelatin molecule.

NOTTINGHAM SECTION

At a joint meeting with the Society of Dyers and Colourists (Midlands Section) held on January 30, a paper entitled "The Progress of Research in the Ionamine Dyestuffs," by A. G. Green, F.R.S., and K. H. Saunders, B.A., B.Sc., was read by Mr. K. H. Saunders.

Ionamine dyestuffs were obtained by causing aldehyde bisulphites to combine with aminoazo compounds, to form alkyl omega sulphonates of the type $PhN_2C_6H_4NH.CH_2SO_3Na$. In the dye bath hydrolysis occurred with the liberation of the free base which dyed the yarn in fabric. The two chief advantages of these dye bases were their solubility in water, and their miscibility with direct cotton colours, so that a great variety of effects could be obtained with union goods. The first ionamines produced ranged from yellow to orange, and extension of the work to obtain deeper shades involved use of diazotisation and development. The technical difficulties involved in such treatment were enhanced by the slowness with which both nitrous acid and developer penetrated the fibre, often necessitating warm coupling baths.

The fastness of the original Ionamine B dyes was satisfactory, and research was directed towards extending the range of colours by producing dyestuffs which were insoluble in water, possessed an affinity for cellulose acetate and contained a free amino group, to which could be attached the solubilising alkyl omega sulphonic group. The production of blue dyestuffs was aimed at, as it has always been found difficult to obtain blue dyes possessing an affinity for cellulose-base silk. The gallocyanine bases possess this property and it was found possible to prepare the corresponding alkyl omega sulphonates of this class. These dyestuffs were of even penetration and fast to soap, but extremely fugitive to light. Attention was then turned to alkyl omega sulphonates of the aminoanthraquinone class, and successful results were obtained in the production of dyes which penetrated evenly into the twist and were fast to light; further, as cotton was not stained these dyestuffs were suitable for unions. In discussing the application of Ionamine dyes, it was observed that difficulties arose in the dye house that did not occur in the laboratory. The causes of the defects of "barring" (alternate bars of light and dark shades) were considered and remedies suggested.

Describing the phenomenon of "phototropy," the speaker said that if a portion of a piece of yellow dyed cellulose acetate was shielded from the light for a few minutes, and the shield then removed, a lighter patch was seen, which quickly darkened to the original colour. No satisfactory explanation had been found to account for this peculiar effect, and so far a pure greenish-yellow dyestuff entirely free from phototropy had not been obtained.

The Ionamine dyestuffs had now been obtained in the primary colours, and by mixing, almost any shade (except black) can be produced.

The other method for dyeing cellulose acetate silk is by using insoluble compounds, which were held in colloidal solution by such dispersing agents as Turkey Red oil. This method would seem to be accompanied by a larger number of difficulties than the Ionamine process.

The lecture was illustrated by many dyed patterns showing the range of direct dyeing Ionamines, both alone and in conjunction with direct cotton colours.

In the discussion Mr. Pomphrey inquired how the Ionamine-dyed cellulose acetates compared with the fastness of wool colours to chlorination and stoving. Mr. Pentecost asked whether the cellulose acetate was constant in composition, or whether different samples responded differently. Mr. Wolstenholme mentioned some samples dyed a good black with Ionamine A black, but others (in the same bath) were bronzed, and had to go back into the bath again. Mr. L. S. Pentecost enquired whether the lustre could be restored to a "blinded" fabric. Mr. H. B. Mayfield referred to the different shades sometimes obtained, when dyeing slack and stiff varieties of cellulose acetate. Mr. Ellis mentioned that phototropic effects were also noticed with certain red and orange dyestuffs.

In reply, Mr. Saunders stated that fastness varied considerably, according to the particular type of Ionamine dyestuff, and also according to the chemical used. In stoving it was probable that the cellulose acetate would be injured before the colouring matter. There was a noticeable difference in the quality of different batches of cellulose acetate. Thus sometimes it was found possible to force compounds with higher molecular aggregations into the cellulose than at others. The "blinding" during developing was due to the dyestuff crystallising out, and it was not possible to restore the original lustre. The bronzed effects when using Ionamine A black were probably due to insufficient diazotising.

CANADIAN PACIFIC SECTION

The Canadian Pacific Section held a meeting on November 7, in the Board of Trade Building, Vancouver, B.C.

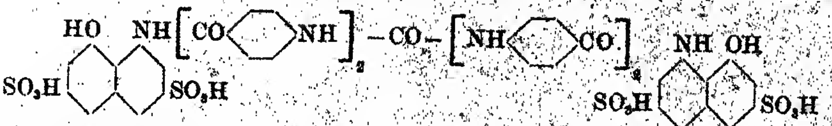
Dr. W. F. Seyer of the Chemistry Department, University of British Columbia, spoke upon the "Chemistry of Lubrication," and reviewed the work of Towers, Regnault, Southcomb, and Wells and Deely, as well as the recent work of Hardy. Their results led to two conceptions of lubrication—boundary lubrication and flooded lubrication, oiliness being a physical property which determined the efficiency of substances as lubricants under boundary conditions. He then described experiments carried out by himself, using Hardy's method of measuring the coefficient of friction, and gave a number of results obtained with mixtures of organic compounds whose chemical composition and viscosities were similar to that of mineral and vegetable lubricating oils.

Mr. E. J. Hunt, of the firm of Chance and Hunt, Oldbury, has been appointed a Justice of the Peace for the County of Worcestershire.

CORRESPONDENCE

"BAYER 205"

Sir,—In the editorial of the third number of this year, which I have only just seen, you mentioned "Bayer 205," which, from your remarks, had evidently been reviewed in *The Times*, and there described as a compound of carbon, hydrogen, etc., without indication of constitution. You qualified this latter by saying that so far nothing more seemed to be known in this country, and while this is quite true, an indication of the type of compound was given as



in an article in the issue of September 23, 1922, of the *British Medical Journal*, page 568. It was there suggested that Bayer 205 was a derivative of this. You may, of course, have information later to the contrary, but with the exception of this I have seen no detailed account at all. A short historical survey is included, and an article covering, in a general way, compounds of specific action (including Bayer 205) is given on p. 807 of the same Journal.

This may, I hope, be of interest to your readers, as it is an extremely important branch of the subject, and if any other references are available they would be appreciated.—I am, Sir, etc.,

Eric Dow

Physiological Institute,
University of Glasgow
February 4, 1924

INDUSTRIAL AND MEDICAL RESEARCH.

Sir,—In my article, "The Epilation of Skins," which you were good enough to publish last week, I mention that some of the experiments might be of service to cancer research. It may interest your readers to explain this connexion, as it shows how industrial research can help medical research as well as *vice versa*. It is practically certain that cell-proliferation leading to a growth is immediately caused by nitrogenous bases which contain the N—C=N grouping. These bases are produced in the living body by chronic injury (irritation) in a tissue and probably by bacterial invasion of the site. The intermediate stages were not realised fully until the leather research was made in the tannery. Here the great importance of the two enzymes became apparent. The amino substances are produced by a histo-protease set free by the injury and by a parasite-protease as a result of the infection. The importance of the position of equilibrium was also revealed by the researches in the tannery (which were completed in 1919), and cases of cancer are being treated experimentally on this principle.—I am, Sir, etc.,

H. C. Ross

113, Mount Pleasant, Liverpool
January 30, 1924.

LEAD SMELTING IN GREAT BRITAIN

Sir,—Mr. C. A. Klein, in his review of J. A. Smythe's "Lead, Its Occurrence in Nature," etc., states that in this country the lead produced by smelting does not exceed one-fifth of the total quantity of metal used for all purposes. Surely this figure is much too high. For a good many years before the war our output of lead from British concentrates was roughly 20,000 tons a year, and our imports 220,000 tons; allowing for imported ores and exported lead we may take it that one-tenth is a more correct figure than one-fifth. In 1922 the figure was about one-twentieth, but this was a year of great depression in home mining, and the returns must be considered abnormal.—I am, Sir, etc.,

H. L. Terry

36, Brook Road, Fallowfield,
Manchester
February 4, 1924

HIGH PRICE OF REPRINTS

Sir,—In reviewing reprints of two General Discussions recently held by the Faraday Society, your reviewers, while approving of the policy of the Society in making these Reports generally available, expressed the hope that their high price would not impede their circulation among scientific workers. The kind reception accorded by you to these Reports is greatly appreciated by the Council of the Society, but may I be permitted to say a word in explanation of their high price?

The price of any book is largely determined by its circulation. In the case of a Society like the Faraday Society, which, in spite of its small membership, publishes a large amount of scientific material, the price of the *Transactions* is necessarily high. Reprints from the *Transactions* must be priced accordingly, lest non-members who purchase the reprints should receive them on better terms than members through whose subscriptions publication is rendered possible.

It is unnecessary to say that we desire a wide publicity for our Reports of General Discussions, but they can be produced at a cheaper rate only if the Society receives a far greater measure of support from British chemists and physicists than is at present the case.—I am, Sir, etc.,

Robert Robertson,
President, Faraday Society

10, Essex Street, Strand, W.C.
February 5, 1924

We regret to announce the death of Mr. W. E. Moulsdale, chairman of Cope Brothers, Ltd., tobacco manufacturers, who had been a member of this Society since 1917. Mr. Moulsdale was an engineer by profession, and was interested in educational work.

PERSONAL AND OTHER NOTES

On February 1, a bust of Prof. H. B. Dixon, F.R.S., was unveiled in the Chemical Theatre of Manchester University to commemorate his valued service to the University from 1886 to 1922. After the Vice-Chancellor, Sir H. Miers, had paid tributes to Prof. Dixon as scientist, man of letters and mountaineer, the bust was unveiled by Dr. H. G. Colman, one of Prof. Dixon's early students, many colleagues and past students being present. In the course of his reply, Prof. Dixon said his aim had been to foster research and not allow Manchester to fall behind the German schools of chemistry.

Mr. S. Stewart, F.I.C., has recently retired after over 27 years' service as works chemist to Messrs. Michael Nairn & Co., Kirkcaldy. To mark the occasion, the directors and staff gave Mr. Stewart a handsome present and a letter expressing the general goodwill which he has earned.

Sir Richard Glazebrook, F.R.S., has been appointed by the Chancellor of Cambridge University a member of the Court of the University of Liverpool.

G. W. Jones, assistant gas chemist to the U.S. Bureau of Mines, has been promoted to the post of associate chemical technologist to carry out research on explosives. He succeeds Dr. J. L. Sherrick, who has retired to take up the manufacture of gelatin.

The Council of the Institution of Electrical Engineers have made the third award of the Faraday Medal to Dr. S. Z. de Ferranti, a past President of the Institution. The Faraday Medal is awarded by the Council of the Institution not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering, or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution. Dr. Ferranti was a pioneer in the supply of electricity, and his early grasp of the fundamental principles of electric power supply have had a profound influence, not only in this country, but all over the world.

The scheme for fellowships in chemical science in memory of the late Sir William Ramsay has now come to full fruition. At the present time sixteen fellowships for chemical science are being held in the Universities or Colleges of the United Kingdom. The awards for the present session are as follows, the University or College which has been selected by the fellow for his research appearing after the name in each case:—British: Dr. Samuel Coffey (University College, London); Dr. R. W. Lunt (University College, London); and Dr. A. F. Titley (Oxford); Glasgow: Mr. J. A. Mair (Glasgow), and Mr. T. S. Stevens (Glasgow); Canadian: Dr. E. H. Boomer (Cambridge); Danish: Mr. K. Hejendahl (Liverpool); Dutch: Dr. C. F. van Duin (St. Andrew's), and Dr. T. Kalff (Liverpool); French: Dr. H. Weiss (Royal Institution, London); Italian: Dr. A. Nasini (Cambridge); Japanese: Dr. N. Kameyama (University College, London); Norwegian: Mr. Gunnar Weidemann (Cambridge); Spanish: Dr. Miguel Crespi (University College, London); Swedish: Mr. A. W. Bernton (Oxford), and Dr. J. Lublin (Cambridge). The total value of the annual amount of the fellowships that is awarded is £5007, of which £3500 is provided by grants from Dominion and foreign sources.

CANADA

New Artificial Silk Plant

It is announced that Courtaulds, Ltd., has purchased 240 acres of land near the St. Lawrence river, Ontario, as a site for a new artificial silk plant. Three plants belonging to the firm are already working in the United States, but the Canadian plant will have advantages in the export trade that factories in the neighbouring country do not possess.

BRITISH INDIA

Indian Mineral Output in 1922

The following table has been drawn up from a report on the mineral production of India during 1922 by the Director of the Geological Survey, India:—

	Amount	1921	1922
Chromite	tons	22,777	34,762
Coal	,,	19,010,986	19,302,947
Copper	,,	30,764	23,089
Diamonds	carats	171·39	126·1
Gold	oz.	433,722·59	438,015·04
Graphite	tons	—	25
Iron	,,	625,274	942,084
Jadeite	cwts.	7,724·7	3,815
Lead	tons	39,214	33,717
Magnesite	,,	19,000	20,000
Manganese	,,	474,401	679,286
Mica	cwts.	31,570·1	32,488
Monazite	tons	125	1260
Petroleum	gall.	299,500,000	305,683,227
Ruby, Sapphire Spinel	carats	231,160	193,915
Salt	tons	1,653,898·2	1,533,679
Saltpetre	,,	11,672·9	15,893·7
Silver	oz.	4,205,584	3,555,021
Tin ore	tons	1874·7	1701·6
Tungsten	,,	943	898·3
Zinc	,,	18,061	4000
Alum	cwts.	6632	3380
Asbestos	tons	242	—
Barytes	,,	2392·2	1691
Bauxite	,,	3987	1999
Clay	,,	104,748	199,266
Fuller's Earth ..	,,	13,539	2807
Gypsum	,,	40,645·5	33,801
Ilmenite	,,	400	—
Ochre	,,	6702	5812·7
Soda	,,	28	10
Steatite	,,	906	2010
Zircon	,,	160	—

The number of mineral concessions granted during 1922 amounted to 672, as against 651 in 1921; of these, 562 were prospecting licences and 110 were mining leases.—(*Ind. Tr. J., Jan.* 3, 1924.)

FRANCE

National Fuel

The Ministry of Agriculture has issued a circular stating that the name of "National Fuel" can be applied only to mixtures of hydrocarbons and alcohol containing for each 100 volumes of hydrocarbon more than 95, and less than 105, volumes of alcohol. The mixture must also possess certain physical properties which are defined in the circular.

Funds for Laboratories

The Chamber of Commerce of Lyons, wishing to celebrate the centenary of Pasteur, has opened a fund for the benefit of the laboratories of Lyons, and already 680,000 francs has been contributed. Each year a part of the capital, amounting to about 120,000 francs, will be distributed amongst a certain number of the laboratories in Lyons, and the scientific directors have been invited to communicate each year what results have been obtained.

Salt and Potash Production

The production of salt has risen from 90,530 tons in October, to 100,768 t. in November. The French potash mines produced 94,775 t. of potash, equivalent to 22,747 t. of K_2O, and consisting of crude salts (12 to 16 per cent.), 42,480 t.; manure salts (20 to 22 per cent.), 25,254 t.; manure salts (30 to 40 per cent.), 16,039 t.; chloride (over 50 per cent.), 11,002 t.

Technical Conference on Ceramics

A Conference of Ceramic Industries will be held in May in Paris. As with the meeting last year, the conference will discuss questions such as the firing of ceramic products in furnaces with natural or induced draught, natural and artificial drying, and the best power systems for ceramic industry.

UNITED STATES

Expansion in the Glass Industry

According to a recent article (*Chem. & Met. Eng., Dec.* 31, 1923), the glass industry in the United States will be considerably expanded during 1924, as over $18,000,000 is to be expended on extensions and other improvements. New plants are to be erected by the Libby-Owens Glass Co., at Ohio, by the National Plate Glass Co., at Ottawa, Ill., and at Blairsville, Pa., and improvements and extensions are to be made by the Clarksburg Glass Co., the Wheeling Glass Manufacturing Co., W.Va., the Westmoreland Specialty Glass Co., Pa., the Weston Glass Co., W.Va., and the Sneath Glass Co., Ind.

GENERAL

Nitrogen Fixation in Czechoslovakia

A Bill is shortly to be laid before the Czechoslovakian Parliament, to encourage the nitrogen-fixation and fertiliser industries, either by a reduction of, or exemption from, taxes. Germany has hitherto been the chief source of supply of nitrogenous fertilisers, and it is proposed to develop the Czechoslovakian industries to ensure home supplies, as deliveries from Germany are obtained with difficulty.

Metallurgy in Belgium

During December 40 blast furnaces were alight in Belgium, there being no increase in number, compared with November. The production was: cast iron, 209,350 metric tons; raw steel, 206,700 t.; castings, 5950 t.; finished steel, 189,340 t.; finished iron, 16,640 t.; zinc, 13,790 t.

The output of coal fell from 2,088,810 tons in November, to 1,985,810 t. in December, but coke production rose from 369,100 t. to 372,150 t.

REVIEWS

Metals and Metallic Compounds. By U. R. Evans, M.A. *Vol. I. Introduction, Metallography, Electro-Chemistry. Pp. xii+468. Price* 21*s. Vol. II. Metals of the 'A' Groups. Pp. xi+396. Price* 18*s. Vol. III. The Transition Elements. Pp. xii+270. Price* 14*s. Vol. IV. Metals of the 'B' Groups. Pp. xii+350. Price* 18*s. London: E. Arnold & Co.,* 1923.

The author's intention in writing this book was not to conform to the traditional practice of giving long "catalogues of salts and empirical accounts of metallurgical processes," no doubt necessary in books of reference, but to present the subject in a form suitable for continuous reading. His aim is to take advantage of recent fruitful research work in metallography, crystallography, electrochemistry, colloid chemistry, and geo-chemistry to approach the subject of metals in a new spirit, to correlate cause and effect and to introduce such theoretical views as will serve to connect the known facts in an ordered sequence.

The first volume is of a generalised character, beginning with an introduction of 135 pages in which the author has given, in condensed and non-mathematical form, the elementary principles of general chemistry, physics and geology; a knowledge of which, in the body of the book, the reader is assumed to possess. This introduction, admirably clear and concise and especially valuable to those whose memory needs refreshing or who, for some reason or other, are not sufficiently familiar with the most recent advances of the subject, closes with a chapter entitled "Some general considerations involved in metallurgy," wherein the author touches upon such essentially practical matters as the preliminary treatment of ores, crushing, grinding, concentration by gravity, magnetism and flotation, etc., in each case defining the objects in view and the theory of the operation. The body of volume I. is divided into two parts "The Study of the Ionic State" (Electro-chemistry). The latter includes chapters on the colloidal state in metals and metallic compounds, electro-deposition, the corrosion of metals and radio-activity.

Volumes II, III, and IV deal with the individual metals, the space devoted to each being divided into three main sections. In the first, the pure chemistry of the metal and its compounds are discussed and a summary is given of the methods of analysis. The second section deals shortly with the terrestrial occurrence of the metal in question, and the third section is of a technical character, dealing with the metallurgy, technology and uses.

The author has covered a prodigiously wide field and, on the whole, he is to be congratulated on the judgment shown in the selection and condensation of his matter. The book is well printed, copious references are given throughout and author and subject indices are provided at the end of each volume.

I.—PERFUMES AND SYNTHETICS WITH SPECIAL REFERENCE TO SYNTHETICS. *By* W. A. POUCHER. *Pp.* xi+462. *London: Chapman and Hall, Ltd.,* 1923. *Price* 21s.

II.—THE PREPARATION OF PERFUMES AND COSMETICS. *By* J. P. DURVELLE. *Translated from the fourth French edition, by* E. J. PARRY, B.Sc. *Pp.* viii+420. *London: Scott, Greenwood and Son,* 1923. *Price* 21s.

III.—PERFUMES AND COSMETICS: THEIR PREPARATION AND MANUFACTURE. *By* G. W. ASKINSON. *Pp.* xiii+302. *London: Crosby, Lockwood and Son,* 1923. *Price* 30s.

The great fascination of the study of perfumes has led many chemists to carry out exhaustive investigations on the subject, so that the art of the perfumer is gradually acquiring a more scientific basis. It will be of interest to consider the books under review together, as they can be taken to represent standard practice in France, the United States and England.

I. Mr. Poucher has divided his subject into three parts, of which the first is a dictionary of the more important raw materials of the "chemist-perfumer." In Part II, chapters are devoted to the production of natural perfumes, the fixation of perfumes, and accounts of flower perfumes, fancy perfumes and toilet waters. Part III treats of a wide variety of cosmetics. Throughout the book, formulæ are plentiful and there are excellent illustrations. The new synthetic perfumes are treated at length, and the book, with its practical bias and freedom from excess of scientific detail, will undoubtedly be a valuable aid to the practical perfumer. Where so much is good it is disappointing to find that the wording of the scientific matter is too often loose and unsatisfactory. Apart from this, the work, which is handsomely produced and well printed, can be safely recommended as a practical guide.

II. In this book, a translation of the latest edition of the well-known work originally published under the title "Nouveau Guide du Parfumeur," raw materials are discussed in the first 87 pages, and the remainder of the work is devoted to the manufacture of perfumed products. The aim is a practical one and numerous formulæ are given, the chemical treatment being clear and adequate. By the use of concise statements, a surprisingly large amount of information, scientific and practical, is given, and the book everywhere reveals the thorough acquaintance of both author and translator with the perfumery industry. A commendable feature is the frank discussion of the value of cherished ingredients in various toilet preparations, some useless, some dangerous, and this should do good. An excellent work.

III. This book opens with a short history of perfumery, and after discussing the chief natural perfumes it treats of chemicals used in perfumery, methods of provided and the manufacture of perfumes and cosmetics. Some concluding chapters are contributed by various authors, who give advice on the place of synthetics in perfumery, the use of fixatives, storage and ageing, soap perfuming, and the advertisement and marketing of the finished preparations. Formulæ that have "withstood the tests of use" are given in quantity, and information regarding the source and character of perfumery materials is provided to enable the user to make a suitable choice. The artistry required in the preparation of perfumes is constantly kept before the reader, and there are many useful practical hints. The work has already reached its fifth edition, and it should prove both stimulating and helpful to those interested in the industry.

TEXTILINDUSTRIE. *By* PROF. P. KRAIS. *Technische Fortschrittsberichte. Fortschritte der Chem. Technologie in einzeldarstellungen, edited by* PROF. B. RASSOW. *Part III. Pp.* 156. *Dresden and Leipzig: Theodor Steinkopff,* 1924. *Price,* 4.50 *marks.*

This volume is one of a series of monographs dealing with progress in different departments of chemical technology, and such monographs are welcome because they provide halting places in the march of technical science, and opportunities of reflecting on the effect of different researches on industrial developments.

In this country important research on textiles is being carried out by research associations in Manchester, Leeds and Belfast; some of the results being published in the *Journal of the Textile Institute,* and abstracted in this *Journal.* In the volume under review some of these researches receive attention. In writing such a monograph, however, the difficulty lies in choosing a suitable time for considering past work, and this point is emphasised in the chapter on mercerisation, wherein many important recent researches are not mentioned, and this omission leaves the chapter without interest. Also in this chapter certain industrial developments are mentioned, some of which are of interest, and others of little interest, their mention only serving to indicate that the author of the volume is not thoroughly in touch with industrial changes. In other parts of the book it is also noticed that what one might call a commercial sense of proportion is lacking.

The constitution, morphology, strength, lustre, spensing qualities and other properties of textile fibres are discussed. German researches and patents receive full consideration; those of other countries not such full treatment. Ten pages are devoted to progress in artificial silk manufacture, 48 pages to dyeing, 7 to printing, and 15 to finishing.

The chapter on bleaching is of little interest. The use of warm hypochlorite solutions, the occurrence of chloramines during the bleaching of cotton goods, the preparation of hypochlorite solutions by electrolyses, and the bleaching actions of perborates and peroxides are discussed at length, whereas these subjects are of little interest to those technologists engaged in the bleaching industry.

The volume is interesting to read and ought to repay the time spent on it; its appearance suggests to your reviewer that after ten volumes of *Annual Reports* issued by this Society have appeared, monographs should be prepared for some sections, dealing with the progress during the ten years' period. For instance, the excellent annual *résumés* of the literature dealing with fibres would yield a useful monograph dealing with the ten years' period.

S. H. HIGGINS

CHEMISCHE GRUNDBEGRIFFE. *By* PROF. A. BENRATH. *Translated by* JETHRO BITHELL, M.A. *Bilingual Series. Edited by* J. E. MANSION. *Pp.* 80+80. *London: George G. Harrap & Co., Ltd.*, 1924. *Price* 2*s*.

This neatly printed little book is an adaptation of the plan, long familiar to students of the classics, of printing text on one page with the translation on the opposite page. Purists will doubtless take exception to such a method of acquiring a knowledge of a foreign language, but used in conjunction, as the author advises, with a grammar, the book will not only enable the student to widen his German vocabulary with more ease, but will hlep him to attain to that psychological acquaintance which is essential before understanding of any foreign tongue can even approach completeness. In the present volume, Prof. Benrath's interesting essay on the fundamental ideas of chemistry is used as text, and Mr. Bithell provides the translation so that the chemist is provided with interest as well as instruction. The translation appears to be reasonably well done, though occasional phrases such as "Brown's motion," "The Laws of Gas," seem a little strange. It is to be hoped that this "Bilingual Series" will encourage scientists to study other languages than their own, if not for the acquisition of new knowledge, certainly for the acquisition of that broader outlook on human affairs which is essential to make the "full man."

COMPANY NEWS

JOHN KNIGHT, LTD.

The report for the year ended November 30 last shows a net profit of £147,166, compared with £151,316 in the previous year. With £68,017 brought in, £215,183 becomes available, and the directors again propose to pay a dividend of 30 per cent. for the year on the ordinary shares, carrying forward £69,183.

JURGENS, LTD.

For the six months to December 31 last, a dividend is announced of 7 per cent., less tax on the 7 per cent. (guaranteed) cumulative preference shares.

BORAX CONSOLIDATED, LTD.

It is proposed to pay a final dividend of 1s. 6d. per share ($7\frac{1}{2}$ per cent.), and a bonus of 6d. per share ($2\frac{1}{2}$ per cent.) less tax, on the deferred ordinary shares, making 15 per cent. for the year ended September 30, 1923.

MOND NICKEL CO., LTD.

An interim dividend of 5 per cent., less tax, has been declared on the ordinary shares, and of $3\frac{1}{2}$ per cent. less tax on the preference shares.

MAGADI SODA CO., LTD.

At the extraordinary general meeting held on January 28 it was found impossible to carry the scheme for the reconstruction of the company. The result of a poll on the scheme will be declared later.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The comparatively healthy state of the Chemical market continues, and business is very steady with few outstanding features attracting attention. Prices are firm.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw. Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	$5\frac{1}{4}$d. per lb.
Potass. Chlorate	3d.—$3\frac{1}{4}$d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Good business continues.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

The demand for rubber chemicals remains somewhat slow, and values are slightly lower.

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	$5\frac{1}{4}$d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide	4s. per lb.

Carbon Bisulphide .. £24—£26 10s. per ton according to quantity.

Carbon Black .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.

Carbon Tetrachloride .. £55 per ton, drums free.

Chromium Oxide .. 1s. 2d. per lb.

Indiarubber Substitutes, White and Dark .. 4d.—6½d. per lb. Fairly brisk demand.

Lamp Black .. 40s. per cwt., barrels free.

Lead Hyposulphite .. 7½d. per lb.

Lithopone .. £22 10s. per ton.

Mineral Rubber "Rubpron" .. £15 10s. per ton f.o.r. London.

Sulphur .. £10—£12 per ton, according to quality.

Thiocarbanilide .. 2s. 9d. per lb.

Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.

Zinc Sulphide .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade and there appears a more healthy prospect in the charcoal market.

Acetate of Lime—

Brown .. £14 10s. per ton d/d. Demand active.

Grey .. £22 per ton.

Liquor .. 9d. per gall. 32° Tw.

Charcoal .. £7 5s.—£9 per ton, according to grade and locality. Market quiet.

Iron Liquor .. 1s. 7d. per gall. 32° Tw.
1s. 2d. " " 24° Tw.

Red Liquor .. 10d.—1s. per gall. 14/15° Tw.

Wood Creosote .. 2s. 7d. per gall. Unrefined.

Wood Naphtha—

Miscible .. 5s. 6d. per gall. 60% O.P. Dull market.

Solvent .. 5s. 6d. per gall. 40% O.P. Dull market.

Wood Tar .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.

Brown Sugar of Lead .. £42 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—

Crystals .. 8½d. per lb. Some business passing at lower prices.

Crude 60's .. 2s.—2s. 3d. per gall. Little business passing. Market weaker in sympathy with crystals.

Acid Cresylic, 97/99 .. 1s. 11d.—2s. 2d. per gall. Steady business.

Pale 95% .. 1s. 10d.—2s. 1d. per gall. Good demand.

Dark .. 1s. 7d.—1s. 11d. per gall. Steady business.

Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—

Strained .. 9d.—10d. per gall. Very quiet.

Unstrained .. 8d.—9d. per gall.

Benzole—

Crude 65's .. 10½d.—1s. per gall. ex works in tank wagons.

Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.

Pure .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. 1s. 3d.—1s. 4d. per gall.

Pure .. 1s. 8d.—1s. 10d. per gall.

Xylol .. 2s. 3d. per gall.

Creosote—

Cresylic 20/24% .. 11½d. per gall. Firm. Fair business passing.

Middle Oil ..
Heavy ..
Standard Specification
} 9d.—10d. per gall. according to grade and district. Market very firm. Demand good.

Naphtha—

Solvent 90/160 .. 1s. 0½d.—1s. 2d. per gall.
Solvent 90/190 .. 1s. 1d.—1s. 3d. per gall.
} rather more business.

Naphthalene Crude—

Drained Creosote Salts £7 10s.—£8 per ton. Demand maintained.

Whizzed or hot pressed £10—£14 per ton. Quiet and weak.

Naphthalene—

Crystals .. £18 per ton.

Flaked .. £18 per ton.

Pitch, medium soft .. 80s.—85s. per ton. Nominal. No sellers.

Pyridine—90/140 .. 16s.—17s. per gall. More stable with fair business.

Heavy .. 11s.—12s. Firmer with better demand.

INTERMEDIATES AND DYES

Business in dyestuffs has improved appreciably since the holidays. Prices are very firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 9d. per lb.

Acid H. .. 4s. 6d. per lb. 100% basis d/d.

Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.

Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.

Acid Salicylic, tech. .. 1s. 6d. per lb. Better demand.

Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.

Aluminium Chloride, anhyd. .. 1s. per lb. d/d.

Aniline Oil .. 8½d. per lb. naked at works.

Aniline Salts .. 9d. per lb. naked at works.

Antimony Pentachloride 1s. per lb. d/d.

Benzidine Base .. 4s. 8d. per lb. 100% basis d/d.

Benzyl Chloride 95% .. 1s. 3d. per lb.

p-Chlorphenol .. 4s. 3d. per lb. d/d.

p-Chloraniline .. 3s. per lb. 100% basis.

o-Cresol 29/31° C. .. 5½d.—6d. per lb. Demand quiet.

m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Market quiet.

p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Market quiet.

Dichloraniline .. 2s. 2d. per lb.

Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.

p-Dichlorbenzol .. £75 per ton.

Diethylaniline .. 5s. per lb. d/d., packages extra, returnable.

Dimethyaniline .. 2s. 5d. per lb. d/d. Drums extra.

Dinitrobenzene .. 9d. per lb. naked at works.

Dinitrochlorbenzol .. £82 per ton d/d.

Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.

66/68° C. 1s. 2d. per lb. naked at works.

Diphenylamine .. 3s. 3d. per lb. d/d.

Monochlorbenzol .. £63 per ton.

β-Naphthol .. 1s. 1d. per lb. d/d.

α-Naphthylamine .. 1s. 5d. per lb. d/d.

β-Naphthylamine .. 4s. per lb. d/d.

m-Nitraniline .. 5s. 3d. per lb. d/d.

p-Nitraniline .. 2s. 5d. per lb. d/d.

Nitrobenzene .. 5¼d.—5½d. per lb. naked at works.

o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.

Nitronaphthalene .. 11½d. per lb. d/d.

p-Nitrophenol .. 1s. 9d. per lb. 100% basis d/d.

[illegible] .. 4s. 6d. per lb. 100% basis

m-Phenylene Diamine	4s. 6d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. per lb. 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 7d. per lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market is stagnant as buyers are holding off in view of the great uncertainty as to the future of pharmaceutical chemicals.

Acid, Acetic 80% B.P.	£50 per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 9d. per lb. Steady demand.
Acid, Benzoic	Commercial acid dearer at 2s. 9d. per lb. B.P. quality remains unobtainable.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	18s.—20s. per lb.
Acid, Citric	1s. 5½d. per lb., less 5% for ton lots. Demand fair.
Acid, Gallic	3s. per lb. for pure crystal. More inquiry.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	2s. 4d.—2s. 6d. per lb. Market dull.
Acid, Tannic	3s. 3d. per lb. for B.P. quality.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Fair demand.
Amidol	9s. per lb. d/d.
Acetanilide	3s. per lb. No inquiry.
Amidopyrin	14s. per lb. Demand negligible.
Ammon. Benzoate	3s. 9d. per lb. Much cheaper.
Ammon. Carbonate B.P.	£35 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make. Market neglected.
Barbitone	17s. per lb.
Benzonaphthol	5s. 6d. per lb. Supplies scarce. Some dealers quote more.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9½d.—11d. } Foreign market somewhat easier.
Sodium	9½d.—11d. }
Ammonium	11d.—1s. }
Calcium Lactate	2s. 9d. per lb. for best English make. Market firmer in view of shrinkage of imports.
Chloral Hydrate	4s. per lb. Weak.
Chloroform	2s. per lb. for cwt. lots.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	13s. per lb. for small stocks available. Slightly weaker.
Hexamine	3s. 9d.—4s. per lb. for foreign makes.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£72 10s. per ton, less 2½%.
Heavy Commercial	£27 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst.	56s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Prices reduced.
Red oxide	4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	3s.—3s. 1d. „
White precip.	4s. 1d.—4s. 2d. „
Calomel	3s. 5d.—3s. 6d. „
Methyl Acetanilide	20s. per lb.
Methyl Salicylate	2s. 11d. per lb. for carboys. Slightly firmer.
Methyl Sulphonal	21s. per lb.
Methylene-di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 7d. per lb.
Phenacetin	7s. 3d. per lb. Orders falling off.
Phenazone	8s. per lb.
Phenolphthalein	8s. per lb. Price shaded for quantity. Ample supplies.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s.—90s. per cwt., less 2½%. Demand improving.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. 3d. per lb.
Salol	3s. 9d.—4s. per lb. Slightly firmer.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb.
Sod. Citrate, B.P.C., 1923	1s. 9d.— per lb., according to quantit.
Sod. Hyposulphite—Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	87s. 6d. per cwt. Market quiet.
Sod. Salicylate	Powder 2s. 10d.—2s. 11d. per lb., Crystal at 2s. 11d.—3s. per lb.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	18s. 6d. per lb.
Tartar Emetic	1s. 4d. per lb.
Thymol	13s. 6d.—13s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.	
Aubepine	.. 13s. 6d. ,,	
Amyl Acetate ..	.. 3s. ,,	
Amyl Butyrate ..	.. 7s. 3d. ,,	
Amyl Salicylate ..	.. 3s. 6d. ,,	
Anethol (M.P. 21/22° C.)	3s. 9d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 3d. ,,	
Benzyl Alcohol free from Chlorine ..	.. 3s. 3d. ,,	
Benzaldehyde free from Chlorine ..	.. 3s. 3d. ,,	
Benzyl Benzoate ..	.. 3s. 9d. ,,	
Cinnamic Aldehyde Natural ..	.. 18s. 6d. ,,	Cheaper.
Coumarin ..	.. 21s. ,,	
Citronellol ..	.. 19s. ,,	
Citral	.. 10s. ,,	
Ethyl Cinnamate ..	.. 10s. ,,	
Ethyl Phthalate ..	.. 3s. 9d. ,,	
Eugenol	.. 11s. ,,	
Geraniol (Palmarosa)	.. 37s. 6d. ,,	
Geraniol	.. 10s.—17s. 6d. per lb.	
Heliotropine ..	.. 8s. 6d. per lb.	
Iso Eugenol	.. 15s. 9d. ,,	
Linalol ex Bois de Rose ..	20s. ,,	
Linalyl Acetate ..	.. 20s. ,,	
Methyl Anthranilate	.. 8s. 6d. ,,	
Methyl Benzoate ..	.. 6s. ,,	
Musk Ambrette ..	.. 52s. 6d. ,,	
Musk Xylol	.. 19s. ,,	
Nerolin	.. 4s. ,,	
Phenyl Ethyl Acetate	.. 10s. ,,	
Phenyl Ethyl Alcohol	.. 16s. ,,	
Rhodinol	.. 65s. ,,	
Safrol	.. 1s. 10d. ,,	
Terpineol	.. 2s. 6d. ,,	
Vanillin	.. 26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. ..	.. 14s. 6d. per lb.	
Anise Oil	.. 1s. 11d. ,,	
Bergamot Oil ..	.. 13s. 9d. ,,	
Bourbon Geranium Oil	.. 32s. 6d. ,,	
Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil, Java	.. 9s. 4½d. per lb.	
Cinnamon Oil, Leaf	.. 5½d. per oz.	
Cassia Oil, 80/85%	.. 10s. per lb.	
Citronella Oil— Java 85/90% ..	.. 4s. 7½d. ,,	
Ceylon	.. 3s. 9d. ,,	Cheaper
Clove Oil	.. 9s. 3d. ,,	
Eucalyptus Oil 70/75%	.. 2s. 4½d. per lb.	
Lavender Oil— French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil ..	.. 3s. ,,	
Lemongrass Oil ..	.. 2½d. per oz.	
Orange Oil, Sweet	.. 12s. 6d. per lb.	
Otto of Rose Oil— Bulgarian ..	.. 34s. per oz.	
Anatolian	.. 26s. per oz.	
Palma Rosa Oil ..	.. 20s. per lb.	Cheaper.
Peppermint Oil— English ..	.. 70s. per lb.	
Wayne County ..	.. 16s. 6d. per lb.	
Japanese	.. 13s. 9d. per lb.	Advanced.
Pettigrain Oil ..	.. 9s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications

Backhouse and Samuelson. Apparatus for mixing pulverulent and granular materials. 1129. Jan. 15.

De Laval Chadburn Co., and Johnstone. 1868. *See* XIX.

Duckham and others. 1413. *See* II.

Gray. Dehydration process. 1497. Jan. 18.

Hurst. Separators for liquids. 1727. Jan. 22.

Lamb. Catalysts, and process of producing same. 1777. Jan. 22.

Mortimer. Pressure apparatus for filtering etc. liquids. 971. Jan. 14.

Pehrson and Pehrson. Rotary furnaces. 1748. Jan. 22.

Plauson's (Parent Co.), Ltd. (Plauson). Production of finely-divided materials. 1741. Jan. 22.

Complete Specifications Accepted

24,743 (1922). Toogood, and Dempster and Sons. Regenerator furnaces. (209,458.) Jan. 23.

27,288 (1922). Fothergill. Evaporators. (209,475.) Jan. 23.

28,977 (1922). Seaman, and Brinjes and Goodwin, Ltd. Grinding, crushing, mixing, and like mills. (209,857.) Jan. 30.

31,373 (1922). Meister, Lucius, u. Brüning. Apparatus for absorbing gases or vapours by means of charcoal. (191,005.) Jan. 30.

33,380 (1922). Holmes. Pulverising machines. (209,577.) Jan. 23.

2231 (1923). Candy. Filters. (209,947.) Jan. 30.

2932 (1923). Rialland. Separating mixed liquids of different volatility. (193,030.) Jan. 23.

4843 (1923). Akt. de Norske Saltverker. Treatment of solutions for the precipitation of solid substances therefrom. (195,597.) Jan. 23.

18,473 (1923). Westenholz and Nyrop. Centrifugal machine for producing emulsions, colloidal solutions, etc. (210,023.) Jan. 30.

21,092 (1923). Gelder. Grinding and pulverising machine. (210,027.) Jan. 30.

II.—FUEL; GAS; DESTRUCTIVE DISTILLATION; MINERAL OILS; LIGHTING

Applications

Collin u. Co. Gas-reversing devices for regenerative coke ovens. 1193. Jan. 15. (Ger., 8.2.23.)

Coninck. Combustion of solid fuel. 1308. Jan. 16. (Fr., 26.1.23.)

Davidson and Lindsay. Process of oil refining. 1870. Jan. 23.

Dicker (Wallace). Production of carbon and carboniferous products. 2089. Jan. 25.

Donald. Drying peats etc. 1140 and 1891. Jan. 15 and 23.

Duckham, Rider, Watts, and Thermal Industrial and Chemical Research Co. Heat-treatment of materials for distilling, drying, or carbonising them. 1413. Jan. 17.

Fuchs. Fractional condensation of mineral oils etc. 1099. Jan. 14. (Austria, 13.1.23.)

Kaisler. Fuel for internal-combustion engines. 1172. Jan. 15.

Leggett. Apparatus for washing gas etc. 2142. Jan. 26.

Malone. 1422. *See* XXIII.

Quick. Refining lubricating etc. oils. 1267. Jan. 16.

Stinnes-Riebeck Montan u. Oelwerke. 1794. *See* III.

COMPLETE SPECIFICATIONS ACCEPTED

24,340 (1922). Alexander. Motor spirit for use in internal-combustion engines. (209,453.) Jan. 23.

25,731 (1922). Sutcliffe. Briquetting or agglomerating fuel etc. (209,794.) Jan. 30.

29,241 (1922). White. Low-temperature carbonisation. (192,040.) Jan. 30.

30,919 (1922). Wood. Gas - producers. (189,767.) Jan. 30.

2755 (1923.) Baskerville. Producer for gasifying bituminous and other fuels. (209,955.) Jan. 30.

4261 (1923). Trent Process Corp. Production of coked, semi-coked, or fused fuel. (193,061.) Jan. 23.

III.—TAR AND TAR PRODUCTS

APPLICATION

Stinnes-Riebeck Montan- u. Oelwerke A.-G. Separation of benzol or benzine from mixture containing dilute alcohol. 1794. Jan. 22. (Ger., 22.1.23.)

IV.—COLOURING MATTERS AND DYES

APPLICATIONS

Farbenfabr. vorm. F. Bayer u. Co. 1306. *See* XIII.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of azo dyestuffs. 1505. Jan. 18. (Ger., 18.1.23.)

Hooley, Thomas, and Scottish Dyes, Ltd. Manufacture of hydroxyanthraquinone derivatives. 2148. Jan. 26.

COMPLETE SPECIFICATIONS ACCEPTED

31,406 (1922). Holliday and Co., and Stokes. Azo colouring matter of the pyrazolone series. (209,547.) Jan. 23.

31,413 and 31,427 (1923). Holliday and Co., and Clayton. Yellow colouring matters of the pyrazolone series. (209,885 and 209,887.) Jan. 30.

740 (1923). Pigments Ges., and Detsinyi. Production of a dye for hair. (209,937.) Jan. 30.

12,469 (1923.) Soc. Chem. Ind. Basle. Manufacture of dyestuffs of indigo tint. (210,006.) Jan. 30.

24,609 (1923). Thomas, and Scottish Dyes, Ltd. Chlorination of hydroxyanthraquinones. (209,694.) Jan. 23.

30,645 (1923). Meister, Lucius, u. Brüning. Chlorination of benzene. (208,155.) Jan. 30.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER

APPLICATIONS

British Burmah Petroleum Co., and Dickie. Manufacture of artificial waterproof board. 1280. Jan. 16.

Chem. Fabr. Griesheim-Elektron, and Wiss. Obtaining fibre from plants. 1566. Jan. 19.

Cook and Co., and Stott. Treatment of fibrous materials. 1432. Jan. 18.

Downs. Extraction of oil or grease from textile fabrics. 1900. Jan. 24.

Harbens, Ltd., Leon, and Sharrat. Manufacture of artificial silk threads etc. 2082. Jan. 25.

COMPLETE SPECIFICATION ACCEPTED

22,065 (1923). Marx. Manufacture of paper, pulp, board, etc. (209,693.) Jan. 23.

VI.—BLEACHING; DYEING: PRINTING; FINISHING

APPLICATIONS

Boardman, Hunt, and Hunt an[illegible]rop. Apparatus for treating wool etc. with dye etc. [illegible] Jan. 19.

Boardman, and Hunt a[illegible]rop. Apparatus for dyeing and scouring yarn etc. [illegible] Jan. 19.

Lithgow. Dyeing-jigs etc. 1230. Jan. 16.

Schumacher. Dyeing cops. 2084. Jan. 25. (Ger., 2.2.23.)

COMPLETE SPECIFICATIONS ACCEPTED

18,522 (1922) and 3597 (1923). British Alizarine Co., Harley, Dawson, and Nichol. Discharging vat dyestuffs. (209,188.) Jan. 23.

28,691 (1922) and 16,458 (1923). Johnson (Badische Anilin u. Soda Fabr.). Treatment of cellulose esters for dyeing. (209,849.) Jan. 30.

32,911 (1922). Morton Sundour Fabrics, Ltd., and Thomas. Dyeing animal fibres. (209,569.) Jan. 23.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS

APPLICATIONS

Farbenfabr. vorm. F. Bayer u. Co. Manufacture of nitric acid. 1305. Jan. 16. (Ger., 26.2.23.)

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of bismuth compounds. 1709. Jan. 22. (Ger., 22.1.23.)

Haco Co. Bismuth compounds. 1294. Jan. 16. (Switz., 20.1.23.)

Harper and Williams. Production of ammonia. 1991. Jan. 24.

Imray (Meister, Lucius, u. Brüning). Manufacture of arsenic and antimony compounds. 1314. Jan. 16.

Kobelt. 1855. *See* XIX.

Mond (Metal and Thermit Corp.). Titanium oxide. 1851. Jan. 23.

Seth. 1189. *See* X.

Soc. Nat. d'Industrie Chimique en Belgique. Obtaining alkali sulphides. 1874. Jan. 23. (Fr., 23.1.23.)

Wefelscheid. Production of lead oxide. 1276. Jan. 16.

COMPLETE SPECIFICATIONS ACCEPTED

19,154 and 19,155 (1922). Weizmann and Blumenfeld. Titanium compounds. (209,480 and 209,441.) Jan. 30 and 23.

32,134 (1922). Nicholson. Neutralising ammonium sulphate. (209,561.) Jan. 23.

6596 (1923). Henkel et Cie., and Weber. Treatment of ammonium chloride lyes in iron vessels. (196,585.) Jan. 23.

14,929 (1923). Urfer. Manufacture of pulverised catalysts for the synthesis of ammonia. (199,025.) Jan. 30.

32,209 (1923). Weizmann and Blumenfeld. Titanium compounds. (210,033.) Jan. 30.

VIII.—GLASS; CERAMICS

APPLICATIONS

Comp. Générale de Basalte. Manufacture of basalt products. 1405. Jan. 17. (Fr., 23.2.23.)

Mond (Metal and Thermit Corp.). Refractory materials. 1850. Jan. 23.

Semple. Heat-insulating and fire-resisting materials. 1608. Jan. 21.

IX.—BUILDING MATERIALS

APPLICATIONS

Ioco Rubber and Waterproofing Co., James, and Nuttall. Manufacture of laminated materials for decorative etc. purposes. 1859. Jan. 23.

Mackay. Bituminous emulsions. 1885. Jan. 23.

Pearce, and Pearce and Co. Manufacture of a road compound. 2016. Jan. 25.

Petelot. Manufacture of cement. 1793. Jan. 22. (Fr., 31.1.23.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY

APPLICATIONS

Brearley, Johnson, and Ridge. Method of chromium plating. 1823. Jan. 23.

Conti. Alloys. 2067. Jan. 25. (Fr., 14.2.23.)

Lanz. Manufacture of grey cast iron. 1781. Jan. 22.

Montgomery. Recovery of zinc from galvaniser's flux. 1895. Jan. 23.

Seth. Obtaining vanadium compounds, or vanadium from pig iron. 1189. Jan. 15. (Sweden, 9.2.23.)

Soc. Electroquimica de Flix. Producing an electric arc for melting and projecting metals. 1407. Jan. 17. (Spain, 24.1.23.)

Talbot, and Talbot-Stead Tube Co. Steel alloys. 1974. Jan. 24.

Weissenstein. Manufacture of bearing metals. 1513. Jan. 18. (Austria, 23.1.23.)

Complete Specifications Accepted

27,934 (1922). Smidth & Co. Agglomeration of ore (187,601.) Jan. 30.

28,584 (1922). Soc. Anon. J. Cockerill. Tunnel furnaces for metallurgical uses. (195,590.) Jan. 23.

34,970 (1922). Constant and Bruzac. Production of steel and iron. (191,032.) Jan. 23.

4398 (1923). Aluminum Co. of America. Aluminium alloys. (195,048.) Jan. 30.

5141 (1923). Padmore, Padmore, and Padmore. Metallic alloys. (209,975.) Jan. 30.

14,578 (1923). Ashcroft. Treatment of lead-zinc sulphide ores, mattes, etc. (210,011.) Jan. 30.

15,667 (1923). Electro Metallurgical Co. Zirconium steel. (202,279.) Jan. 30.

19,052 (1923). Bailey. Case-hardening wrought iron or steel. (209,687.) Jan. 23.

XI.—ELECTRO-CHEMISTRY

Applications

Brearley and others. 1823. *See* X.

Hanson and Moe. Electric battery compound. 1024. Jan. 14.

Manhattan Electrical Supply Co. Dry cells. 1698. Jan. 21. (U.S., 30.7.23.)

Monnot. Electric storage batteries. 1293. Jan. 16.

Soc. Electroquimica de Flix. 1407. *See* X.

Wills. Electric accumulators etc. 1125. Jan. 15.

Complete Specification Accepted

7114 (1923). Schauly and Gernigon. Electric furnaces. (209,988.) Jan. 30.

XII.—FATS; OILS; WAXES

Application

Kumst. Apparatus for chemically combining water with oil, fat, etc. 1228. Jan. 16.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS

Applications

Dicker (Aars). Production of white lead. 1790-1. Jan. 22.

Farbenfabr. vorm. F. Bayer u. Co. Manufacture of lakes. 1306. Jan. 16. (Ger., 22.5.23.)

Ioco Rubber Co. and others. 1859. *See* IX.

Wefelscheid. 1276. *See* VII.

Complete Specifications Accepted

28,023 (1922). Schmidt. Waterproof coating compositions. (189,104.) Jan. 30.

28,243 (1922). Torrance. Mills for reducing paints, colours, and pigments. (209,829.) Jan. 30.

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

Argentina: Iron and steel (134); *Australia:* Hardware (118); *Austria:* Abrasives, grindstones, emery paper, carborundum (124); *Canada:* Steel (119); *Chile:* Photographic supplies (135); *Dominican Republic:* Pottery (8389/U.B./M.C./2); *Egypt:* Soap and palm oil (the Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W.1, M.U.H. 1924/27/8); *Germany:* Tin ingots and sheets, copper ingots (126); *Fiume:* Steel (125); *Italy:* Asbestos yarn (21787/F.U./M.C./2); *New Zealand:* Enamelled and aluminium ware (122); *Rumania:* Pharmaceutical products, chemicals (129); *Switzerland:* Steel (130).

French Company News

The Société Anonyme de Commentry Fourchambault et Decazeville is installing in connexion with its coke ovens at Decazeville a factory for the manufacture of synthetic ammonia, the necessary hydrogen being obtained from coke-oven gas. The Claude process will be utilised, tubes being used of a special metal made by the Imphy Steel Works. The plant will have a daily capacity of 5 tons, a figure which could be doubled eventually. It is intended to convert the ammonia produced into ammonium sulphate. The factory will probably begin work in the summer of 1924.

The Hagondange Works of the Union des Consommateurs de Produits Métallurgiques has recently lit its fifth blast furnace.

The Société Chimique des Usines du Rhone, which has been manufacturing cellulose acetate silk with the aid of the Comptoir des Textiles Artificiels, *has now perfected its process for colouring and dyeing these artificial silks.*

The Italian Artificial Silk Industry

It is announced that the Società Viscosa, of Turin, has decided to increase its capital from 350 to 600 million lire, to enable it to enlarge its factories. By the enlargements contemplated, the company, which is the largest manufacturer of artificial silk in Italy, will raise its output from 14,000 to 20,000 kg. per day. The increase is being financed by a consortium of Italian banks, and a share is being taken by a group of French artificial-silk manufacturers.

JOURNAL OF THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, FEBRUARY 15, 1924 No. 7

EDITORIAL

THE interesting contribution we have received from Professor G. T. Morgan requires some special mention. He is well acquainted not only with the theory and chemistry of dyes, but also with the progress which has been made in the production of them in this country. He has exact knowledge on many of those points where we and the general public must rely on popular rumour or that long experience which doth attain to something like prophetic strain. If we carry our recollections back a few years and consider our dyestuffs industry, taking a broad look and ignoring the details, we have sufficient to enable us to understand the present situation and its meaning. Before the war two or three important firms and a few smaller ones made dyestuffs; they had sufficient capital, sufficient chemistry and sufficient organisation to supply a small range of dyes to a few consumers. This was in some ways a considerable achievement, having regard to the complexity of the manufacture and to the excellence and power of the organisations manufacturing dyestuffs in Germany. The war came and we saw "a noble and puissant Nation rousing herself like a strong man after sleep and shaking her invincible locks." A great effort was made by the manufacturers of intermediates and of dyestuffs in this country. In spite of every difficulty an immense step forward was taken, and though we may now be critical of some of the decisions and policies, we cannot fail to pay a just tribute to the zeal, patriotism, energy and courage, which the manufacturers showed in this crisis. They built up an important and flourishing industry; nevertheless not an industry which in its present state can successfully compete on equal terms with the German industry, which, in science and in business, in organisation and in capital, is one of the most remarkable developments of modern times.

* * *

The largest, and in some ways therefore the most vulnerable, of the British manufacturers has recently sought some measure of safety. It is wise to agree with thine adversary while he is in the way with you, and the British Dyestuffs Corporation has apparently acted on this sage axiom. The German manufacturers have been equally willing and were they and the Dyestuffs Corporation the only people concerned it would be easy to do what has perhaps already been done and enter into contracts which will secure a profitable and useful future to both parties. The actual position here is complicated by the existence of some other manufacturers and some merchants not so powerful and well organised as to be able to put up a fight against the Dyestuffs Corporation and the German firms, but yet too important to ignore. It is not impossible, though it is difficult, to frame modifications which will enable them to continue their existence, but they would live rather on sufferance and we as a nation are not easily persuaded to enjoy a precarious prosperity so long as our foreign competitors think fit. Moreover, as we have many times pointed out in these columns, a dyestuff industry is essential to our fine chemical industry and a flourishing fine chemical industry is essential to our national prosperity. If it is admitted that these statements are true and if we also admit that our British dyestuff industry is not yet so firmly established and so well organised that it can stand up against our German competitors then it seems to us that the position is fairly plain. The alleged agreement with the German dye manufacturers would be, so far as the Dyestuffs Corporation is concerned, a solution of the problem, but it is not, either from its point of view, or from the national point of view, the ideal solution. It is a great change of mind, a great decline in spirit, for that puissant Nation recently "shaking her invincible locks."

Sometimes we wonder how the great men of past days would have viewed such a situation. There have been sensible and cautious statesmen and men of business who have been content with a line of small resistance; there have been others, much contriving, and much enduring, who, when important interests or national pride have been involved, have been "strong in will to strive, to seek, to find, and not to yield." There have been such men in our chemical industry; men endowed with that determination, which ultimately prevails over every difficulty.

* * *

The importance attached to the possession of trade secrets has, one must suppose, some good justification, since every large manufacturing concern and every one-man show believe that the nature and quality of their products owe much to "something" that their competitors do not possess. There is, without doubt, a "something" in the hands of an experienced manufacturer that is extremely difficult for the novice to acquire, but whether it is just knack, born of much practice, the special skill of an operator, a secret ingredient, or a real novel process

is not easy for an *outsider* to determine. One thing is very sure—a scientific *insider* puts no faith in trade secrets, though he may make much of them for a variety of reasons which redound to his local credit.

Many large manufacturing firms in the past, though it is to be hoped the practice is dying out, used to put a penalty clause in the contracts of their employees who were likely to become wise in the processes of the factory, and to demand a guarantee deposit, running into hundreds of pounds, as a security against the persons with newly-acquired knowledge passing over to competitors. Such a practice is altogether loathsome, and at once puts a price upon the individual's head, whilst it kills the natural inborn tendency of a decent man to play the game. Some of the old contracts are quaint to consider to-day, for quite often the penalty clause prohibited a man, dismissed from the concern or leaving of his own accord, from joining another firm making the same type of article, and, occasionally, handling the same raw materials. This was merely silly, and would have been recognised as such even by the "Hass," if the man found himself unable to support himself owing to a restriction of this nature.

The lot of a chemist in any manufacturing firm is seldom a happy one, and many of the more ignorant directors look upon him primarily as a luxury, sometimes as an unpleasant necessity, more often as a "nosey-parker," and invariably as an unreliable member of the firm from whom trade secrets should be kept. Herein lies the folly of the ignorant, for the chemist will be quick to find the hidden secret, and to realise more often than not that it was not worth the seeking.

Is there such a thing as a trade secret that can exist in the possession of one firm alone for any length of time? Is there any trade secret that cannot be learnt from without by sufficient application? Does the possession of a trade secret, or supposed secret, bring out the good in competition or increase the pride in the production of a good article?

Human nature is peculiarly astute, but it loves a secret both in the finding and in the telling. A secret will cause some men with the craving for knowledge many sleepless nights till it has been found, and will probably cost the lazier man, who prefers to buy it, a pretty penny when it is duly imparted. But the secret will be bound to circulate sooner or later, and each manufacturer, as he acquires it, will keep it jealously from his competitors, under the impression that he is, at the worst, one of a select few. It is certainly to be doubted whether any secret can withstand for ever a thoroughly scientific attack based on the number of permutations and combinations to be squeezed out of a variety of ingredients and processes.

Mass production does, almost invariably, kill trade secrets, and the spirit of "live and let live" will, let us hope, reduce the inflation of the importance too often attached through ignorance to the secret that is no secret. But if the possession of even an imagined secret gives added pride to the manufacturer in maintaining the quality of his product—"Let the play proceed."

THE MANUFACTURE OF POTASH AND OTHER SALTS FROM LEUCITE.*

By PROF. J. W. HINCHLEY, A.R.S.M., Wh.Sc., M.I.Chem.E., F.I.C.

It is a disquieting fact that the whole of the world's supply of potash is still obtained from practically one district (95 per cent. comes from Stassfurt, Germany, and 5 per cent. from Alsace). This is a matter of concern, not only to the British Government, but to the United States, Italian and other governments, and in these countries diligent outlook is kept with a view to obtaining equally cheap supplies from other sources.

The most hopeful source for supplies would appear to be the igneous rocks, which contain, on an average, 3 per cent., while some contain as much as 10 per cent. of potash. It is obvious that these igneous rocks may present some chemical difficulty in attack, as compared with the soluble salts of Stassfurt (sylvine, carnallite, etc.). In the case of these soluble salts of Stassfurt, a complicated and somewhat costly process of crystallisation has to be carried out to obtain pure products, but for agricultural purposes a crude product is usually satisfactory. If, however, pure minerals may be obtained from igneous rocks which are readily treated by chemical methods, it may be possible by these means to compete with the soluble salts of Stassfurt.

Of those minerals which occur in igneous rocks leucite is the most attractive. It is a comparatively rare mineral, except along the line of the Italian volcanoes.

It has some historical interest from the fact that Klaproth discovered potash in 1796, through examining it. The millstones of Rome have been made from leucitic lava for over 2000 years.

The use of leucite as a raw material for the manufacture of potash salts would bring another country into the potash market, and certainly relieve the world's situation with regard to potash, and possibly lead to the utilisation of similar or other minerals occurring in igneous rocks in other countries. Leucite ($K_2O,Al_2O_3,4SiO_2$) in a state of purity contains 21·5 per cent. of K_2O, 23·5 per cent. of Al_2O_3, and 55 per cent. of SiO_2. As a rule the natural mineral contains less potash, on account of the presence of magnesium and sodium, but this replacement of potash and other elements varies among the different volcanoes, and in some places, practically pure leucite occurs in extraordinarily large quantities.

Orthoclase is another mineral occurring in igneous rocks, which offers possibilities for the extraction of potash. It occurs in smaller proportion than leucite in the lavas of the Italian volcanoes, and, unfortunately, is usually associated with albite (soda felspar), so that whilst pure orthoclase contains 16·9 per cent. K_2O, 18·4 per cent. Al_2O_3, 64·7 per cent. SiO_2, that occurring in the Italian lavas contains only 7·1 per cent. of potash.

*Paper read at the joint meeting of the London Section, and the Chemical Engineering Group on Feb. 4, Dr. B. Dyer presiding.

In a few of the Italian lavas the amount of orthoclase exceeds that of the leucite; in a great majority it is much less, but in a large number of leucitic lavas, orthoclase is entirely absent.

Mr. Henry S. Washington has made a large number of analyses of the Italian leucitic lavas, and states that the average potash content is 8·72 per cent., whilst the average for all lavas, leucitic and non-leucitic, is 8·31 per cent. of potash. A region of igneous rocks so high in potash is unknown in any other part of the world.

The row of volcanoes extending 186 miles from Orvieto to Naples, contains seven craters, of which Vesuvius alone is active, the others being Bolsena, Vica, Bracciano, Alban Hills, Hernican Volcano, and Rocca Monfina. From a careful examination of the rocks during the war by Baron Blanc, it was found that the leucitic rocks of Rocca Monfina contain the

Fontanaradina, Rocca Monfina, Italy. Section of Leucitic Lava × 12

Fig. 1

purest leucite, the leucite being practically free from magnesium and sodium. The leucites of other volcanic regions contain in many cases considerable quantities of these elements.

The author has examined the leucitic rock obtained in the Rocca Monfina district, at places about half-a-mile apart, and has found that the composition of the leucite is practically the same.

The Rocca Monfina volcano lies about thirty miles to the north of Naples. Its igneous rocks cover an area of about 80 square miles, and are computed by Mr. Henry Washington to contain 1008 million metric tons of K_2O. There are some flows of non-leucitic lavas—basalts, andesite, and trachyte—but the leucitic lavas are the most abundant. The average content of potash in the latter is about 10·5 per cent.—the highest figure for K_2O in the whole of the Italian lavas. Occasionally on the surface the leucite is somewhat kaolinised, but this is the exception rather than the rule. At the centre of the volcano is a small cone, Monte Santa Croce, of non-leucitic andesite. It would appear that this volcanic district could supply the world with potash at the present rate of consumption for a thousand years.

The leucitic lavas which are being worked at the present time at Fontanaradina are about twelve miles from the little port of Scauri. The rock, after removing a very shallow layer of soil, is at once capable of being quarried, and by a simple telpherage system can be carried straight down over the intervening country to the wharf at Scauri by gravity. Fontanaradina lies about 370 metres above the intervening country, lying towards Scauri.

A photograph of a section of the rock is shown in Fig. 1; × 12. The regular trapezoidal form of the crystals is clearly shown. Examined under polarised light the crystals are found to be under stress; when heated to 500° C., however, this stress disappears and the simple crystalline form is revealed. Inclusions of gangue are very common in the leucites of many of the lavas, but this is not common in those of Rocca Monfina.

A view of one of the workings is shown in Fig. 2, from which the simplicity of the mining will be seen.

It will be obvious that unless the leucite can be separated from the gangue, the proposition of the manufacture of potash salts at a reasonable cost may be practically impossible. It has been found, however, that the small content of iron in the gangue is sufficient to permit of perfect electro-magnetic separation of the two materials.

The leucite occurs in the rock in crystals, varying from 3 in. in diameter to microscopic dimensions, but after crushing the rock and sifting to obtain uniform granular material, a very simple machine, which has been devised by Baron Blanc, brings about at a very rapid rate, the complete separation of the leucite crystals from the gangue.

The mill in which the crushing, sifting and electro-magnetic separation takes place, is shown in Figs. 3 and 4. The rock is crushed in jaw-breakers and rolls, sifted to separate into granular material and fine powder and then treated in "belt" electro-magnetic separators.

For chemical treatment it is desirable, for reasons which will appear later, to use material whose grains are about one-sixteenth of an inch in diameter.

The fine powder produced during the process of crushing may be used as a potash manure.

Dr. Voelcker has carried out a series of experiments during the last three years, on the value of powdered leucite as a manure, and has found as a general conclusion, from his experiments, that the value of leucite is practically identical with that of soluble manures of the same potash content. His pot experiments may be cited :—

TABLE VI

Treatment	Weight of corn g.	Weight of straw g.	Percentage of untreated Corn	Percentage of untreated Straw
1. Untreated	8·19	16·70 ..	100	100
2. Leucite—5 cwt. per acre	11·23	19·99 ..	137	119
3. Sulphate of potash containing potash equal to 5 cwt. per acre of leucite	11·00	18·55 ..	134	111

The chemical properties of leucite are extremely interesting, and there is little doubt that as it becomes better known it will be used for many purposes and in many processes in which it is at present unknown. The potash present is readily replaceable by many other elements. It is related to the zeolites, but contains no water. Its application to water softening and similar purposes is obvious.

The behaviour of natural silicates with acids varies enormously. In some cases the attack is nil, and in many cases in which attack takes place gelatinous silica is formed, and the separation of the liquids from the solids becomes extremely difficult, and may make the cost of treatment excessive and impossible. On treating powdered leucite with acids, solution takes place with evolution of heat and gelatinous silica is formed in sufficient quantity to make the process difficult on a commercial scale. If, however, granular leucite is treated with acids the amount of gelatinous silica formed is small, but still sufficient to seriously interfere with economic manufacture. Baron Blanc, however, found that if the acid liquid be continually circulated through the granular leucite a solution was obtained in which no gelatinous silica occurred. The gelatinous silica which must be formed through the presence of small quantities of powdered leucite is removed from the solution by the filtering or adsorbing action of the granular material. At the end of the process of solution in acid the crystals of leucite appear as little skeleton crystals of silica.

One of the Quarries

FIG. 2

The granular material obtained by the electro-magnetic separation of the crushed rock contains :—

K_2O	.. .. ..	18–20 per cent.
Al_2O_3	.. .. ..	22–24 ,,
SiO_2	.. .. ..	53 ,,

On examination of the crystals of leucite separated, there will be found inclusions of gangue, so that many of the grains consist partly of leucite and partly of gangue. On this account the separated material usually contains from 2 or 3 per cent. of gangue.

On treatment of the separated material with acid, a certain amount of iron enters into the solution, but the amount of iron is not sufficient to interfere with the chemical processes, or to affect seriously the purity of the chemical substances produced by very simple processes.

MANUFACTURE OF ALUM

Perhaps the simplest industrial process is that of the manufacture of alum and silicate of soda from this material. Potash and alumina are present in the correct proportions for forming alum by the action of sulphuric acid on the material according to the equation :—

$$K_2O,Al_2O_3, 4SiO_2+4H_2SO_4+20H_2O= K_2SO_4, Al_2(SO_4)_3, 24H_2O+4SiO_2$$

A plant treating 4 tons of leucite per day by this process is in operation at Pierre Benite, near Lyons, France. It yields 6 tons of alum per day.

Works seen from the Road

FIG. 3

Granular leucite is treated with circulating dilute sulphuric acid which is continually enriched as combination takes place. The heat of solution of the acid in the water and that due to the formation of alum raises the temperature of the liquor and the action becomes vigorous. By the circulation of the liquor through the granular mass, any colloidal silica produced at the beginning is absorbed by the silica formed, and a solution is obtained which is free from silica but contains a little iron.

It is well known that iron is a serious impurity in alum, and therefore it is essential that this iron should be completely removed from the final product. The gangue is almost unattacked by acid even when hot, so long as it has not been reduced to powder. In actual practice saturated mother liquors are used for the solution of leucite, and when the process is complete the temperature has been raised to about 95° C. On cooling, alum corresponding to the amount of leucite attacked, crystallises out, and is separated and washed in a centrifuge, by which a very pure alum is obtained. During this crystallising process the liquor should be agitated so that the crystals are produced in micro-crystalline form; as a result the whole of the iron remains in the mother liquor, and the crystals are obtained in the form known as fine crystals. About 20 per cent. of the alum present in the solution is crystallised out on each operation.

The mother liquors are used for a further treatment of the mineral, but as a rule the iron present is removed by simple chemical treatment, either in neutral solution by precipitation with a small amount of ammonia, so that a small precipitate of aluminium hydrate with ferric hydrate is formed; or, in acid solution, by adding a small amount of milk of lime or baryta to serve the same purpose. Agitation should be continued during this precipitation. On account of the large amount of water removed as water of crystallisation, the mother liquors, after being freed from iron, are diluted and again acidified and used for the treatment of a new batch.

The residual silica after washing with water, is removed from the dissolving apparatus, and on drying becomes reduced to an impalpable powder, and by a simple air separation gives a very pure product. This silica is remarkable in that it may serve at once for the formation of important silicon

compounds. As obtained in a dry state it usually contains about 18 per cent. of water, corresponding to $4SiO_2,3H_2O$. On drying in a vacuum desiccator at the ordinary temperature this is reduced to $4SiO_2,H_2O$; on being exposed to moist air, it again takes up water. Its properties correspond therefore with those of ordinary precipitated silica.

Manufacture of Silicate of Soda, etc.

On adding this silica to solutions of caustic soda or potash, even when very diluted, solutions of corresponding silicates are almost immediately obtained. The reaction takes place according to the equation :—

$$2NaOH + nSiO_2 = Na_2O,\ nSiO_2 + H_2O$$

Such silicates of soda and potash, when the air-separated silica has been employed, are extremely pure and may be obtained of practically any composition. Commercial silicates may be made by using the wet residue from the manufacture of alum. The gangue is not attacked by caustic soda or caustic potash, and is separated from the silicate solutions formed by settling.

The importance of this process of making silicates will appear when one compares it with the usual method of manufacture. It avoids the fusion of silica with the solid alkali and the subsequent treatment in an autoclave of the solid silicate obtained. The composition of commercial silicate of soda is (40° Bé) :—

SiO_2	.. .. ..	26·1 per cent.
NaOH	.. .. ..	9·8 ,,
Water	.. .. ..	54·1 ,,

The residual silica from Rocca Monfina leucite usually contains 5 per cent. of gangue and 40 per cent. of water. It is therefore a simple matter to calculate the amount of caustic soda solution of given composition to add in order that commercial silicate of soda (40° Bé) may be obtained.

The reaction is spontaneous and rapid; the caustic soda solution is placed in an ordinary vessel provided with an agitator, and the silica residue is gradually added. The reaction is exothermic, so that there is a rise in temperature. The operation may be accelerated in the beginning by warming the caustic soda solution. In practice, the silica is usually added slightly in excess, and while the liquor is hot it is rapidly pumped through a filter press, from which the silicate of soda of 40°Bé, issues, pure, colourless and transparent. The proportions used in practice amount to 474 kg. of silica and 549 kg. of soda of 29° Bé to obtain one ton of 40° Bé silicate of soda. The cost of production by this process in France with sulphuric acid at 22 centimes per kg. is 31 centimes per kg. for alum and 18 centimes per kg. for sodium silicate, or in round figures, with acid at £3 per ton, the cost of production of alum is £4 4s. per ton and of sodium silicate £2 19s. per ton.

The production of alum and silica of soda at Pierre Benite, corresponds to an 80 per cent. yield.

Hydrochloric Acid Treatment of Leucite

The treatment of leucite with hydrochloric acid presents greater chemical-engineering difficulties than the treatment with sulphuric acid, on account of the volatility of hydrochloric acid, and also of its greater corrosive action. The material is treated in a similar manner, as in the former case, but the plant must be completely closed, with a vent connected to a suitable scrubbing tower for the removal of hydrochloric acid fumes. This scrubbing tower may be packed with leucite with advantage, the water which trickles down it being used in due course to dilute the mother liquor obtained in the operation. Mother liquor in suitable quantity, (usually from 2 to 2½ cubic metres of liquor per ton of leucite treated), is continually circulated through a bed of granular leucite, and gradually acidified, as solution takes place. The circulation of the liquor is brought about by a centrifugal or other pump, and the liquor meets at one point in the plant hydrochloric acid gas, so that as attack takes place further acid is provided. For a reason which will be realised presently, strong acid solutions may reduce the rate of solution. In the course of 2 to 4 hours the whole of the potash and alumina has gone into solution and the temperature has risen to a little above 90° C. The amount of heat generated by the process is so great that the plant must be arranged to dissipate a proportion of it or the temperature may rise too high.

Since the solubility in the cold of aluminium chloride is much greater than that of potassium chloride (400% Al_2Cl_6 32% KCl); and since the solubility of potassium chloride is nearly twice as great at 90° C. as at 15° C., if suitable quantities are chosen, the whole of the potassium chloride dissolved in the reaction may be crystallised out, by cooling the resultant liquor obtained. In practice the amount of solution used is such that it is saturated with potassium chloride at a temperature not higher than 70° C. After discharge from the dissolver, the liquor is passed into a cooling apparatus, in which the potassium chloride crystallises out. Evaporating coolers are very convenient for this purpose, since the crystals form on the surface of the liquor, and the operation need only take a very few hours. About one third of the potassium chloride present in the liquor is crystallised out in cooling.

The magma of potassium chloride crystals and concentrated solution of aluminium chloride are run into a centrifuge, in the basket of which the potassium chloride is retained, and is washed with a small quantity of water, or potassium chloride solution, by which white crystals of 98/99% purity are obtained.

The aluminium chloride solution is now treated in a closed vessel with hydrochloric acid gas, when crystals of hydrated aluminium chloride are precipitated; the rise of temperature which takes place during this operation through absorption of hydrochloric acid is useful as it prevents any risk of further crystallisation of potassium chloride. At this point, water may be added to the liquor with advantage, to restore to the liquid some of that removed by the

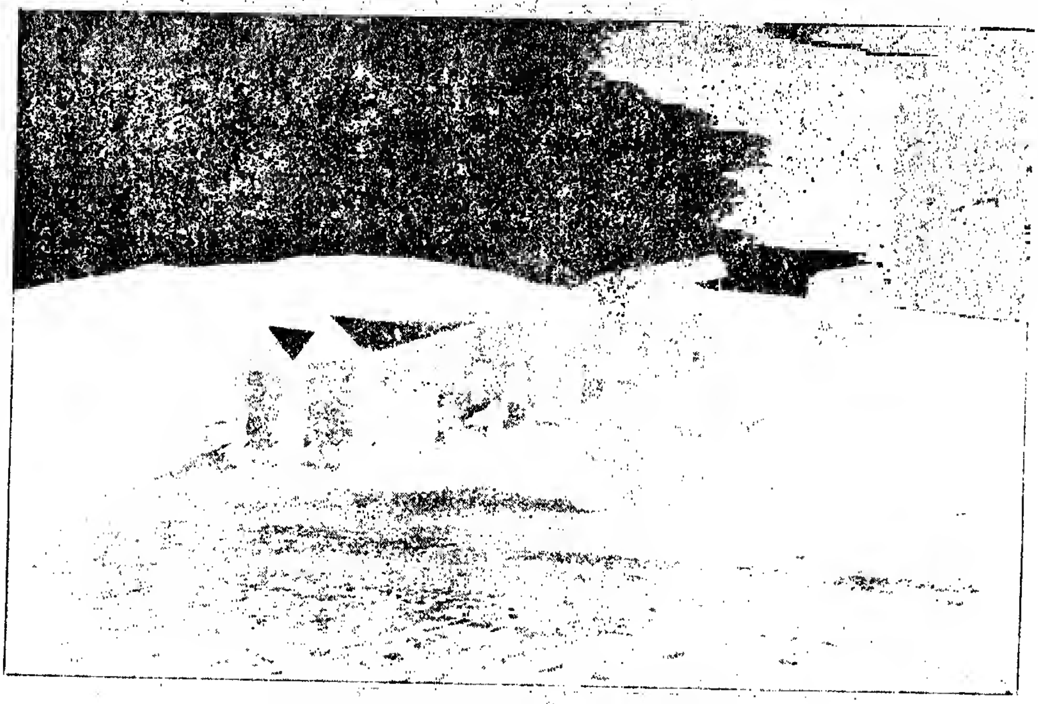
crystallisation of the aluminium chloride. The concentrated solution of hydrochloric acid and mother liquor thus obtained is transferred to the dissolver, whilst the precipitated hydrated aluminium chloride is transferred to a porous brick filter, washed with water, and drained.

By this method of operation, practically the whole of the potassium and aluminium present in the leucite is obtained in the form of potassium chloride and hydrated aluminium chloride. The process is one which needs careful attention to detail; it is obvious that the liquor at the end of the dissolving stage will be acid, and that there may be risk of precipitation of aluminium chloride on this account,

It will therefore be realised that this constitutes a simple cycle of operations, by which the same mother liquors are returned to the cycle continually, and any impurities may be concentrated in these mother liquors.

Ferric chloride accumulates this way, and tends to discolour the salts obtained, although simple washing easily removes it.

The author examined the results of a series of ten operations carried out on a small scale, and it appeared that the colour of the solution due to ferric chloride was practically the same in each case, a point being reached in the second or third operation by which the amount of iron eliminated with the



Works, with Rocca Monfina in the distance
Fig. 4

but practical experience has shown that some time is required after the end of the attack on the leucite, before the passage of the hydrochloric acid gas can give that degree of concentration which is necessary for the precipitation of hydrated aluminium chloride. The mother liquor rejected from the last operation will obviously be nearly saturated with potassium chloride, and it is obvious that if it is used for the attack on a fresh supply of leucite, the whole of the potassium in the mineral treated may be crystallised out by cooling the liquid. It is found that the volume of liquor needed for each operation is such as will contain about three times the amount of potassium chloride corresponding to that in the charge of mineral.

chlorides of potassium and aluminium, is equal to that entering the solution with each new attack. This state of impurity of the solution gives no cause for trouble. Although the iron may be readily removed in practice, it is found that there is no necessity for this, provided that the crystallisation of the two salts takes place while the liquid is in a state of agitation. The crystals which will form under these conditions are very pure and free from ferric chloride, except as wetted by the solution, and a small amount of washing water readily removes this.

The aluminium chloride obtained, may be further treated, so that hydrated oxide of aluminium is produced and hydrochloric acid driven off. This

process depends on the fact that hydrated chloride of aluminium when heated to about 280° C. decomposes according to the reaction:—

$$2AlCl_3,6H_2O = Al_2O_3,3H_2O + 6HCl + 6H_2O.$$

This reaction is carried out on a practical scale in a tubular furnace. The inclined rotary tube may be made of aluminium or of iron, since neither are attacked by hydrochloric acid at this temperature, even in the presence of water vapour. The hydrochloric acid thus produced serves for attacking a fresh charge of leucite, but it must be observed that it is associated with an equal amount of water; on the other hand also, for the purpose of ensuring that the aluminium hydrate is free from acid, an additional amount of steam may be introduced at the discharge end of the rotary tube. The alumina usually produced contains less water than the equation indicates—the amount corresponds to $Al_2O_3,1\frac{1}{2}H_2O$. The hydrochloric acid thus driven off, on being admitted to the dissolving plant, will play its part in the attack of the leucite, while the water vapour will pass off to the scrubbing tower connected with the plant.

Quantities of Materials

It is now worth while considering the relative quantities of materials required for carrying out this process:—618·3 kg. of hydrochloric acid gas is required to attack one ton of leucite (19 per cent. K_2O, 22 per cent. Al_2O_3), of which 471·1 kg. will form aluminium chloride, and 147·2 kg. will form potassium chloride. The 471·1 kg. fixed by the aluminium would, of course, be liberated if that aluminium chloride were transformed into aluminium hydrate. Should potassium sulphate be required, the displacement of chlorine from the potassium chloride by well-known methods, would mean that 197·6 kg. of sulphuric acid would be required per ton of leucite treated; the amount of liquor required is about 2500 kg. per ton of leucite. The reaction which takes place is the following:—

$$K_2O,Al_2O_3,4SiO_2 + 8HCl = 2KCl + 2AlCl_3 + 4SiO_2 + 4H_2O.$$

A small amount of water is thus produced by the reaction, but in a well-closed plant, the loss of water by evaporation during the process of solution, is sufficiently great to necessitate the addition of water. The water produced by the reaction is found to be associated with the silica, apparently in a loose state of combination.

Each molecule of aluminium chloride precipitated is associated with six molecules of water, as water of crystallisation ($AlCl_3,6H_2O$), so that in the treatment of one ton of leucite, 466 kilos. of water will be taken up in this way. The quantity of water required for washing the silica, is about 200 kilos. per ton of leucite treated, and is again used for washing the chloride of potassium and chloride of aluminium obtained.

Heat Equations

In the attack of leucite, we have three exothermic reactions which serve to bring and keep the liquid at the temperature of ebullition when one works with considerable charges of material. The reactions are as follows:—

(a) $K_2O + 2HCl = 2KCl + H_2O + 102{\cdot}3$ cals.
(b) $Al_2O_3 + 6HCl = 2AlCl_3 + 3H_2O + 67{\cdot}2$ cals.
(c) $HCl(gas) + nH_2O = 17{\cdot}3$ cals.

For one ton of leucite, it would appear, therefore, that by reaction (a) 227,253 calories are produced, and by reaction (b) 118,746 calories. With regard to the reaction (c), the total heat produced may be taken to be about 293,000 calories, for each ton of leucite treated. It will thus appear that 600,000 calories are generated by the attack of hydrochloric acid gas on one ton of leucite—a quantity of heat more than is required to bring and keep the liquid at the boiling point. It is therefore necessary to provide means in the plant of dissipating heat, and to conduct the reaction so that a temperature of over 90° C. is not obtained.

The decomposition of hydrated aluminium chloride in the tubular furnace is an endothermic one.

(d) $2AlCl_3,6H_2O + 211{\cdot}4\text{cals.} = Al_2O_3,3H_2O + 6HCl + 6H_2O$

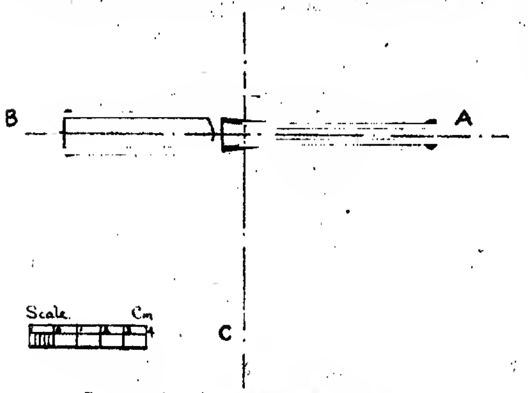
It will therefore be necessary to provide 2070 calories for each kilogramme of aluminium hydrate ($Al_2O_3,3H_2O$) obtained, which is equivalent to approximately 696,000 calories for each ton of leucite treated, assuming a production of 336 kg. of aluminium hydrate corresponding to 220 kg. of Al_2O_3. In addition, there is, however, the evaporation of the water associated with the HCl, which will absorb 10·8 calories per gramme molecule, so that about 149,000 additional calories are required for the vaporisation of the 233 kg. of water corresponding to the ton of leucite treated; thus a total of approximately 836,000 calories is required for the whole operation of converting the hydrated aluminium chloride obtained from the treatment of one ton of leucite into aluminium hydrate.

Taking factory operations, handling, say, 36 tons of leucite per day, about 5 tons of hydrochloric acid would be required, to which must be added any loss of hydrochloric acid which may be due to faulty chemical engineering. The cost of fuel for the treatment of this amount of material would be approximately 3s. per ton of leucite treated, and the products obtained would amount to $10\frac{1}{2}$ tons of potassium chloride, 8 tons of alumina, and 9 tons of silica. This estimate supposes a 93 per cent. yield.

I regret that I am unable to give views of the actual plant used to these processes, whilst the photographs in my possession of the small scale experimental plant in which the technical details were elaborated are too complicated to be of any value. The first factory experiments were performed in an ordinary stoneware tower, fitted with a plunger pump for the circulation of the liquid. The hydrochloric acid used was obtained by burning chlorine in hydrogen gas, produced from the electrolytic soda plant of the "Pomilio" factory at Naples. The commercial possibilities of this process depend mainly on the cost of the hydrochloric acid and the chemical engineering. In a factory where chlorine is a considerable by-product a careful consideration of costs will show the excellent commercial possibilities of this method of treatment of leucite.

The chemical-engineering problem of designing plant for the manufacture of alum and silicate c

soda presents no difficulty, since the ordinary materials of construction used in handling such products can be adopted, and apart from the provision of a circulating pump the plant may be designed in very many forms without serious effect on its efficiency. In the case, however, of hydrochloric acid treatment, on account of the volatility of the gas and the limited number of constructional materials available, the problem is far more difficult. If stoneware is used, the rise in temperature which occurs during the process may bring about stresses and failure through the serious cost in renewals and repairs. The removal of the silica obtained increases the difficulty of the problem if the usual methods are employed. Since the dissolving operation does not involve a temperature higher than that of boiling water, materials containing rubber may be used, and recently a new material containing a small amount of rubber has been produced, which seems to have all the qualities required for the construction of apparatus for this purpose. There is little doubt that soft rubber suitably prepared and supported by wood framing may also be used with success. In the plants erected on the Continent, stoneware, ebonite and soft rubber are used, but it would appear that



Silica Ejector. Sectional Elevation

FIG. 5

soft rubber or a composition of rubber might be used entirely, provided that the problem of dissipation of heat is properly attended to. Silica, cerotherm and similar materials might be used for those parts of the apparatus where heat dissipation occurs, and by the use of rubber connections stresses could be avoided.

The removal of the silica formed can be readily accomplished by means of ejectors. This method avoids doors, joints and stresses, and at the same time the operation is more rapidly and more efficiently conducted. Compressed air or steam may be used as the motive fluid, but as a rule steam should be preferred. The material of which they should be made must be hard and acid-resisting. For general purposes there is nothing better than a silica ejector, the body being protected by a rubber casing. Fig. 5 is a drawing of a useful type. Soft rubber tubing is carried from leg C, to the vessel to be emptied, steam is admitted by a flexible hose by leg A, and a rubber hose for delivery is connected to leg B. The granular mass associated with washing water in the dissolver is blown by the ejector on to a porous brick filter bed or draining bin, from which it may be taken for drying, air separation, etc.

These processes are due to Baron Blanc. Several other processes have been worked out, but have not been extensively used. The process of Dr. Hæge for making a phospho-potassic fertiliser has been worked to some extent. An acid process using nitric acid, an electric furnace process for the production of potassium carbonate and alumina, and a method of producing caustic potash call for some remark. The two last are due to Felix Jourdain. For producing caustic potash, powdered leucite and slaked lime with water are placed in an autoclave and treated for 3 hours at a pressure of 200 lb. per sq. in. The volume of the mass increases three times, and after two operations a solution containing 12 per cent. KOH is obtained. In a typical run with a 5-litre autoclave, 500 g. of powdered leucite, 400 g. of hydrated lime and 3 litres of water produced 51·6 g. of KOH, a yield of 95 per cent. Chemical engineering difficulties of handling the material, separating and concentrating the solution, are present, but the process is attractive. The residue in the autoclave is an excellent cement.

Discussion

Dr. J. A. Voelcker said that, as Professor Hinchley had very rightly observed, the need for potash in the agricultural world is undoubted. At the time of the war we had found ourselves dependent upon Germany for potash, and a potash famine was staring us in the face. We managed to get through that time, but it was not long before we felt that we must look elsewhere for supplies. Just then this new material, leucite, came along, and agricultural chemists turned to it very hopefully as another source of potash. When it was first brought to this country he was disposed to treat it, as he had treated several other sources of potash that had been proposed, such as the granites, felspars, and other insoluble materials of that kind, with some doubt; but leucite showed itself to be soluble to a large extent in hydrochloric acid, and even to give up a fair amount of its potash with such a weak acid as citric acid. Experiments that he himself had carried out with it had given most favourable results and there really was no reason why, being so readily comparatively soluble, it should not become an ordinary source of potash. In fact, it differed very little in effect from sulphate of potash containing an equivalent amount of potash. He believed that he was correct in saying that the reason we did not know of the existence of potash near Rome was due to the Germans, who not only knew something about these leucite deposits, and kept it up their sleeves, but had succeeded in persuading the Italians that these deposits were no good. Happily, this new source had now been opened, and he was disposed to believe that it was a very hopeful source of potash supply. Though he was not given to being over sanguine, he had

no hesitation in saying that he was very hopeful indeed of this source of potash if only it could be produced at a reasonable price; subject to that, he regarded the leucite deposits as likely to be a very valuable contribution to our sources of potash supply.

Dr. W. R. Ormandy said that the importance of these new deposits, of course, could not be denied, but the question was how far we as a nation were going to benefit from them. He did not feel, at the moment, that the leucite deposits of Italy would be of much benefit to us unless we had some hand in their control, and that was essential if we were to spend large capital sums in connexion with this new material. It had been pointed out that the first and simplest method of treating this leucite was to convert it into alum; but the world's market for alum was a comparatively small one, and this aspect might be ruled out as being of any very serious importance. Prof. Hinchley said the alum was approximately 99 per cent. pure, but commercial alum to-day might contain only 0·01 or 0·02 per cent. of iron, and for many fine chemical industries the permissible content of iron in alum was of the order of 0·001 or 0·002 per cent., so that more specific information was required before it could be said that the leucite product was of commercial quality. The value of this product could not be based on treatment with sulphuric acid, since the market for alum is so infinitesimally small in comparison with the potash requirements of the world. Therefore, the production of alum as the first process might be ruled out as being a serious outlet for a supply of potash which was said to run into thousands of millions of tons. Consequently, we were dependent upon the hydrochloric acid method, and here, as Professor Hinchley had said, the problem of handling hydrochloric acid in hot solution needed solving. Hitherto, on the Continent, they had used stoneware plant, which was immensely expensive, sensitive to changes of temperature, and easily damaged. Professor Hinchley had found a rubber for chemical plants dealing with hydrochloric acid at 100° C., which, under these conditions, would last for a long time; Professor Hinchley had been much more fortunate than he himself had been, or hoped to be. The problem of finding a material to deal with hydrochloric acid had, he believed, been solved in Switzerland. He had just visited a plant there which had been in use experimentally for two years, and in which hydrochloric acid, both as gas and liquid, was being boiled at 100° C. in vessels 9 ft. in diameter and 20 ft. high, made monolithic, and there was not the slightest evidence of any action. The manufacture of this material depended upon a concrete using pitch instead of Portland cement as a binder. Ordinary gas works pitch was a fluid, but it was possible to make hard pitch from it by mixing 7 per cent. of molten pitch with fine silica, then adding coarser silica, and then adding ¼-in. silica. This substance could be cast into various forms, but they lost their shape and deformed at a temperature of about 30° C. It has now proved possible, however, to make pitches which have the peculiar property that at a temperature of 100°, if mixed with siliceous material and cast into a bar, they will not change their shape unless sufficient pressure is applied to make them break suddenly. By means of such pitches a pitch concrete had been made which can be poured and cast into pipes having a thickness of wall of 9 mm. and a length of 6 ft., or it can be made into vessels 10 ft. in diameter and 20 ft. high, which will stand hydrochloric gas or fluid up to 100°. The cost of plant made with this material is about 20 per cent. of that of stoneware plant to carry out the same work, and therefore it appeared that the problem of finding a material for dealing with hydrochloric acid at high temperatures was capable of solution. How far could the development of the Italian leucite deposits be of value to this country? They were valuable in that they are an alternative supply, which is not controlled by Germany or by France, but he still failed to see how it was going to pay English industry to spend large capital sums for the commercial development of a material the control of which, like the control of potash, was as much out of our hands as the Alsace-Lorraine and Stassfurt product was. It was eminently desirable that we should have a supply, and an essential method of dealing with the difficulty might be to form an international company in Germany, in which we should have a share, so that we did not spend our capital to develop this product only to find later that an area 40 miles away was being developed and the leucite sold at a lower price to our competitors.

Mr. Howard Spence said that Baron Blanc had rendered enormous service to chemical industry by the processes that he had developed. The actual use of leucite had been known and practised 15, 20 or 25 years ago, one process being operated for quite a considerable time. Others, too, had experimented with it on a large scale, but they failed because they were unable to produce leucite at anything like a commercial price. Apparently these early workers were operating on some material which was not of the character of that being worked by Baron Blanc, *i.e.*, leucites which had largely decomposed under atmospheric conditions, and which, with a certain measure of difficulty, allowed the separation of the leucite crystals from the gangue by hand labour without any mechanical operation at all. Baron Blanc had developed a most interesting and ingenious process, apparently by going to the true source of the raw material, where it occurred in unlimited quantity, and being able to separate it under controlled conditions at a very low cost. The other processes worked out by Baron Blanc were also extremely interesting, and their development would be watched with great interest by the chemical industry.

Dr. R. Lessing said it so happened that leucite constituted the subject-matter of what he believed was his first consulting job twenty years ago. At that time some interest was taken in the exploitation of leucite, which came very largely from further north, nearer Rome, and the Italians at the time tried to induce English industrialists to take a hand in the matter. The process then being tried was an

alkaline one, and alumina was to be recovered from the solution by treatment with carbonic acid. The process came to nothing because the chemical and engineering difficulties were under-estimated, and nobody like Baron Blanc was found to carry on the work. A process which was worked out in America, although not, he believed, on a very large scale, consisted in treatment with ammonium chloride. It was a high temperature process, and the ammonia could be recovered.

Dr. R. Seligman said he had come to hear something about the production of alumina from these ores. Did Prof. Hinchley say that the decomposition of the aluminium chloride was carried on at about 350°?

Prof. Hinchley said that it began at about 280°, but the actual temperature of the tube in the furnace was about 300° to 350°. At that temperature they got a white product free from aluminium chloride, but it contained traces of acid in the first treatment.

Dr. Seligman said he would next like to ask as to the purity of the product. Prof. Hinchley had said the alum was nearly pure, which did not go far enough.

Prof. Hinchley said it could be absolutely pure; with only 0·001 per cent. of iron, and free from silica.

Dr. Seligman then asked as to the physical and other properties of the alumina, which, he said, were as important as the purity. The alumina used for the production of aluminium to-day was very largely made by the so-called Baeyer process, in which sodium aluminate is decomposed with the production of hydrate. The calcination of the hydrate was one of the most serious problems of the manufacturer, because not only were there considerable losses when the calcination was carried out, but it was very difficult to render the alumina produced non-hygroscopic. If it took up water, as it very easily did, the losses when it was subsequently put into the aluminium reduction furnace were very serious. It had always been his hope that by some such means as those described by the author, it would become possible to obtain alumina which is much more readily rendered non-hygroscopic. He was very anxious to know whether that was so, because in calcining by the Baeyer process it was necessary, either to work at a very high temperature, which was costly, or to use catalysts to get the change from the hygroscopic to the non-hygroscopic state. Alumina so treated caused difficulties in the reduction furnace. The change did not occur anywhere near 800° C. There was no difficulty in getting rid of the water, but it was the subsequent change which was of interest.

Prof. Hinchley said it occurred in this case between 600° and 800°, and the material was always non-hygroscopic. It was one of the questions that was being pursued, but the various processes had not yet been fully worked out for the commercial purposes to which the materials were being applied. The alumina was obtained in the ordinary way with 1½ molecules of water, but at 600° it seemed to be absolutely free from water, and there seemed to be a change.

Mr. Norman Swinden said he had been engaged for three years on investigating materials to withstand hydrochloric acids. He had found a rubber base to satisfy all the requirements of a plant to carry out all the operations mentioned that evening up to 110°. He had not found ebonite and pure rubbers satisfactory. He wanted a material which would resist the action of hydrochloric acid up to 110° C., which would neither contract nor expand on heating and which would not cost more than 1s. 6d. per lb., and which also could be taken to the far regions of the earth and be used by natives under skilled European control. At the moment a large plant, made entirely of rubber, including the boiler, was being put up in London for the treatment of hydrochloric acid and saturated brine. What was in mind was a material like sand which could be cemented together by the smallest possible quantity of rubber. The sample pot which he exhibited was lined with a leaded rubber compound, and all the processes were being carried out with that material. If this material was heated to 95° or 100°, it underwent surface change, was hardened and became more or less impervious. The rubber people said it was not vulcanisation but it was good enough for the purpose for which it was required. Furthermore, it had the advantage that alterations could easily be made, because one only had to cut a hole with a knife and weld a piece of rubber in. The material was delivered in the rough state and the rest was done by unskilled labour. Cocks, valves, tees, etc., were made in this way. The material would transmit 200 calories per sq. mm., per hour, and it formed a basis for the designing of plant for the dissipation of heat. Another great advantage of this material was that if softened it became doughy and could be used without any trouble for lining peculiar shaped vessels used in chemical engineering and covering agitators, paddles, etc. It was easy to cover such things with this material or line them without any trouble.

Prof. J. W. Hinchley, replying to the discussion, said that the successful commercial treatment of Italian leucite might bring about the treatment of other materials which we might have in this country although at present there might be no suspicion of their existence. He did not believe that the mineral riches of the British Isles were thoroughly exhausted. It might still be possible to find a source of potash in this country of which the development of leucite in Italy might be the first stage. The purity of the products depended entirely on the men in charge of the operations. It was possible to get very pure products and also extremely impure products. On the other hand, the purest materials demanded by the trade can be readily obtained, and he had been informed by Mincing Lane merchants that the products which had been put forward, *e.g.*, alum, were purer than the ordinary products usually sent there. He should not think of using a silicate of soda cement for hydrochloric acid plant but he was surprised to find it was successfully used when special precautions were taken. The Rocca Monfina deposits of leucite were in the hands of one firm and an analysis of the leucite from seven other volcanic areas showed that these materials had nothing like the purity of the Rocca Monfina. Alumina can be

produced to a degree of purity, with greater ease and at a lower cost by this process than by any other. The cost of precipitation and filtration alone represented a saving of half. Prof. Hinchley said he was pleased that Mr. Norman Swinden had spoken because although in the course of his paper he had mentioned the pot made of material with a rubber base, he did not like to say that Mr. Swinden had handed it to him several months ago in order to test it. He had, however, had it under test with hydrochloric acid, although he had not had the acid boiling, but the material had stood up well to the temperatures that had been used; the test was not completed yet. Mr. Swinden considered the material satisfactory and from the scale upon which he was using it, and from his (Prof. Hinchley's) own experiments, he believed Mr. Swinden was correct. A heat transmission rate of 200 calories per sq. m. per hour at first sight appeared low, but that rate was perfectly satisfactory for nearly all chemical plant. The size of the plant, of course, was affected by the rate of the heat transmission, but it was always possible to use other materials in conjunction with this one when a greater rate was required. Research on this aspect was still going on.

THE BRITISH AND GERMAN DYESTUFFS INDUSTRIES

By Prof. GILBERT T. MORGAN, O.B.E., D.Sc., F.R.S.

The Editorial of *Chemistry and Industry* for February 1 refers to negotiations which have recently taken place between the British Dyestuffs Corporation (B.D.C.) and the German chemical combination known as the Interessen Gemeinschaft (I.G.) and the subject has been widely ventilated in the daily press during the last three weeks, although so far no authorised version of the alleged agreement has been made public. Nevertheless, current rumours have already given rise to an extraordinary divergence of opinion as to the outcome of this new development. On one hand it is stated that the first overtures came from the magnates of the I.G., who had become genuinely alarmed at the rapid success of the British dye industry. Meetings began in 1921 and conferences have been held since in several continental capitals with the result that the Directors of the B.D.C. having made clear their position of independence in respect of supplies of German dyes, have returned from Berlin bringing "peace with honour" together with an agreement which will increase the efficiency of the dyemaking industry in this country.

Less optimistic views are, howe[illegible] by other interested parties. One section [illegible]ye users is becoming alarmed at the prospe[illegible] an Anglo-German monopoly controlling the supplies of essential colouring matters. The dyemakers outside the state-aided merger, who are also among the critics of the proposed arrangement, have not yet published any official opinion but it is obvious that their interests are gravely involved.

Whatever may be the fate of the agreement it is interesting in view of the *rapprochement* between the leading British and German colour firms to read again reports of speeches made in 1915 and since in connexion with the establishment and the subsequent developments of British Dyestuffs Ltd. and its present successor. One of the Government directors of the B.D.C., who is stated to have been present at the Berlin conference, was formerly Sir Albert Stanley, who in 1918, as President of the Board of Trade, referred to "the dye industry for this country free for all time from any association with Germany."

Certain terms of the agreement were disclosed by the *Manchester Guardian* on January 25, and although repudiated by the B.D.C. as "unauthorised and premature," they were subsequently confirmed by Dr. Duisberg of the I.G.

They may be summarised as follows:—

(1) A monopoly of the British market for the B.D.C. with a percentage share of foreign and Colonial markets; (2) the B.D.C. shall be able to draw on the I.G. for *personnel* and for information as to manufacturing and technical processes; (3) the I.G. to receive half the profits of the B.D.C.; (4) the B.D.C. to offer such dyes as it imports at world prices; (5) reparation deliveries of dyes to cease.

It is probably the second clause which will arouse the most acute feelings in the minds of chemical readers. The policy implied is by no means new; several of our pre-war colour makers had recourse to a *personnel* drawn from foreign sources. "A German chemist with a process" was the favoured recipe, but the dye shortage of 1914 was the sequel to this easy-going dependence on alien aid.

Before the reintroduction of German chemists changes completely the essentially national character of our dye-making undertakings it seems desirable to direct public attention again to the meritorious advances in the manufacture of dyes and intermediates which have been accomplished in our dye factories during the past five years (*v.* The New Dyestuffs Industry of Great Britain, *Chemistry and Industry*, September 14, 1923).

These remarkable achievements were a revelation to those members of the Dyestuffs Development Committee of the Board of Trade who recently visited some twelve of the representative colour works of Great Britain. Two lines of improvement were apparent: the range and purity of dyes and intermediates were being increased, while the cost of production was being diminished rapidly as the result of further experience in the manufacture of these highly complicated chemical materials on a large scale.

In view of this striking demonstration of manufacturing aptitude on the part of British chemists the following extract from an article on "A Dye Combine," published by the *Manchester Guardian* on January 25, must be regarded as misleading and very unfair to our colour chemists:—

"Under its [the Dyestuffs Act] shelter we have tried with conspicuous ill success to foster an industry which shows no signs of being able to stand on its own legs when the protection is withdrawn." It is only right to add that in reply to a spirited protest a partial qualification of this assertion was made a

few days later as regards "the efforts of the independent dye makers." The truth of the matter is that no distinction can be drawn between the chemists employed by "independent dye makers" and those on the staff of the B.D.C. Both sections of British chemists have made good in such a way as to astonish their best informed critics, the chemically trained chiefs of the I.G. This success of the British chemist furnishes at the same time a reason for the German overtures and the only possible justification for the accommodating attitude taken up by the Board of the B.D.C. But although in certain contingencies, working arrangements with foreign manufacturers may be desirable, as for instance the one by which the Clayton Aniline Co., although under Swiss inspiration, continues to employ English chemists and operatives and to extend its plant for the manufacture of dyes and intermediates in this country; yet it is very doubtful whether, on the lines of the proposed agreement, the non-technical directorate of the B.D.C. will be able to maintain a position of independence in association with such past masters of colour chemistry as the chemical directors of the I.G.

If this foreboding is justified the outlook for the British synthetic colour industry is deplorable. For it should never be forgotten that the vital importance of this branch of applied chemistry lies not in its financial value but in its educational aspect. It is the only chemical trade which can offer on an extensive scale a training in industrial synthetic chemistry, the ramifications of which spread throughout the high grade industries subserving the needs of modern civilisation.

The great factories of the I.G. are industrial universities within which German chemists continue their vocational studies, thereby diverting their technical knowledge into profitable channels. Before the war her indigenous industry in coal tar products had endowed Germany with the chemical hegemony of the civilised world. It remains to be seen whether the proposed agreement will retain for British colour chemistry "a place in the sun."

The announcements in the press of this compact were accompanied in many instances by a flash of grim though probably unconscious humour. The German combine was repeatedly described as the Inter-Essen Gemeinschaft, a timely reminder that German dye making is not entirely dissociated from the war-time activities of Messrs. Krupp.

PULVERISED "COALITE"

In considering the question of the use of pulverised fuel and the complete solution, as represented by the "Lopulco" patents, of the various problems, such as the wear and tear on the brickwork, the cost of drying and pulverising, the slagging of the ash, and the depreciation of the plant, it is interesting to note that pulverised "Coalite" can be burnt by the Lopulco system with equally remarkable results, namely 85–89 per cent. boiler plant efficiency, in addition to being superior to mechanical stoking in many other directions. If the fuel is pulverised so that 90 per cent. will pass through a 100-mesh screen (100 holes to the linear inch) and 65 per cent. through a 200-mesh screen, the contact with the air for combustion is so intimate that only 20 per cent. excess over the theoretical amount is required, and almost any carbonaceous fuel can be burnt at the highest efficiency, irrespective of the ash and the volatile matter. Thus, in the Ford plant at Dearborn, Detroit, blast furnace gas, pulverised coal, coke-oven gas, pulverised coke, and oil are used with equal facility, although the normal fuel is 70 per cent. blast furnace gas and 30 per cent. pulverised coal.

"Coalite," which contains 8 per cent. of volatile matter, would of course be a particularly easy fuel to burn in a pulverised condition at the highest efficiency, especially because the modern hollow air-cooled brickwork combined with a very large furnace volume allows the most intense heat and the maximum radiant efficiency to be maintained continuously for months without difficulty. It will be remembered that "Coalite" is particularly efficient in this respect, and for ordinary solid fuels in the open household fire, the radiant efficiency is approximately per cent. "Coalite," 35; coke, 30; semi-bituminous coal, 30. The great development in pulverised fuel-burning seems to be in fact only another argument for the wholesale low-temperature carbonisation of our coal, and the rapid extension of the "Coalite" process is coming at a very opportune time.

MIDLAND JUNIOR GAS ASSOCIATION

At the meeting on February 9, Mr. W. A. Twine, A.I.C., M.I.M.E. (supt. of Chemical Plant, Birmingham Gas Dept.), gave an address on "Chemical Engineering in Gas Works Practice."

In the course of the address he said he was confident that in the future only those who were prepared to make a study of chemical engineering alongside their other training would be qualified as first-class gas engineers. This fact had been overlooked by those who had been framing the syllabus for training the gas engineer. Many patents connected with the chemistry and physics of gas manufacture were unsuccessful in practice largely because the scientist was not an engineer, or the engineer was not a scientist. The friendliest feeling existed between the chemical and gas industries though from time to time the relations became strained. This was largely owing to the short-sighted policy of the chemical manufacturers that gas undertakings were driven more and more into chemical manufacture owing to the high prices they were charged on occasion for chemicals they required, or the low price offered for gas residuals. The speaker then discussed various improvements in gas-works practice, such as the use of waste heat from the retort house to distill the gas liquor, the removal of sulphuretted hydrogen by improved methods, and means of reducing losses of ammonia.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on February 8, 1924, Mr. E. V. Evans, and (subsequently) Sir Wm. J. Pope, F.R.S., in the chair. The President was unfortunately absent on account of illness.

The Council at its previous meeting decided to award the Messel Medal for 1924 to the Rt. Hon. Viscount Leverhulme, and the following cable had been received from him in reply :—

"Profound thanks distinguished honour Society Chemical Industry conferred and accept relying members will generously accept unworthy but sincerest efforts prove myself entitled their confidence.—Leverhulme."

Intimation was made of the death on January 24 of Mr. A. C. Flint, assistant secretary of the Chemical Engineering Group, and of the Institution of Chemical Engineers. It was agreed to send a letter of sympathy to his widow.

It was decided to give a donation of £100 to the Library Fund of the Chemical Society for the year 1924.

The financial arrangements that had been made for carrying on the work of the Bureau of Chemical Abstracts were reported to the Council and were approved.

Reports of various committees of the Council were submitted; and twenty-one new members were elected: Home 15, Overseas 6.

Dr. Geoffrey Martin and Dr. David Prentice were nominated as delegates from the Society to the International Cement Congress which is to be held, under the auspices of the Institution of Structural Engineers, at the International Building Exhibition, Olympia, London, on April 22 and 23.

A preliminary announcement as to conditions and privileges of membership of the World Power Conference was laid on the table.

It was reported that Mr. W. J. Leonard, a member of the Society, had by a codicil, dated August 19, 1921, to his will, directed his trustees to pay to the Society the sum of £5000 as soon as a definite scheme for the provision either by the Society or in conjunction with other chemical societies of a building and accommodation to form a Centra Institute and Club for Chemists has been decided upon and is being carried into effect, the decision of the trustees as to whether such scheme has been decided on and is being carried into effect or not to be final and binding upon the Society. In the meantime, the income from the Trust Fund will be paid yearly to the treasurer of the Society for the general purposes of the Society for a period of seven years from the time of the testator's death or until before the expiration of such period a definite scheme has been decided upon. But if at the expiration of such period of seven years no definite scheme as aforesaid is being carried into effect then the Trust Fund shall fall into and form part of the testator's residuary estate. It was resolved: (1) To express the thanks of the Council to Mr. Leonard's trustees, and (2) to open a fund, to be called the Leonard Bequest Fund, into which all moneys shall be paid, including the income from the Trust Fund. It was further decided that at next meeting of Council a scheme for carrying out the objects of the fund should be submitted for discussion.

The next meeting will be held on Friday, March 14, 1924, at 2.30 p.m.

FORTHCOMING EVENTS

Feb. 15. SOCIETY OF CHEMICAL INDUSTRY, *South Wales Section*, in the Technical College, Swansea, at 7.15. "The Increased Application of Physical Metallurgy for purposes of Control." By H. J. Williams, F.I.C., and L. Tavernor, A.R.S.M., D.I.C.

Feb. 16. SOCIETY OF CHEMICAL INDUSTRY AND INSTITUTE OF CHEMISTRY, *Bristol and South-Western Counties Sections*. Annual Dinner, to be held at the Royal Hotel, College Green, Bristol, at 7 p.m.

Feb. 18. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, W.C. 2, at 7 p.m. "Electrical Development in France." Discussion to be opened by E. M. Malek.

Feb. 18. INSTITUTION OF CHEMICAL ENGINEERS, The Engineers' Club, Coventry Street, W., at 8 p.m. "The Transport, Storage and Distribution of Hydrochloric Acid, with an Account of a Complete Modern Installation," by D. M. Newitt, B.Sc.

Feb. 19. HULL CHEMICAL AND ENGINEERING SOCIETY, Hull Photographic Society's Rooms, Grey Street, Park Street, Hull, at 7.45 p.m. "The Manufacture and Testing of Portland Cement," by Miss D. J. Butterfield.

Feb. 20. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section*, University College, Nottingham, at 7.30 p.m. "A Note on the Estimation of Poisonous Metals in Gelatin for the U.S.A. Food Laws," by S. R. Trotman, M.A.. "The Weathering of Cotton and Wool, with Special Reference to the Action of Bacteria," by R. W. Sutton, B.Sc.

Feb. 20. SOCIETY OF GLASS TECHNOLOGY, Sheffield. "Recent Advances in Pyrometry with Practical Demonstrations."

Feb. 20. ROYAL SOCIETY OF ARTS, W.C. 2, at 8 p.m. "New Uses for Rubber," by P. P. Burgess.

Feb. 21. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "The Rotatory Dispersive Power of Organic Compounds. Part XI. Octyl Alcohol and Octyl Oxalate." By T. M. Lowry and E. M. Richards. (2) "Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXII. Simple and Complex Rotatory Dispersion." By H. Hunter. (3) "The Rotatory Dispersive Power of Organic Compounds. Part XII. Borneol, Camphor, and Camphorquinone. Asymmetric Atoms and Asymmetric Molecules." By T. M. Lowry and J. O. Cutter. (4) "The Rotatory Dispersive Power of Organic Compounds. Part XIII. Halogen-derivatives of Camphor. Optical Superposition in the Camphor Series." By T. M. Lowry and J. O. Cutter.

BIRMINGHAM AND MIDLAND SECTION

Dr. E. B. Maxted presided over the meeting held on February 5, when Mr. E. J. Lush, of the Technical Research Works, London, read a paper on "Some Studies in the Kinetics of Oil Hydrogenation." Briefly describing a continuous process of hydrogenation, he showed by means of graphs that temperature played an important part in the formation of *iso*-oleic acid, but that the pressure of the hydrogen was without apparent effect on composition. The continuous process was, therefore, deemed suitable for measurements on the rate of hydrogenation with change of pressure. Charts were shown giving the experimental results for the effect of pressure on the rate of hydrogenation of cottonseed, palm kernel, coconut and groundnut oil. Except for coconut oil, the rate of hydrogenation was found to be approximately proportional to the square root of the pressure. This was further confirmed by maintaining a constant degree of hydrogenation (as measured by the iodine value of the oil) by a simultaneous change of rate of flow of oil and pressure, so that the two effects balance one another. A suggestion as to the cause of the difference in the effect of pressure in this and other processes was put forward for discussion.

MONTREAL SECTION

During the 1923-24 session most successful gatherings have been held since the inaugural meeting on October last. The Executive Committee of the Section had decided to secure greater publicity, and the co-operation of the Press in bringing the importance of chemical industrial problems before the public. With this point in view, the chairman of the Programme Committee, Dr. A. R. MacLean, has been eminently successful in securing prominent speakers upon subjects that are of interest to the members of the section as well as to the public. Mr. W. B. Woodland, who has charge of publicity matters, very happily co-operated with Dr. MacLean, so that the season's programme has been attractive in every respect. Good reports of the meetings have been published in the local papers. *La Press* is also giving good reports through the activity of the French Section, of which Prof. P. P. LeCointe is chairman.

The winter's programme to date has been:—*October* 29, 1923.—"Serums," by Mr. F. A. Bert. *November* 19, 1923.—"Chemistry as a National Asset," by Dr. C. T. Herty, of New York. *December* 17, 1923.—"Nitrogen Cycle," by Dr. G. H. Baril; "Food and Drug Control in Canada," by Mr. Aime Valin, Dominion Analyst. *January* 21, 1924.—"Forest Fire Prevention." A symposium at which Mr. Ellwood Wilson, Manager of Forestry Division of the Laurentide Co., and Mr. Robson Black, Manager of the Canadian Forest Association, were the chief speakers. The speeches and discussion were broadcasted from the Chemistry Building of the McGill University.

At the February meeting Mr. G. E. Saunders will speak on "Insecticides and Fungicides."

CHEMICAL SOCIETY

The President, Prof. W. P. Wynne, who occupied the Chair at an ordinary meeting held on Thursday, February 7, 1924, reminded Fellows that on February 28, at the Institution of Mechanical Engineers, Storey's Gate, S.W. 1, Prof. J. Joly would deliver the Hugo Müller Lecture, the subject being "The distribution of the radioactive elements in the rocks."

He further announced that the Bureau of Chemical Abstracts, in carrying out their policy of co-ordinating the production in this country of abstracts of papers in both pure and applied chemistry, had appointed Mr. T. F. Burton to be Chief Editor; abstracts in the various sections would also come under the review of Assistant Editors, as follows:—Dr. H. M. Dawson (General and Physical), Mr. A. A. Eldridge (Inorganic and Analytical), Mr. W. E. Garner (General and Physical), Mr. H. J. Page (Biochemistry), Dr. E. H. Rodd (Organic-aromatic), Mr. A. Shonk (Applied), Dr. E. E. Turner (Organic-heterocyclic), and Dr. H. Wren (Organic-aliphatic). Mr. Greenaway's unique experience would fortunately still be at the disposal of the Bureau.

The following paper was read by Mr. W. F. K. W. Jones:—

The activity of hydrogen ion in aqueous solutions of hydrofluoric acid. W. F. K. W. Jones and L. J. Hudleston.

THE e.m.f. of cells of the type H_2 | HF | KCl (sat) HgCl | Hg have been measured with concentrations of the acid ranging from 0·030 to 1·55 N. From these measurements, assuming that the potential at the liquid junction has been annulled by the saturated potassium chloride solution, the activity of the hydrogen ion of the acid has been calculated at these concentrations, and the results have been compared with the concentrations of the hydrion calculated by Davies and Hudleston from experiments on conductivity and transference number. The two sets of values agree within the limits of experimental error up to 0·4N solution, after which the activity is found to be materially higher than the concentration. The question as to whether the discrepancy is genuine, or due to a potential difference at the liquid junction is left open.

Mr. Jones agreed with Dr. Irvine Masson's suggestion that it might be possible for mercury to find its way to the electrode by diffusion through the platinum contact.

Dr. N. V. Sidgwick then dealt with the substance of two papers:—

The solubility of the aminophenols. N. V. Sidgwick and R. K. Callow.

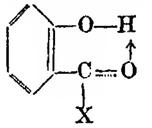
THE solubility-curves of the isomeric aminophenols in water, and in benzene, were determined, and their volatilities were compared. Only the *meta*- compound forms two layers with these solvents; with water, the two-liquid system is metastable, and lies 60° below the solid-liquid curve. The critical solution temperatures are: in water, *ortho*- (54°), *meta*- (1·9°), *para*- (25°); in benzene, *ortho*- (28°),

meta- (122·3°), *para-* (37°). Values in brackets are calculated from the slope of the solid–liquid curve. The volatilities are in the order $o > m > p$.

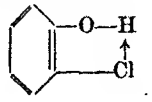
The aminophenols are abnormal, but their abnormality is not of the usual type; the *meta* compound is more soluble in water, and less soluble in benzene than would be expected.

Abnormal benzene derivatives. N. V. Sidgwick and R. K. Callow.

This paper summarises and discusses the results of a series of investigations on this subject (*T.*, 1915, **107**, 1202; 1920, **117**, 389, 396; 1921, **119**, 979, 1001, 1013; 1922, **121**, 1844, 1853, 2256, 2263, 2586; 1923, **123**, 2813, 2819; and the preceding paper). Abnormality (large differences between the isomerides in vapour pressure, and in solubility in the liquid state) requires: (1) that there should be two active substituents (such as Cl, NO_2, OH, etc.) on the nucleus; (2) that one of these should be: (*a*) OH; (*b*) NH_2 or substituted NH_2; or (*c*) CO_2H. The nature of the abnormality is different in cases (*a*), (*b*) and (*c*). With (*a*) the phenols, the *ortho*-compound is always more volatile, more soluble in benzene, and less soluble in water, than the *meta-* and *para-*, which resemble one another closely; that is, the *ortho* is far less polar (probably less associated). Comparison of the properties of normal and abnormal groups shows that the abnormality is mainly in the *ortho*-series. On combining these results with the cryoscopic work of Auwers (*Z. physikal. Chem.*, **18**, 595, **30**, 300, **42**, 513), it appears that the introduction of an active group into a phenol (1) in the *ortho*-position, makes it highly non-polar (2) in the *meta-* and *para-* makes it rather more polar, while (3) if it is introduced into the solvent, then in this solvent, the *para*-compounds appear to be less associated. All these facts can be explained by supposing that an active group is one which can co-ordinate with the hydroxyl hydrogen. (1) In the *ortho-* position it will form a stable ring of the types I (with NO_2, CHO, CO_2H, CO_2R, etc.), and II (with Cl, OCH_3, OH, etc.):



I



II

(2) In the *meta-* or *para-* positions it cannot do this, but will join to the hydroxyl of another molecule (though to a less extent) increasing the association or polarity of the phenol. (3) In the solvent it will co-ordinate with a *m-* or *p*-substituted solute, thus diminishing its association. This explains the non-polarity of the *ortho-* series, and the absence of compounds of *o*-nitrophenol with amines, as well as the fact that in an *o-p*-di-substituted phenol the influence of the *ortho-* substituent predominates. The behaviour of the acids and amines shows many differences from that of the phenols, and from one another which we cannot explain. The acids cannot form stable 5- and 6-ring compounds; the amines, though the formula admits of this, do not seem to co-ordinate in this way unless they are negatively substituted (chloro- and nitro-anilines).

Professor T. S. Moore referred to similar formulæ which had been put forward by Hantzsch, *e.g.*, in the case of ethyl sodioacetoacetate. Mr. W. E. Garner asked whether the differences in solubility extended to dinitro-compounds. Mr. H. Hunter enquired whether, in the case of the sodium salt of *o*-nitrophenol, where a colour change was observed, co-ordination ought not to occur even more strongly. With reference to the neutral character of the methyl group, Dr. J. Kenyon cited the reduction of one or other of the nitro-groups of 2:4-dinitrotoluene by different reducing agents, and asked whether the facts harmonised with the postulation of the *ortho*-compound being less polar. The President asked if the distance between the nitro- and the *p*-hydroxyl group was greater than the distance between two molecules.

Dr. Sidgwick, in reply, said that although Hantzsch had suggested similar ring formation, their view was that this should occur only in the *ortho*-series, whereas the chromoisomerism occurs also in the *meta-* and *para*-series. Internal salts, mentioned by Dr. P. May, could not be regarded as ring compounds, but as positive and negative ions forming part of the same molecule. According to the author's results, a dinitrobenzene (having no hydrogen atom in a side chain) should be normal. In the co-ordinated ring the hydrogen [or metal] is joined by non-polar links; if it is replaced by a metal, this may be ionised, destroying the ring and changing the colour. The difference in boiling point of 20° between *o-* and *p*-nitrotoluene suggested that there may be some co-ordination of the nitro-group to the hydrogen of the methyl group, which is known to be very mobile; this might explain the influence of the methyl group on the reducibility of the nitro-group. Dr. Sidgwick was unaware of any *X*-ray measurements of these substances, but it was assumed that the nitro-group of one molecule could get as near to the hydroxyl group of another as the OH- is to the NO_2- in o-nitrophenol.

Professor J. C. Philip discussed:—

The conductivity and ionisation of solutions of potassium iodide in nitromethane. By J. C. Philip and H. B. Oakley.

Much yet remains to be done in the investigation of the electrical properties of non-aqueous solutions. The present work is a study, for a given solute in a given solvent, of the bearing of the three factors—(*a*) temperature; (*b*) viscosity; (*c*) concentration—on conductivity and ionisation. The solutions examined were those of potassium iodide in nitromethane at dilutions up to V=10,000 and over the temperature range 0–85°. In work on the conductivity of non-aqueous solutions much uncertainty arises in connexion with the evaluation of Λ_∞ and large discrepancies exist between the figures reached by different investigators. One method of extrapolation much used hitherto is based on the cube root formula $\Lambda_\infty - \Lambda = a\sqrt[3]{c}$ (compare Philip and Courtman, *T.*, 1910, **97**, 1261), but the measure-

ments recorded in the present paper indicate that the linear relationship between the equivalent conductivity and the cube root of the concentration ceases to be valid at the highest dilutions. An attempt has accordingly been made to arrive at the value of Λ_∞ for the various temperatures by Washburn's method (*J. Amer. Chem. Soc.*, 1918, **40**, 122), which, as is well known, assumes the validity of the mass action law at extreme dilutions. From the values of Λ_∞ obtained in this way the values of α, the degree of ionisation, have been worked out for the concentrations employed at each of the experimental temperatures. It is found that α decreases markedly with rise of temperature. At the dilution $V=200$, for example, α diminishes from 0·82 at 0° to 0·76 at 85°. Measurements of the viscosity η of nitromethane were carried out at the same temperatures as those at which conductivity determinations were made, and it was found that the value of Λ_∞ increased with rising temperature in almost exact proportion to the fluidity. The value of the product $\Lambda_\infty \times \eta$ is 0·76 at 0° and 0·73 at 85°.

Mr. W. F. K. W. Jones said that in recent work on methyl alcohol, carried out under General Hartley's direction, the square root formula was found to hold; the cube root formula did not hold, and Washburn's formula gave different results.

Professor Philip said that the cube root formula was clearly useless for practical purposes; it was desirable to investigate the matter at higher dilutions. The correction for the conductivity of the solvent at the highest dilution employed was about 3·5 per cent.

Professor Philip also gave an account of work on :—

The solubility of anilinesulphonic acids. By J. C. Philip and R. S. Colborne.

THE aniline- or bromoanilinesulphonic acids are characterised by extreme readiness to separate from their aqueous solutions in unstable forms, which in some instances are sufficiently persistent to permit the determination of their solubility at a series of temperatures. The stability relationships of the various forms have been studied on these lines for aniline-*o*- and -*m*-sulphonic acids and *p*-bromoaniline- *o*- and -*m*-sulphonic acids, whilst a few observations have been made on the behaviour of the corresponding *p*-chloroanilinesulphonic acids. Perhaps the most interesting case under investigation is that of *p*-bromoaniline-*m*-sulphonic acid. When this compound separates from aqueous solution, either on cooling a solution saturated at a higher temperature, or by the addition of mineral acid to a solution of its sodium salt, it yields a felted mass of crystals of a labile monohydrate. When the separation is complete, the containing vessel can be inverted without loss of liquid. On standing, the more stable and therefore less soluble anhydrous acid gradually forms at a number of nuclear points, and the felted mass is ultimately replaced by a small quantity of compact crystals at the bottom of the vessel. The changes observed resemble those described by Chattaway for the production and transformation of the labile hexahydrate of calcium tartrate. This same acid in the anhydrous form is obtainable in two enantiotropic modifications—monoclinic and rhombic—although it is only above 100° that the rhombic variety is the stable one. For the whole range of temperature—up to 85°—over which determinations were made the rhombic form was found to be the more soluble.

Prof. C. S. Gibson mentioned that he had observed similar behaviour in the case of an organic substance in carbon tetrachloride solution.

Mr. R. S. Colborne said that the meta-derivative, as was observed by Dr. Sidgwick in other cases, most readily formed supersaturated solutions. It was possible that the extreme instability of the hydrates of the anilinesulphonic acids is connected with their amphoteric character, the hydrated forms being the "acid" type whilst the anhydrous acids possess an internal salt structure.

Dr. T. A. Henry described experiments on :—

Mercuration of nitrohydroxybenzaldehydes. By T. A. Henry and T. M. Sharp.

THE mercury derivative of *m*-hydroxybenzaldehyde previously described (*T.* 1922, **121**, 1056) is now shown to be 2-acetoxymercuri-3-hydroxybenzaldehyde

$$CH_3.CO.O.Hg.C_6H_3(OH).CHO.$$

The three nitrobenzaldehydes do not mercurate even on boiling in solution with mercuric acetate for three weeks. Under similar conditions 3-nitro-4-hydroxybenzaldehyde mercurates in position 5, as is shown by the conversion of the resulting mercury compound into 5-iodo-3-nitro-4-hydroxybenzaldehyde by the action of iodine. 6-Nitro-, 4-nitro-, and 2-nitro-3-hydroxybenzaldehydes all yield both mono- and di- mercurated compounds, which can be separated by fractional crystallisation from appropriate fatty acids, the only media in which they are conveniently soluble. They react with iodine in potassium iodide, forming iodo-compounds in which iodine has replaced mercury residues in the normal fashion. Bromine, on the contrary, shows abnormal behaviour with them. Thus whilst 2:4-dihydroxydimercuri-6-nitro-3-hydroxybenzaldehyde yields the expected 2:4-dibromo-6-nitro-3-hydroxybenzaldehyde, the latter is also formed in yields of over 80% by the action of bromine on the dimercurated derivatives of the 4-nitro- and 2-nitro-3-hydroxybenzaldehydes. Of the possible explanations of these latter results: (1) that the starting materials were impure; (2) that the original compounds are not correctly represented by the formulæ assigned to them; or (3) that a re-arrangement of groups within the molecule takes place, involving the migration of a nitro-group from an *ortho-* to a *para-* position with respect to the hydroxyl group, the third is shown to be the only one tenable. Results of bactericidal trials with the mercury compounds are summarised.

Mr. T. M. Sharp gave some additional details regarding the evidence on which the conclusion that migration occurs was based.

ROYAL MICROSCOPICAL SOCIETY

Sir Robert A. Hadfield, Bart., F.R.S., presided at a meeting of the Industrial Applications Section on January 23, and, in the course of his address, gave the Society a cordial invitation to visit the laboratory at his works in Sheffield. It was largely through the efforts of the microscopist, he said, that they had been able to fathom, at any rate to some better extent than previously, the mysteries of the many combinations or compounds formed in alloys of iron with other elements. He believed this country would continue to hold its own in this branch of science, provided the same energy was displayed as during and since the war. He hoped that the Society would extend its influence in the various districts where the study of metallurgy was so necessary. One point which had very much interested him with regard to the microstructure of steel was a fuller and more careful study of the effects produced on the physical properties of various kinds of steel by what might be termed "cold treatments" in contradistinction with "heat treatments," but which did not bring chemical action into play. A comparatively new competitor was coming into the field which in one sense might be thought to supplant the work of the microscopist and the metallographer. He referred to X-ray analysis of metals. But there was still ample room in these branches of research for further and supplementary work. It was impossible to prophesy the extent to which X-rays would be used in the future, but a great advance in research was inevitable.

Captain J. W. Bampfylde, A.R.S.M., F.R.P.S., read a communication on "Some Failures in Steel as Revealed by the Microscope and Recorded by Photography." The main lines of research employed in the investigation of failures in steel were chemical analysis, physical tests, macroscopical and microscopical examinations. The object of the communication was to show that the last two named were most important factors in such examinations, and that much evidence might be brought to light by using the microscope, the attainment of which might otherwise be almost impossible. On account of the fact that macroscopical and microscopical work were so closely interwoven, a few of the methods employed in the former were briefly described. Three cases of failure in railway material were dealt with and the manner in which their causes were investigated by the above methods were described. In conclusion, a new form of metallurgical objective in which oblique light from all sides was employed was discussed. This was made possible oven with high-power objectives such as the 2 mm. oil-immersion. Photomicrographs taken with these objectives were shown.

Mr. H. B. Milner, M.A., A.M.I.P.T., read a paper on "The Use of the Microscope in the Petroleum Industry." The wonderful strides made in the evolution of the petroleum industry had provided one of the most fascinating romances of modern commerce, particularly if the position to-day was compared with that of, say, fifteen years ago. To a large extent this rapid progress had been the result of development in the technique of production and refining, and in both branches microscopy had played an important part. Production implied, apart from drilling and engineering operations on an oilfield, all the geological work essential to the exploration and location of oil-bearing territory and had come to be more and more dependent on the precise methods of micropalaeontology and micropetrology, especially the latter. Similarly the microscopical investigation of impregnated (bitumenised) rocks was of great practical importance. On the refining side the microscope was being employed in a number of specialised operations including those concerned with decolorisation of oil and the use of certain filters such as fuller's earth, "floridin," charcoal and bauxite, whilst a study of oil-films and oil-blending was greatly facilitated by the microscope. Lubricants and greases, including graphite lubrication, presented a variety of practical problems of both manufacture and use, *e.g.*, in connexion with fibre and other "loaded" greases; these were more readily solved by means of the microscope than in any other way, as was the case with problems arising from the production of other impregnated textile materials used for roofing, insulation and sheathing purposes. Asphaltic rubber and asphaltic cement were two further commodities whose manufacture and use gave rise to difficulties often met satisfactorily by microscopical enquiry.

THE SIR JOHN CASS TECHNICAL INSTITUTE

The Annual Distribution of Prizes at the Sir John Cass Technical Institute was held on January 30, 1924, when the prizes and certificates were distributed by Sir W. H. Bragg, K.B.E., F.R.S., Director of the Royal Institution.

The Chairman of the Governing Body, the Rev. J. F. Marr, M.A., in giving a summary of the work of the Institute, stated that an outstanding characteristic of the past session had been the earnestness of the students and the regularity of their attendance. The work done had undoubtedly been of great value to the students, and through them to the industries with which they were associated. Altogether, 41 students had been successful at the examinations of London University, five having obtained the degree of M.Sc. by research carried out at the Institute. Twenty-two students had been engaged in research work during the session and 17 original investigations had been published, bringing the total number of papers issued from the Institute to 137.

Following the distribution of the awards, Sir William Bragg delivered an address on "Research Work and Its Applications." The address was devoted particularly to the nature and objects of research. Emphasis was laid on the new era of research work marked by munificent gifts such as those of Sir Alfred Yarrow to the Royal Society, of the Rockefeller Trustees to University College, and by the stimulus given by the Department of Scientific and Industrial Research. Research work, it was pointed out, brought out self-reliance, the faculty of

selection and judgment of evidence, and developed a sound study of previous investigations. The valuable faculty of selection was one of the most important lessons to be learnt in connexion with research. A good research student was likened to a fire which, on a match being put to it burned without being touched again. The research worker should never try to convince others of the value of his work, but leave them to discover this themselves. Those who devoted their time to research were always hoping to add something to human knowledge and to human interest. It was our duty and our gain always to explore and the spirit of research therefore was something which we should try to foster and incorporate in the nation's life. Concluding, Sir William Bragg said that research was not a religion, but the act of one. It implied a certain faith in the beauty and the purpose of the Universe; that whatever there is in the world was really meant for us to see if only we can see it.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

"The Chemistry of the Photographic Plate" was the subject of the Presidential Address delivered by Prof. G. T. Morgan, F.R.S., on January 21. There was a large attendance of graduates, research workers and science students. In an historical introduction to the photochemistry of silver salts, Prof. Morgan referred to the early experiments made by Fabricius (1556), Scheele (1777), and by Wedgwood and Davy on the action of light on the silver halides (1800–1802). The production of a permanent picture was achieved by J. N. Nièpce (1813), who noticed that light rendered insoluble the bitumen of Judea, whereas the unexposed portion was removed by organic solvents. Daguerre (1835) introduced the method which still bears his name, Daguerrotype. This now obsolete process, which was practised for nearly twenty years, resembled the modern processes in being dependent on the formation of a latent image, which, in this case, was developed by mercury. The discoveries by Talbot and Herschel (1839) led to the improved Calotype or Talbotype process (1841), a procedure which involved the use of sensitisers and developers. Herschel's contributions were of fundamental importance, and included the employment of hyposulphite (thiosulphate) for fixing, and the discovery of the blue print and platinotype processes. The wet-plate collodion process discovered by Scott Archer (1851) had a considerable vogue until superseded by the dry plate or emulsion process introduced by Maddox (1871) and improved by Wratten (1876). The action of light on the silver halides was discussed with special reference to current hypotheses concerning the nature of the latent image. A practical demonstration was given of the chemical changes involved in the use of sensitisers and developers. Reference was made to the chemical constitution of organic developers and of the synthetic dyes employed in the production of panchromatic plates. The chemical processes involved in fixing, intensifying, printing and toning were also explained by means of specially-devised experiments carried out by Mr. C. P. Proctor. The more modern applications of the platinotype and carbon printing processes were reviewed, and the address concluded with a brief reference to colour photography.

SOCIETY OF PUBLIC ANALYSTS

The Annual General Meeting was held at the Chemical Society's Rooms, Burlington House, on February 6, when the president, Mr. P. A. Ellis Richards, delivered his annual address. The following were elected as Officers and Council for the ensuing year:—*President:* G. Rudd Thompson. *Past-Presidents* (Serving on the Council): Leonard Archbutt, A. Chaston Chapman, Bernard Dyer, Otto Hehner, P. A. Ellis Richards, Alfred Smetham, E. W. Voelcker, and J. Augustus Voelcker. *Vice-Presidents:* S. F. Burford, F. H. Carr, and A. More. *Hon. Treasurer:* Edward Hinks. *Hon. Secretary:* E. Richards Bolton. *Assist. Hon. Sec.:* R. G. Pelly. *Other Members of Council:* F. W. F. Arnaud. H. Ballantyne, E. T. Brewis, R. T. Colgate, R. L. Collett, J. C. Drummond, S. Elliott, E. M. Hawkins, H. F. E. Hulton, A. E. Parkes, A. R. Tankard, and J. F. Tocher.

Mr. C. Ainsworth Mitchell, M.A., then read a paper on "Osmium Tetroxide as a Reagent for the Estimation of Tannins and their Derivatives." Osmium tetroxide (the osmic acid of the microscopists) can be used as a sensitive reagent for tannins and their derivatives, being capable of detecting, *e.g.*, 1 part of gallic acid in 3,000,000. The coloration ranges from red-violet in dilute solutions to violet-black in concentrated solutions. Unlike the author's ferrous tartrate reagent, osmium tetroxide gives similar colorations with both the pyrogallol and catechol tannins. For quantitative work the ordinary 1 per cent. microscopic stain is diluted with 10 parts of water and a solution of 0·1 g. of pure pyrogallol, catechol, or gallic acid is used as the standard. The colorations produced by catechol and pyrogallol are relatively proportional to their molecular weights and the same relationship applies to the colorations given by protocatechuic acid and catechol, but gallic acid gives a relatively more intense coloration than pyrogallol. The method affords a convenient means of estimating the pyrogallol and catechol tannins together, in terms of catechol, pyrogallol, or gallic acid, and it has been applied to the analysis of various products such as extracts of wood, commercial saw-dust intended for curing fish, coffee, and hops.

Apparatus for fat extraction and solvent recovery was demonstrated by Mr. S. A. de Lacy, A.I.C. The apparatus consists of an extraction vessel with a three-holed stopper, one hole for the special key device, one for the attached condenser, and one for the tube to lead away the vapours of distilled solvent. The material to be extracted is suspended in a container supported in the extraction vessel, and the key device can be operated from the outside to close either the opening to the condenser or to the side tube, in turn. This device is essentially a thick circular rod attached to an oval platform with a drip point projecting from the lower surface.

ACADÉMIE DES SCIENCES

On January 21, Prof. Le Chatelier presented a paper by Monsieur Le Beau on the distillation of coal. Previously Monsieur Le Beau had shown that when distilling anthracite a large quantity of hydrogen was given off. The present work related to gas coals containing from 30 to 35 per cent. of volatile matter. By carefully fractionating the distillate he has found that hydrogen and the higher homologues of methane are of more importance as constituents of gas than was thought. Thus, the higher homologues of methane may be present to the extent of 10 per cent. These differences were ascribed to the fact that formerly all the compounds of the saturated series were generally estimated as methane, which was thus given too much importance.

Monsieur C. H. Lallemand presented a note by Monsieur Bochet who attempted to show that the theoretical argument which led Van der Waals to enunciate the law of "The Corresponding States of Fluid," lacked a sound basis. Bochet claims that by comparing the properties of water and of carbonic acid differences are found which are incompatible with the truth of the law.

During the meeting on January 28, Monsieur Béhal communicated the results of a study by Monsieur Freundler, on "The Iodine Content of Algæ," a study not merely of theoretical interest, but which may lead to an increase in the production of iodine. When estimating the iodine in *Laminaria* by various methods, Monsieur Freundler found that the element was present in greater amount when the algæ had been kept in the dark, or immersed in a saline solution. By combining these two factors the yield of iodine was almost doubled. Monsieur Gentil gave some new information on the magnetic anomalies observed by Prof. Lazarev in the Koursh region of Russia.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

On January 30, the Metallurgical and Mineral Industry Group heard, under the chairmanship of Mr. Gall, a paper by Mr. Boutigny on "Aluminothermy." After discussing the important part played by electric energy in the heavy chemical industry, Mr. Gall showed how the electrolytic soda process had become the necessary ally of the ammonia process in order to compete with the Leblanc process, which consumed so much coal. He then discussed aluminothermy and pointed out how great a heat arose from the combustion of aluminium, owing to its great affinity for oxygen. Under certain thermo-electric conditions aluminium would reduce metallic oxides to form alumina, freeing the metal and liberating a great amount of heat in yields sufficient for industrial purposes. The state of division of the mixture of met[illegible] oxide and aluminium powder was an imp[illegible]tor, which might increase or moderate the [illegible] of the reaction. In practice the state of divis[illegible] was designed to enable the operation to be carried out with safety. The most important reaction was that of iron oxide $F_2O_3+Al_2=Fe_2+Al_2O_3+182$ calories, a reaction which found numerous applications in welding. Other reactions of less industrial importance were not without interest and found application in metallurgy when metals free from carbon were necessary. In this field aluminothermy competed with the electric furnace, and the special steels containing chromium, nickel and titanium were the proof. An interesting field of research lay open for aluminothermy, a field first discovered by Moissan and realised by Goldschmidt.

THE BRITISH SCHOOL OF MALTING AND BREWING

The annual dinner of this School was held on February 9, at the Midland Hotel, Birmingham. The company included about forty. Professor Arthur R. Ling occupied the chair.

The usual loyal toasts having been duly honoured, Mr. Walter Scott proposed the chairman and the Brewing School. In the course of a humorous speech he said that his toast could be divided into two parts, the animate and the inanimate. He referred to the falling off in the numbers attending the dinner and suggested that the company should consider what steps could be taken to revive its interest. Professor Ling said that it was to be regretted that neither Mr. Butler, Mr. Field (the External Examiner) or any other member of the board of management was present. He was pleased to say that the School was progressing favourably and that a comparatively large amount of research work was being turned out. During the past session there had been published from the department ten papers. They had to thank Mr. H. E. Field for presenting the School with a potentiometer, whereby the concentration of hydrogen ions could be measured. This was one of the factors which would probably be found of great utility in the future in deciding the stability of beer.

Mr. F. J. Paton, one of the honorary secretaries, in proposing the past students, said that he welcomed the past students to the dinner as it was essential that the Brewing School as a whole should be able to meet together. All its students had a common tradition and this constituted a strong tie between the past and present students. Mr. W. E. Showell replied.

The toast of the present students was given by Mr. F. A. Smith and replied to by Mr. W. S. Shaw in the absence of one of the honorary secretaries, Mr. S. N. Yeomans.

The Chairman then proposed a vote of thanks to the honorary secretaries for organising the dinner.

After the dinner the company became an informal committee, and the question was discussed as to what steps should be taken to induce a larger number of past students to attend the dinner. Among other things the point was raised as to whether it would be preferable to hold the dinner in London instead of in Birmingham and ultimately it was decided, at any rate for the next year, to continue to hold the dinner in Birmingham. A large committee, representative of past students in various districts, was then formed, Mr. S. Raine being appointed secretary.

CORRESPONDENCE

ADVANCE PROOFS OF PAPERS

SIR,—The provision of advance proofs of Prof. Hinchley's paper on Monday last rendered an excellent address even more valuable and gave opportunities for a useful discussion, which would otherwise have been lacking, and I am sure that practically all the members of our Society will agree with me that the provision of advance proofs of papers is much to be desired.

I quite realise that this is impossible in all cases, but I suggest the following idea for the favourable consideration of the Council. Whenever the author of a paper to be read before any section of the Society considers his communication of sufficient importance, he should submit the manuscript to his local committee in sufficient time to allow their acceptance of it, and also of its acceptance by the Publication Committee and the Editor. If accepted for publication it could be set up at once and a sufficient number of galley proofs provided at comparatively little extra cost, and these should be available on request by any member desiring them.

I would further suggest that the discussion of papers should not be confined to the occasion on which it is read, but continued by both oral and written contributions at subsequent meetings of the Section. This would, I am sure, lead to a much better discussion, and would bring to our notice many points otherwise omitted. To complete the scheme it would, of course, be necessary that the discussion, if bearing on the subject, should be published in full. In your interesting paragraph in the last issue you rightly say that the reading of papers to one another can be overdone. It both can and is, but good discussions or debates on useful and interesting subjects can only be productive of good, both to the debaters and listeners.

I trust, Sir, that some way may be found to ventilate this idea, and, if possible, to adopt it with such modifications as the Council, in its wisdom, may consider advisable.—I am, Sir, etc.,

W. H. COLEMAN

Chemical Industry Club,
2, Whitehall Court, S.W. 1
February 5, 1924

PERSONAL AND OTHER NOTES

Prof. J. Joly will deliver the Hugo Müller lecture of the Chemical Society on February 28, at 8 p.m., in the Hall of the Institution of Mechanical Engineers, Storey's Gate, S.W. 1.

The jubilee of the Physical Society of London is, states *Nature*, to be celebrated from March 20 to 22, March 21 being the fiftieth anniversary of the meeting of the Society.

Prof. G. H. Hardy has been elected president of the National Union of Scientific Workers for the year 1924, and Dr. J. W. Evans has been elected president of the Research Council.

Amongst Mr. Baldwin's resignation honours mention may be made of the baronetcies conferred on Sir O. Beit, for services rendered to the Imperial College of Science and Technology, and on Mr. W. H. Barber, a generous benefactor to the University of Birmingham.

At a meeting of the Faraday Society to be held in the Rooms of the Chemical Society on February 18, at 8 p.m., Principal A. P. Laurie will put forward some suggestions for a magnetic theory of valency based on the model of an atom which he has recently devised. The lecture will be illustrated by lantern slides.

Monsieur R. P. Duchemin, who was recently appointed an officer of the Legion of Honour, has been elected president of the Union des Industries Chimiques. Other officers of the Union are MM. Michel, Roche, Lheure, and Bezançon, vice-presidents; M. Langois, treasurer; M. Saunier, assistant treasurer; MM. Agashe, Guieu, Le Play, Thesmar, secretaries; MM. Poulenc, Huillard, Etienne, Binoche, Bisset and Herr, members of council.

* * *

From Paris the deaths are announced of Monsieur G. Dumont, a past president of the Société des Ingenieurs Civils, and Monsieur Lavaurs, formerly managing director of the Cie. des Mines de Courrières.

Prof. George Quincke, described as the nestor of German physicists, and professor of physics at Heidelberg until 1907, has died at the age of ninety. Other deaths from Germany include the names of Prof. E. Dieckhoff, director of the Qualitative and Pharmaceutical Division of the Chemical Institute of Karlsruhr; Th. Melzbach, director of the paper factory of that name; and Dr. L. Schroeder, director of the Accumulatorenfabrik A.-G.

Dr. Julius Szilagyi, professor at the Budapest Technical Hochschule, who died recently at the age of sixty-four, had done valuable work on the scientific control of the alcohol industry.

SOUTH AFRICA

Discovery of Platinum in the Waterberg District

The recent discovery of platinum in lode form in the Waterberg District of the Transvaal has aroused a good deal of interest on account of the unique nature of the find, and the great economic possibilities of it to the Union.

To date, 99 per cent. of the world's output of the platinum metals has been recovered from alluvial placers, the principal deposits being in the Central Urals in Russia, where the pre-eminent matrix of the platinum is dunite, an ultrabasic rock consisting essentially of olivine and chromite. The minor deposits of platinum metals in the other parts of the world are almost wholly in rocks of a basic or ultrabasic type, or in placers derived from the weathering of such rocks. It is interesting to note that there appears to be a distinct relationship between platinum and nickel or chromite, and that in the smelting of the nickel-copper ores of Sudbury the matte in 1916 (80,000 tons) contained 50,000 oz. of platinum and palladium. One of the smelting companies states

however, that the recovery of platinum metals was only 8 per cent. of the total contained in the matte. In Southern Africa the occurrence of platinum metals (apart from the osmiridium in the Rand banket) has been noted in a dyke of norite in the Gwelo District of Rhodesia and in the Somabula (Rhodesia) diamond-bearing gravels. In the Cape Province, platinum is known to exist in the copper-nickel ores of the Insizwa Range. In the Transvaal, chromite ores in Rustenburg and Lydenburg contain traces of platinum, and its presence has also been known in the norites of the Northern Transvaal.

Platinum in vein material of an acid type has been recorded at a few isolated places only, but except for one occurrence in Nevada, these finds were of very small extent, and only of academic interest. It is evident that the recent discovery in the Transvaal of platinum in a quartz lode in acid country rock extending over a considerable distance is quite unique. The lode is in the Waterberg District, about 100 to 110 miles north of Pretoria, and consists of a brecciated quartz filling with angular inclusions of felsite. Up to the present no particular type of lode matter has been found to carry platinoid values. The lode itself varies in width from one to 30 feet. Active prospecting in two areas showed platinum in the outcrop. At "Doornhoek" the lode was found to be 30 feet wide, but the values so far have been very low. At "Rietfontein," however, where the lode can be traced continuously for 3000 yards, the outcrop has been trenched and partly stripped for a distance of about 400 yards along the strike, the average content of platinum metals being 23·3 dwts. over 54 in. in width. The platinum in the ore is generally very fine, though nuggety pieces are seen. —(*J. Chem. Met. and Min. Soc. S. Africa, Sept.*, 1923.)

GENERAL

The Mass-Spectrum of Indium

In a letter to *Nature* of February 9, Dr. F. W. Aston states that he has examined the mass rays of indium (at No. 49, At. Wt. 114·8), using an anode containing the fluoride, and found that the mass-spectrum of the element showed only one line at 115. This, measured against I^{127} and Cs^{133} showed no deviation from the whole-number rule. Its intensity was insufficient to rule out the possibility of a small percentage of a second isotope, but, in the absence of evidence on this point, Dr. Aston considers that indium is best regarded as a simple element of mass number 115, as predicted by Russell. This, states Dr. Aston, was "the only success worth recording," owing partly to the capricious behaviour of the apparatus for producing accelerated cathode rays, and partly to the unfavourable properties of the elements remaining to be analysed.

Metallurgy in Luxemburg

The production of iron and steel in Luxemburg has risen from 1,685,700 tons, and 1,394,103 t., respectively, in 1922, to 1,406,666 t. and 1,197,739 t., in 1923. By far the larger proportion is produced by the Thomas process, Martin steel and electric steel being still limited in quantity.

REVIEW

INDUSTRIAL ALCOHOL. *By* J. G. MCINTOSH. *Second edition, revised and enlarged. By* H. B. STOCKS, F.I.C. *Pp.* xii+400. *London: Scott, Greenwood and Son,* 1923. *Price* 12*s.* 6*d. net.*

The first edition of this book appeared in 1907, and the present volume is practically the same book, with the addition of three short chapters dealing with alternative sources of alcohol which have been opened up in recent years, together with various other additions, but few corrections. The reviser would have been well advised to rewrite entirely the older portions of the book. However accurately it may have represented Continental distillery practice of thirty or forty years ago, it is now so out of date as to be of little more than historical interest. In the sections dealing with the fermentation of beets, grain, molasses, wine, etc., and the distillation and rectification of alcohol, many passages bear evidence of literal translation from standard French works of the latter part of last century, and the frequent occurrence of such terms as "phlegm," "retrogradation," "leaven," to say nothing of "sodic ethylate," "oenanthic vapours," etc., emphasises the archaic character of the work. Few of the alcohol lighting and heating appliances figured in Chapter XIV are now to be found outside museums, and the statistics relating to the production of alcohol are, with few exceptions, carried no further than 1912. The language of the author is often obscure, and in places quaint. We read "There are three principal classes of substances in phlegm . . . All other kinds are bastard lots"; and on page 60 we learn the function of the "unique mother vat" in continuous fermentation.

Apart from the shortcomings of the older portion of the book, the reviser's additions are not free from serious omissions. No reference is made to Ricardo's important work on the use of alcohol in the internal-combustion engine, nor is mention made of the Power Methylated Spirits Regulations of 1921, under which alcohol is now being denatured and used for motor transport in this country. The synthesis of alcohol from acetylene, which attained considerable importance during the war, and which is being further developed on the Continent, is given less than 20 lines, with no indication of the nature of the chemical reactions involved. The "amylo" process, one of the most important developments of recent years, is referred to in only 7 lines. The theory of fermentation is confined to a short statement of Harden and Young's hexose-phosphate equation of 1910, but perhaps a fuller treatment of this subject is hardly to be expected in a work on industrial alcohol.

With all its faults the book is undoubtedly valuable, as giving a detailed account of the development of French distillery practice. The controversies which arose between Barbet and Guillaume as to methods of distillation and rectification are fully discussed, and the practical man cannot fail to find useful information in a book which deals exhaustively with the pioneer work of the older French distillers.

G. W. MONIER-WILLIAMS

REPORTS

REPORT ON THE ECONOMIC AND COMMERCIAL CONDITIONS IN THE DOMINION OF NEW ZEALAND, DATED JULY, 1923. *By* N. ELMSLEY, *Trade Commissioner, New Zealand. Department of Overseas Trade. Pp.* 60. *H.M. Stationery Office,* 1923. *Price* 2*s.*

The year now under review was one of recovery from the post-war depression. The trade returns in the last few years give little idea of the actual state of the country, but 1922 showed a more favourable trade balance than the previous year, while imports increased steadily consequent on the reduction of stocks accumulated in 1920.

During 1922-23 the wool industry recovered from the previous two bad seasons. In 1922, 914,094 bales, valued at £11,883,463, was exported. Most of this export took place before the rise in prices, so the figures do not indicate rightly the great improvement which took place during the year over the position in 1921, when 452,231 bales, valued at £5,221,479, was exported. Dairy produce is an important item of export. In 1922, 1,120,200 cwt. of butter and 1,161,196 cwt. of cheese were exported, valued at £9,041,554 and £4,686,850 respectively.

Imports in 1922 were valued at £35,012,561, and exports at £42,726,249. Pastoral industries are responsible for an overwhelming majority of the exports. Of the imports the United Kingdom supplied 52·25 per cent. in 1922, against 48·5 per cent. in 1921. The Dominion is now importing on the same scale as in 1914, and the United Kingdom is supplying about the same proportion as then, though there are still some articles which could be imported more largely from Britain; the increase customs preference accorded to British goods since the end of 1921 has no doubt helped greatly to bring about the recent increase in the proportion of these in the total imports. The items of import in 1922 included manufactured goods of animal origin, £41,641; oils, fats and waxes, £2,324,333; paints and varnishes, £370,552; stones and industrial minerals, £716,726; unmanufactured metals and ores, £331,577; manufactured metals, £4,249,178; machinery, £2,769,325; leather and substitutes, £475,385; earthenware, china and glass, £716,182; drugs and chemicals, £1,098,024; manures, £248,572.

REPORT ON THE ECONOMIC AND COMMERCIAL SITUATION OF AUSTRALIA, DATED JUNE, 1923. *By* S. W. B. MCGREGOR, *Senior Trade Commissioner of Australia. Department of Overseas Trade. Pp.* 83. *H.M. Stationery Office,* 1923. *Price* 2*s.* 6*d.*

The year under review was again one of great prosperity (*cf. Chem. and Ind.*, 1923, 107), and Australia seems to have suffered less than any other country from the war. The position of wool continues good, but wheat prices are down, and the reduction in the value of wheat exports led to an adverse trade balance. Cotton-growing is assuming some importance. The following quantities of metals were exported during 1922: silver, 11,746,295 oz. fine; lead, 130,187 t.; zinc, 159,414 t.; copper, 11,850 t.; tin, 2657 t.; pig iron, 83,533 t.; whilst £3,507,119 was realised from the sale of gold in 1922. Prospecting for oil has been continued, but at present the only useful sources of oil are shale beds, which are worked to some extent.

In the financial year 1922-23 imports amounted to £131,808,673 and exports to £117,913,083, giving an unfavourable balance as mentioned above. In 1921-22 the corresponding figures were £103,066,436 and £127,846,535. Of the imports in the latter period the United Kingdom supplied 51 per cent. and the United States 18 per cent. Some particulars are given of imports in 1923, with reference to home resources. The existing cement works in Australia are more than capable of supplying the demand but 44,969 t. was imported. About 90 per cent. of the cinematograph films imported, which were valued at £289,244, came from the United States. The figures for chemicals, drugs, etc., are for 1921-22, when the value of such imports was £3,553,377. Items of interest were tartaric acid, £29,354, and cream of tartar, mainly derived from the United Kingdom. Synthetic dyes were valued at £162,498, proprietary medicines, etc., at £513,000, perfumery and toilet preparations at £278,000. Imports of explosives in 1922-23 were valued at £202,758; some explosives are made in Australia.

Of the exports from Australia in 1921-22 the United Kingdom took 45·2 per cent., and other British countries 17·1 per cent.; both figures are somewhat less than in the previous year but more than before the war.

Although protected by heavy tariffs Australian manufacturing industries are making little headway. The reasons are the small home market and high costs of production and distribution which render export impossible.

Some account is given of the development for production of electric power of brown coal deposits in Victoria; 10 acres of brown coal have been exposed, and the main power-house is nearly completed. Hydro-electric development is going on in Tasmania and 63,000 h.p. is now available.

REPORT OF THE FOOD INVESTIGATION BOARD. *Department of Scientific and Industrial Research. Pp.* 60. *H. M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

The outstanding event of the year recorded in the report of the Food Investigation Board is the equipment of the Low-Temperature Research Station at Cambridge, at which work has already begun. It is interesting to note that the station intends to aim at an accuracy in its work comparable even with that of the National Physical Laboratory. Already the station has been used for the determination of the effect of cold on insulin and an account is given in the report of a promising development of the theory of the freezing of tissues. Work has also been carried out under the Board on the storage of apples, the preservation of fish, the chemical changes in meat during cold storage, and the chemistry of the ripening of fruit.

During investigation of "gas storage" the Fruit and Vegetables Committee found that the carbon dioxide used leaked at an unexpectedly high rate through the walls of the store, and experiments are in course at the National Physical Laboratory on coating materials to prevent this loss. The work on carbohydrate and nitrogenous autolysis of cold-stored meat is far enough advanced to show that, even at cold-storage temperatures, the glycogen content diminishes, the change being complete and comparatively rapid at high temperatures. Miss D. M. Moyle has worked out a method for estimating small quantities of succinic acid in muscle and Miss D. L. Foster has investigated methods for estimating glycogen. The production of brown methæmoglobin in frozen meat has been studied and the attempt is being made to correlate the chemical changes taking place in meat extract with the various phases in the growth of a single species of bacterium, viz., *Staphylococcus aureus*. Work done under the Engineering Committee includes research on the "time-lag" of thermometers, the absorption of moisture by insulating materials, the thermal and corrosive properties of ethyl chloride, and hygrometry. The investigation (under the Oils and Fats Committee) of the products of the hydrolysis of fats has been continued under the supervision of Principal J. C. Irvine, using a fat consisting essentially of tristearin, and various methyl ethers of glycerol have been prepared for reference, particularly trimethylglycerol, β-dimethylglycerol and $\alpha\gamma$-dimethyl glycerol. At Manchester, oleic acid and the synthesis of the higher unsaturated acids have been investigated. The formation of fat by yeasts is still being studied at the Lister Institute, interesting results having been obtained. Much time has been devoted, under the Canned Foods Committee, to the improvement of methods, *e.g.*, for distinguishing between primary, secondary and tertiary amines, and for estimating inorganic phosphate in the presence of organic matter.

COMPANY NEWS

SOUTH METROPOLITAN GAS CO.

The revenue account for the year 1923 shows a credit balance of £530,699, against £741,903 for 1922, and the balance brought forward was £234,986. Debenture interest and other fixed charges being met, the dividend of 5 per cent. has been paid on the preference stock, and the dividend for the year on the ordinary stock is 5¾ per cent. (against 5¼ per cent.). An allocation of £16,500 is to be made to the reserve fund (against nil), and the balance to be carried forward is to be increased by £1[illegible] to £254,510. The capital liability of the undertaking has been reduced during the year by the redemption of £147,420 five per cent. preference stock, issued in 1917. The balance of this stock will be redeemed in December next. The directors report an increase in the number of gas consumers, and in appliances used by them. The total receipts for the year amounted to £4,542,497 (against £4,891,620).

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The market shows signs of confidence and business seems to be settling down on a satisfactory scale in spite of the depressed state of the textile trade and unsettled labour conditions. There are no changes of price to be noted in any of the standard lines but in articles which are imported from the Continent values are continuing to rise. Formic acid is in better supply, the home-produced material being now available.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages included.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5½d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Business good.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

The demand for rubber chemicals remains somewhat slow.

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb., according to quality.

Antimony Sulphide, [illegible]—
Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow 1s. 11d. per lb.
Cadmium Sulphide .. 4s. per lb.
Carbon Bisulphide .. £24—£26 10s. per ton according to quantity.
Carbon Black .. .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride .. £55 per ton, drums free.
Chromium Oxide .. 1s. 3d. per lb.
Indiarubber Substitutes,
White and Dark .. 4d.—6½d. per lb. Fair demand
Lamp Black .. .. 40s. per cwt., barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. £10—£12 per ton, according to quality.
Thiocarbanilide .. .. 2s. 9d. per lb.
Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade and there appears a more healthy prospect in the charcoal market.

Acetate of Lime—
Brown .. .. .. £14 10s. per ton d/d. Demand active.
Grey .. .. .. £22 per ton.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. „ „ 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 5s. 6d. per gall. 60% O.P. Dull market.
Solvent .. .. 5s. 6d. per gall. 40% O.P. Dull market.
Wood Tar .. .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead .. £42 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 8½d. per lb. Some business passing at lower prices.
Crude 60's .. .. 1s. 10d.—2s. per gall. Little business passing, but more inquiry.
Acid Cresylic, 97/99 .. 2s.—2s. 3d. per gall. Steady business.
Pale 95% .. .. 1s. 10d.—2s. 2d. per gall. Good demand.
Dark .. .. .. 1s. 11d. per gall. Steady business.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 9d.—10d. per gall. Very quiet.
Unstrained .. .. 8½d.—9d. per gall.
Benzole—
Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.
Standard Motor .. .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 8d.—1s. 10d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 11½d. per gall. Few inquiries.
Middle Oil .. .. }
Heavy .. .. .. } 8½d.—9½d. per gall. according to grade and district. Market very firm. Demand good.
Standard Specification }
Naphtha—
Solvent 90/160 .. 1s. 1d.—1s. 2d. per gall. } fair
Solvent 90/190 .. 1s. 1d.—1s. 3d. per gall. } business.
Naphthalene Crude—
Drained Creosote Salts £7 10s.—£8 per ton. Demand maintained.
Whizzed or hot pressed £10—£14 per ton. Price nominal. No business.
Naphthalene—
Crystals .. .. £18 per ton.
Flaked .. .. .. £18 per ton.
Pitch, medium soft .. 57s. 6d.—60s. per ton. Market weak. Few sellers.
Pyridine—90/140 .. 14s. 6d.—15s. per gallon. Fewer inquiries.
Heavy .. .. 11s.—12s. Steady with fair business.

INTERMEDIATES AND DYES

Business in dyestuffs has improved appreciably with orders being given for larger quantities. Prices are unchanged.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 6d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 6d. per lb. Better demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 8½d. per lb. naked at works.
Aniline Salts .. .. 9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 29/31° C. .. 5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Market quiet.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Market quiet.
Dichloraniline .. .. 2s. 2d. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 3d. per lb. d/d.
Monochlorbenzol .. £63 per ton.
β-Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. .. 1s. 5d. per lb. d/d.
β-Naphthylamine .. .. 4s. per lb. d/d.
m-Nitraniline .. [illegible]

p-Nitraniline ..	.. 2s. 5d. per lb. d/d.
Nitrobenzene ..	.. 5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 11¾d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	.. 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s. 6d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 6d. per lb. 100% basis d/d.
R. Salt	.. 3s. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 7d. per lb. 100% basis d/d.
o-Toluidine ..	.. 7d.—8d. per lb.
p-Toluidine ..	.. 3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine	.. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £52 per ton.
Acid, Acetyl Salicylic	.. 3s. 6d.—3s. 9d. per lb. Steady demand.
Acid, Benzoic ..	.. Commercial acid dearer at 2s. 9d. per lb. B.P. quality remains unobtainable.
Acid, Boric B.P.	.. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 18s.—20s. per lb.
Acid, Citric ..	.. 1s. 5½d. per lb., less 5% for ton lots. Market firm.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Steady market.
Acid, Pyrogallic, Cryst.	.. 6s. per lb., for 28 lb. lots.
Acid, Salicylic ..	.. 2s. 4d.—2s. 7d. per lb. For ton lots 2s. 3d. is quoted. Market slightly easier.
Acid, Tannic ..	.. 3s. 3d. per lb. for B.P. quality.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%. Very firm. Considerable inquiry and buying.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 3s. per lb. Weak.
Amidopyrin ..	.. 14s. per lb. Demand negligible.
Ammon. Benzoate	.. 4s. per lb.
Ammon. Carbonate B.P.	£35 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make. Market neglected.
Barbitone	.. 17s. per lb.
Benzonaphthol ..	.. 5s. 9d.—6s. 3d. per lb. Supplies scarce.
Bismuth Salts ..	.. A steady market. Prices according to quantity :
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
„ Citrate ..	.. 11s. 4d.—13s. 4d. „
„ Salicylate	.. 10s. 2d.—12s. 2d. „
„ Subnitrate	.. 10s. 9d.—12s. 9d. „
Borax B.P. ..	.. Crystal £20, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium ..	.. 9d.—10d. } Steady market.
Sodium ..	.. 9½d.—10d. } Steady market.
Ammonium ..	.. 11d.—1s. } Steady market.
Calcium Lactate	.. 2s. 9d. per lb. for best English make. Market firm.
Chloral Hydrate	.. 3s. 9d. per lb. Weak.
Chloroform	.. 2s. per lb. for cwt. lots.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Guaiacol Carbonate	.. 13s. per lb. for small stocks available. More inquiry. available. Slightly weaker.
Hexamine ..	.. 3s. 9d.—4s. per lb. for foreign makes.
Homatropine Hydrobromide	.. 30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate— Light Commercial	.. £36 per ton net.
Magnesium Oxide— Light Commercial	.. £72 10s. per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol— A.B.R. recryst. B. P.	56s. per lb.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials ..	.. Prices reduced. Market quiet.
Red oxide ..	.. 4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	.. 3s.—3s. 1d. „
White precip. ..	.. 4s. 1d.—4s. 2d. „
Calomel ..	.. 3s. 5d.—3s. 6d. „
Methyl Acetanilide	.. 20s. per lb.
Methyl Salicylate	.. 2s. 10d.—2s. 11d. per lb. for carboys.
Methyl Sulphonal	.. 22s. per lb.
Methylene di-tannin	.. 7s. 6d. per lb. In good demand.
Paraformaldehyde	.. 3s. 6d. per lb., without much inquiry.
Paraldehyde ..	.. 1s. 8d. per lb.
Phenacetin ..	.. 7s. 3d. per lb. Dull.
Phenazone ..	.. 8s. per lb. Dull.
Penolphthalein ..	.. 8s. per lb.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 88s.—90s. per cwt., less 2½%. Firm market. Inquiry good.
Potass. Citrate ..	.. 1s. 8d.—2s. per lb.
Potass. Ferricyanide	.. 3s. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	.. 7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	.. 9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 6s. 3d. per lb.
Salol	.. 3s. 9d. per lb.
Silver proteinate	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 3s. 3d. per lb.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity.
Sod. Hyposulphite— Photographic ..	.. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 87s. 6d. per cwt. Market quiet.
Sod. Salicylate ..	.. Powder 2s. 10d.—3s. 1d. per lb., Crystal at 2s. 11d.—3s. 2d. per lb.
Sod. Sulphide— Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	.. 18s. 6d. per lb.
Tartar Emetic ..	.. 1s. 4d. per lb.

Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed. Distinctly firmer.	

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	13s. 6d. "	
Amyl Acetate	3s. "	
Amyl Butyrate	7s. 3d. "	
Amyl Salicylate	3s. 6d. "	
Anethol (M.P. 21/22° C.)	3s. 9d. "	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. "	
Benzyl Alcohol free from Chlorin	3s. 3d. "	
Benzaldehyde free from Chlorine	3s. 3d. "	
Benzyl Benzoate	3s. 9d. "	
Cinnamic Aldehyde Natural	18s. 6d. "	Cheaper.
Coumarin	21s. "	
Citronellol	19s. "	
Citral	10s. "	
Ethyl Cinnamate ..	10s. "	
Ethyl Phthalate	3s. 9d. "	
Eugenol	11s. "	
Geraniol (Palmarosa) ..	37s. 6d. "	
Geraniol	10s.—17s. 6d. per lb.	
Heliotropine	8s. 6d. per lb.	
Iso Eugenol	15s. 9d. "	
Linalol ex Bois de Rose ..	20s. "	
Linalyl Acetate	20s. "	
Methyl Anthranilate ..	8s. 6d. "	
Methyl Benzoate ..	6s. "	
Musk Ambrette	52s. 6d. "	
Musk Xylol	19s. "	
Nerolin	4s. "	
Phenyl Ethyl Acetate ..	10s. "	
Phenyl Ethyl Alcohol ..	16s. "	
Rhodinol	65s. "	
Safrol	1s. 10d. "	
Terpineol	2s. 6d. "	
Vanillin	26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Aniseo Oil	1s. 11d. "	
Bergamot Oil	14s. 6d. "	
Bourbon Geranium Oil ..	32s. 6d. "	
Camphor Oil	75s. per cwt.	
Cananga Oil, Java ..	9s. 4½d. per lb.	
Cinnamon Oil, Leaf ..	5½d. per oz.	
Cassia Oil, 80/85% ..	9s. 6d. per lb.	
Citronella Oil— Java 85/90%	4s. 7½d. "	
Ceylon	3s. 6d. "	Cheaper.
Clove Oil	9s. "	
Eucalyptus Oil 70/75% ..	2s. 4½d. per lb.	
Lavender Oil— French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil	3s. "	
Lemongrass Oil ..	2¾d. per oz.	
Orange Oil, Sweet ..	12s. 6d. per lb.	
Otto of Rose Oil— Bulgarian	34s. per oz.	
Anatolian	26s. per oz.	
Palma Rosa Oil	20s. per lb.	Cheaper.
Peppermint Oil— English	70s. per lb.	
Wayne County ..	16s. 6d. per lb.	
Japanese	13s. 9d. per lb.	Advanced.
Pettigrain Oil	9s. 6d. per lb.	

TRADE NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

Argentina: Tinplate (167); *Belgium*: Chemical products, ores (147); *Brazil*: Artificial silk (169); *British India*: Silk yarns (139); *Bulgaria*: Small tools, grindstones (12,355/F.E./E.C./2); *Danzig*: Oils (148); *Denmark*: Tinplate, steel, iron (149); *Egypt*: Steel (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W. 1, Ref. E.S.R. 49-3/2); *Esthonia*: Chemicals, rubber, leather (150); *Italy*: Leather (151); *Morocco*: Hardware (160); *Poland*: Leather (8566/F.R./M.C./2); *Rumania*: Petroleum (154); *Spain*: Paper, chemical fertilisers (155); *Sweden*: Paint, chemicals, petrol, oil (157); *United States*: Tiles, cement, coal-tar products (163), tinplate (164), silk (166); *Uruguay*: Tinplate (167); *West Africa*: Iron (162).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during January has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 441, of which 377 were from merchants or importers. To these should be added 17 cases outstanding on January 1, making a total for the month of 458. These were dealt with as follows:—Granted, 363 (of which 340 were dealt with within 7 days of receipt); Referred to British makers of similar products, 52 (of which 41 were dealt with within 7 days of receipt); Referred to Reparation Supplies available, 8 (all dealt with within two days of receipt); Outstanding on January 31, 1924, 35 (mostly dealt with at Meeting of the Committee, held February 1).

Of the total of 458 applications received, 389 or 85 per cent., were dealt with within 7 days of receipt.

Foreign Company News

The Franco-Belgium Syndicate for the Advance of Franco-Belgium interests in the Russian Petroleum Industry, in agreement with the Committee Interallée des Sociétés Naphtifères, has decided that it is impossible to continue to collaborate with the Groupement International des Sociétés Naphtifères.

A new company, the Société Anversoise de Soie Artificielle, has been formed at Antwerp (Belgium) to exploit the viscose process.

The Société Girod Cogne has been formed to take over the electrical steel works at Aosta, where special steels are made.

The Société Industrielle de Coke, Charbons et Agglomérés has been established at Paris to produce special foundry coke by distilling Durham coking coal mixed with English anthracite, and to recover by-products.

The Société Progil (Gillet) has taken over the Société des Anciens Etablissements Cognat, which manufactures wood-distillation products at its works at St. Rambert d'Albon.

The Syndicat Français d'Études Pétrolifères constituted under the Government auspices to form a Union Nationale des Pétroles is negotiating with the Turkish Petroleum Co., and with American petroleum experts, who are studying the oil-fields in Mesopotamia. The negotiations are sufficiently far advanced to enable the Board of Directors of the Syndicat to decide to form the company, which should constitute the national petroleum group, and to ask the French Government to renounce the option which it holds on one-quarter of the shares of the Turkish Petroleum Company.

Trade Information

Dyestuffs Catalogues used to be fascinating productions in pre-war days, but have long been either lacking or uncommon. It is a pleasure to note the appearance of a new series of productions, issued by the Clayton Aniline Co., Ltd., of Clayton, Manchester, to illustrate the effects that can be obtained with the various dyestuffs supplied by that company. Each booklet contains an introduction describing the properties of, and methods of using, the particular dyes, and illustrates the effects obtained by a series of samples, showing a wide and pleasing range of shades. Mention may be made of the booklets devoted to "Direct Colours on Cotton Piece," "Acid Colours on Woollen Piece," "Acid Colours on Woollen Felt," "Chrome Colours on Woollen Piece" and "Union Colours," the last-named being applied by the one-bath process. Of special interest is the booklet devoted to direct and sulphur colours showing "Celanese" effects, a discovery which has placed a new weapon in the hands of the textile designer. Attention may be drawn to a pamphlet, also issued by the Clayton Aniline Co., which details the latest recipes for producing a red upon cotton by means of paranitraniline red, a dye whose brilliancy and fastness combined with cheapness make it a serious competitor of alizarine for many classes of work. A further catalogue is devoted to the direct colours of the Society of Chemical Industry in Basle, colours which are obtainable in this country from the Clayton Aniline Co., Ltd.

British Chemical Standards

The Organisers of the British Chemical Standards movement announce the publication of the complete certificates of analyses of the following samples :—

	Carbon Steel "C."	Carbon Steel "P."	Cast Iron "D."
Carbon	0·091%	0·205%	
Sulphur	—	0·073%	
Phosphorus ..	—	0·105%	
Manganese ..	0·50% (approx.)	0·706%	
Phosphorus [illegible]			1·19%

The samples were first issued about eight months ago, but it has not been possible to publish the full details of all the figures until now. Each of the steel standards has been tested by a selection of about a dozen prominent chemists, representing independent analysts (metallurgical), the U.S. Bureau of Standards, and English, French, Italian and United States iron and steel works chemists (both makers and users).

A special feature of steel "P" certificate is that it contains full notes of the methods actually used by the co-operating analysts.

The standard samples may be obtained in 50, 100, and 500 gramme bottles, either direct from Organising Headquarters, 3, Wilson Street, Middlesbrough, or through any of the leading laboratory furnishers at a price just sufficient to cover the cost. The usual certificate, giving the names of the analysts, the types of methods used, and a detailed list of the results will be supplied with each bottle.

The full list of all the standards now available may be obtained on request.

The Cambridge University Press will shortly publish for the Cambridge Philosophical Society a translation, in two parts, of Dr. Niels Bohr's papers "On the Application of the Quantum Theory to Atomic Structure." Part I., which will appear immediately, is entitled "The Fundamental Postulates of the Quantum Theory," and will be closely followed by Part II., "The Theory of Series Spectra." Dr. Niels Bohr's new work is closely allied to his previous book, "The Theory of Spectra and Atomic Constitution," also published by the Cambridge University Press, the first impression of which is now almost exhausted.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, FEBRUARY 22, 1924 No. 8

EDITORIAL

OUR recent remarks comparing the multiplicity of societies and journals in the chemical, as compared with those in the legal, profession appear to have struck a sympathetic chord in the hearts of many chemists. Unfortunately, chemistry has not yet reached the stage of being a closed profession like the law and medicine, and there is no sharp line of demarcation between the qualified and unqualified practitioner. This fact is probably at the root of a good deal of the deplorable lack of organisation at the present time, and it is difficult to suggest an effective remedy. The closer co-operation now existing between the Chemical Society, the Society of Chemical Industry, and several other bodies is all to the good, but it seems to us that the time has now come for still closer co-operation, particularly on the financial side. At present many chemists spend too large a proportion of their precarious and slender incomes in subscriptions to several societies which maintain certain services in common to which membership of a single society confers the full right of use, for example the excellent library service of the Chemical Society. Surely the time has now come when members of several societies should be able to pay a composition subscription rather less than the total of the subscriptions payable to each individual society? It may be argued that the loss of revenue would be too great, but on the other hand there is the probable large increase of membership. Many of us hesitate to join fresh societies and add to our burdens, and to these of our number a composition subscription might be a strong inducement to join another society whose activities we would like to support if this could be done without too much financial strain. It would be of interest if some such arrangement could be made between the Chemical Society and the Society of Chemical Industry to start with, and if successful it could then be extended to other societies such as the Faraday Society, the Institute of Chemistry, the Society of Public Analysts, etc.

* * *

Although the multiplicity of societies and the many journals to be read are undoubted evils, it is difficult to see how they can be avoided or mitigated in view of the ever increasing specialisation of our science and its applications. One bad effect of this specialisation is seen in the growing use of a hideous jargon of uncouth technical terms. The chemistry of colloids offers possibly the worst examples of this, but no branch of pure or applied chemistry is immune from them. No one can quarrel with the use of special terms when they are necessary for clear and exact understanding, but too often they are coined with a wanton disregard for the difficulties they may cause to workers in other branches of the science. It is not only the scientific writer who sins in this respect. The trade terms used in the different branches of chemical technology are often obscure and sometimes actually misleading to those not intimately acquainted with them. There must be many of our readers who at times are mystified and possibly misled by phrases such as "Marc Oil," "Benzolo, Crude 65's," "Caustic Soda 76/77," "Solvent Naphtha 90/190." Indeed, we recently met with an instance of quite a wrong interpretation of the last named phrase on the part of a person actually engaged in the solvent industry. Perhaps some reader will one day furnish us with a list of these mystifying trade terms, together with their actual meaning. Many of these are of considerable antiquity, and no doubt owe their origin, like many trade terms and many of our more obscure weights and measures, to a desire to keep the knowledge of a particular trade within a charmed circle of the elect. Fortunately in chemical industry we are not called upon to use so bewildering a variety of weights and measures as is usual in some industries, and it is unlikely that the chemist will now be asked to express the results of an analysis in grains per kilderkin.

* * *

The Bureau of Chemical Abstracts is quietly and steadily considering the huge problem which confronts it. The chairman, Professor J. C. Philip, is devoting a good deal of time to the task and he and the other members of the Bureau are already making progress. This small piece of co-operation between two Chemical Societies is destined to become important. We suppose that only those who have taken part in the organisation of joint effort know how slow is the progress that can be made. Among some ten thousand chemists who may be supposed to be affected by the reforms contemplated, a few score are keenly enthusiastic, a proportion is invariably hostile and the great mass is either indifferent or inarticulate. There is no need why chemists should be inarticulate; we

welcome correspondence in our columns and do not hesitate to print any letters likely to interest our readers, whether we agree with the contents or not. We should value highly any contributions from readers who can offer any suggestions for the furtherance of the objects we and they have in view. All our readers will be pleased with the effort made to co-ordinate chemical abstracts. Other forms of chemical publication are receiving consideration, and one of the most notable of these is the book now being prepared in connexion with the British Empire Exhibition at Wembley.

* * *

Chemical science, both pure and applied, will be well represented at Wembley, and will be a striking testimony to the efficiency of British chemistry at the present time. But some more permanent record is required, and the book designed for this purpose will be excellent. It will be called "Chemistry in the XX Century," and is being edited by Dr. E. F. Armstrong, F.R.S., who has found time to organise the preparation of it in addition to his industrial, presidential, and other activities. He himself contributes the Introduction. Sir William Bragg will write on "X-ray Analysis"; and who can do it better? Professor Andrade deals with the "Structure of the Atom"; he has already written on this subject most skilfully. Professor Lapworth has written the chapter on "Valency Theories," a subject with which he is familiar. Sir Henry Miers and Mr. T. V. Barker will deal with "Crystallography," and what they do not know of the subject is immaterial. Dr. Irvine Masson contributes a chapter on "General Physical Chemistry," Professor Baly one on "Spectroscopy," Dr. Hilditch one on "Catalysis," and Dr. Clayton one on "Colloids." Rare Gases, Alloys, Organic Chemistry, Coal-Tar and other Colours, Biochemistry, Explosives and indeed all branches of the science are dealt with by experts whose competence is at once obvious. In a subsequent issue we shall furnish a complete list of these articles and the book is awaited with impatience. It is to be published by our enterprising friends, Messrs. Benn Brothers, Limited. In addition to this book, which is intended for all sorts and conditions of chemists, including those whose knowledge is vague and elusive, there is to be a series of pamphlets intended for a far wider public. These are to make plain to the average man the place occupied by chemistry in the various industries, in our national and daily life, in our homes and in every department of human activity. The organisation of these pamphlets is entrusted to an editor, a poor, harmless drudge, who informs us that his name may with advantage be withheld. By means of this book and these pamphlets it is hoped to make some impression on the public, and it is no small feat to have secured the co-operation of the various authors, busy as they already are with their academic tasks, and their work on the various bureaus, councils and associations. Lack of space has compelled us to omit a long list of contributors to the book of equal eminence to those we have mentioned. This omission will be duly rectified.

THE TRANSPORT, STORAGE AND DISTRIBUTION OF HYDROCHLORIC ACID, WITH AN ACCOUNT OF A COMPLETE MODERN INSTALLATION*

By D. M. NEWITT, A.R.C.S., B.Sc.

The number of industries which now use hydrochloric acid in large quantities has rendered improvements necessary upon the present means of handling and storing it; and since such improvements involve problems of practical importance met with continually in all processes, it is hoped that a survey of the subject will be of general interest.

Amongst industrial chemicals, hydrochloric acid is the most difficult to store in bulk owing to its corrosive action on all materials of which large receptacles can be constructed. The number and nature of the materials used in the manufacture of acid reaction-vessels and acid pumps, together with the lack of any uniform practice in handling the acid afford sufficient evidence of the demand for improved methods.

In considering possible lines of development it is essential to bear in mind the special circumstances arising from the chemical properties of the acid and the very limited choice of material available to withstand its action.

Of those substances inert to hydrochloric acid, nearly all are brittle, and all of them are costly and by reason of their mechanical properties unsuitable for the construction of large sized vessels.

Where the ideal cannot be attained it is necessary to compromise, and, in this case, two alternatives present themselves. Containers of small capacity can be made of an inert material, protected from rough handling by some suitable form of "armouring," or large iron, steel, or wood tanks can be lined with an inert substance.

Both these methods are found in practice, and both are open to criticism on account of the unsatisfactory mechanical properties of the substance which has to resist the action of the acid.

But the former method has objections, in addition, of a more serious nature. The small container is usually made to serve the triple purpose of transporting, storing and distributing the acid.

Its size is therefore limited to such as will provide a one man load, whilst its shape has to be modified to meet the requirements of its manufacture, and results in a vessel occupying a large space in proportion to its capacity.

The glass carboy in this country and its counterpart the earthenware bottle used largely on the Continent, are standard examples of such vessels. The carboy is usually protected by an iron basket packed with straw; together with its packing it weighs nearly forty pounds empty and has a capacity of some twelve gallons.

The economic aspect of handling a commodity used in tons in receptacles holding one hundredweight scarcely calls for comment. Freight charges,

* Read at the meeting of the Institution of Chemical Engineers held on Friday, Feby. 18th.

breakages with consequent loss of acid, and the frequent handling necessary add considerably to the cost of the acid. With so little to recommend it, the wide use of the carboy to-day is one of the anomalies of chemical industry.

Efforts have not been wanting on the part of acid manufacturers to introduce a system of bulk handling of hydrochloric acid, and in some cases they have taken the first step in adopting tank wagon transport; but such a move calls for co-operation on the part of the consumer. The essential concomitant of transport in bulk is storage in bulk. That portion of the acid price which in fact pays for the hire of carboys should be invested in bulk storage; and such an investment may be shown, happily, to be sound.

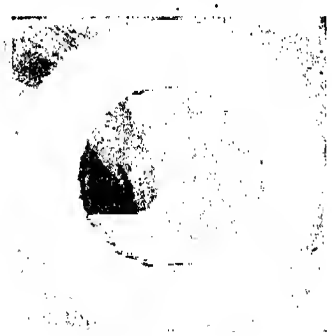

Fig. 1

The introduction of this system involves the provision of a storage tank with distributing mains, pumps and cocks so that the acid may be carried from the tank to the various reaction vessels without any handling.

The Storage Tank

In the selection of material and the design of the storage tank the conditions of its employment differentiating it from an ordinary storage tank must not be overlooked.

Considering a lined iron or steel tank for example, it is essential to have a non-porous lining, made from a material which can derive support by being firmly attached to the metal with as few joints as possible. In this connexion the large coefficient of expansion of iron with rise of temperature is an important factor; for, if, as is usually the case, this coefficient is much greater than the corresponding coefficient for the lining, severe stresses will be set up in the latter with a consequent tendency for the lining to warp away from its support and in extreme cases to crack.

This indeed was the fate of many of the earlier ebonite lined steel tanks, and even with improvements in the quality of the ebonite and the methods of attaching it, such tanks are still somewhat fragile for this reason.

Mention may be made of an attempt to remedy this defect carried out by Messrs. E. I. Du Pont des Nemours and Co.[1] A steel tank was lined with ebonite superimposed upon soft rubber, the rubber being vulcanised to the steel. After several months service the tank was opened up and examined. Several joints in the ebonite lining were found to have given way, but the soft rubber was intact and had completely protected the steel from corrosion.

It will be obvious that the consequences of a break in the lining of a steel or iron tank are serious, for unless discovered early and promptly attended to irreparable damage may be done to the metal plates.

It is therefore best to avoid the use of these metals if possible. The alternative as a material for large tank construction is wood. Certain varieties of wood, such as yellow pine and cypress, withstand the action of hydrochloric acid remarkably well[2], and may be used unprotected in tanks to contain dilute acid. For general use, however, the surface of the wood should be protected from direct contact with the acid, although the demands on the lining are less exiguous than is the case with a metal tank. For instance such a material as asphalt, which is slightly porous and would be inadmissable in the case of iron, forms quite an efficient lining for wood.

Many designs of wood tank for acids have been patented and a number of composition linings recommended.[3] In one case a tank is constructed of two layers of wood with the enclosed space filled with a fused mixture of sand, pyrites and sulphur.

But the material best adapted for the purpose of a lining is an acid-proof quality of soft rubber, and rubber lined tanks, although rarely seen in this country, are largely used in America and have earned a high reputation. It is evident that, given acid-resistant properties, rubber is a material peculiarly suited to the service. Its strength and resistance minimise the danger of damage through accidental rough usage, and when used in conjunction with wood a tear in the lining may be repaired both quickly and without risk of damage to the tank.

The special feature of the installation described below is then the use of a soft grey rubber mixture, as a lining for wood in the case of the storage and reaction tanks, and in the form of hose for the pipe lines.

This rubber has a specific gravity of 0·98 and a breaking stress of 2000 lbs. per sq. inch. A sample, tested by immersion in boiling hydrochloric acid (38 per cent.) for 48 hours, remained unchanged. As far as can be seen it is inert to sulphuric acid up to a strength of 70 per cent., acetic acid to 10 per cent., ferrous chloride to 50 per cent., and to any strength of oxalic acid, phosphoric acid and sodium chloride.

It is not suitable for use in the presence of free halogens.

The effect of heat on the rubber is influenced by the nature of the liquid in contact with it. In some cases a temperature of 130° C. may be safely used and in most cases a temperature in the neighbourhood of 100° C. causes no ill effects. This may be contrasted with the behaviour of ebonite which softens rapidly when heated above 70° C.

As a practical example of the behaviour of this rubber in contact with Hydrochloric Acid, Fig. 1

will be of interest. This illustration is from a photograph of a section of rubber hose that has been used continuously for twenty years for the conveyance of strong acid. An examination of the section shows that the inner surface of the rubber has shrunk slightly and has become somewhat harder for a depth of $\frac{1}{16}''$, but no other change is apparent.

In addition to the advantages of strength and durability accompanying the use of rubber and wood, the cost of an installation built up of these materials is very much less than that of any other combination that can be employed for the purpose.

The plant described here is for the storage of twenty tons of Hydrochloric Acid of Sp. Gr. 1·2, and its distribution to eight acid baths in two groups. Its object is to replace four hundred carboys hitherto used both for the storage and the distribution of the acid.

Since all the baths are on ground level, gravity is made use of for distribution, and to give sufficient head the storage tank is mounted on a wooden foundation four feet high. This provides an average fall of 0·9 inch per foot for the 120 foot main.

The choice of shape for the storage tank lies between rectangular and round with nearly all the advantages in favour of the latter. A round tank in addition to being easier to make and erect, has all its iron supports on the outside and visible, whilst the rubber lining can be applied with only a quarter of the number of seams demanded by a rectangular construction.

Fig. 3 is taken from a photograph of the tank in position. It is ten feet in diameter and ten feet high and slightly tapered from bottom to top. The wood used is 3″ yellow pine, the staves being supported by twelve $\frac{3}{4}''$ W.I. hoops bent to the circle of the

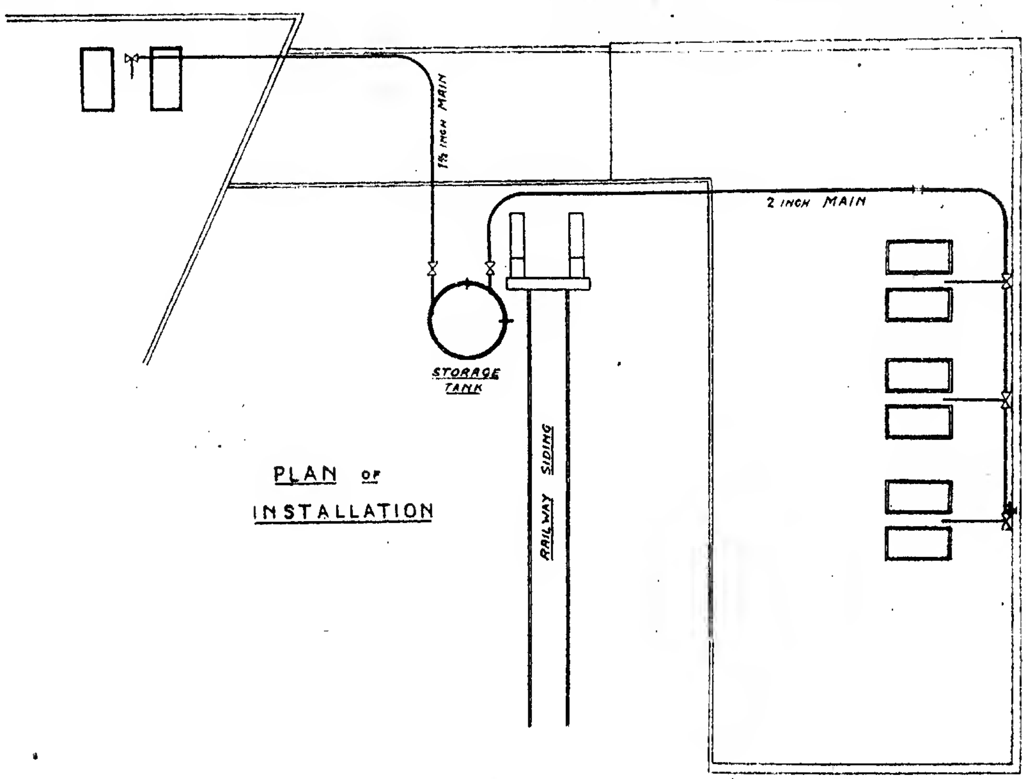

FIG. 2

Fig. 2 shows in plan the situation of the acid baths relative to the goods yard where the acid enters the works.

It will be observed that the storage tank has been placed close to a railway siding to facilitate rapid and direct filling from a tank wagon. Two acid mains are then necessary for distribution; one of length 60 feet to feed two baths, and the other of length 120 feet for the remaining six baths in the long shed.

tank and fastened by adjustable lugs. The lugs (Fig. 4) are so designed as to fit close to the staves, and to prevent the ends of the hoops being forced into the sides.

An octagonal cover to the tank protects its contents from the weather, and stops the escape of fumes.

Both the outside of the tank and the iron hoops and lugs are painted with coal tar pitch.

The lining consists of sheets of acid proof grey rubber mixture, $\frac{3}{32}''$ thick. To obtain perfect

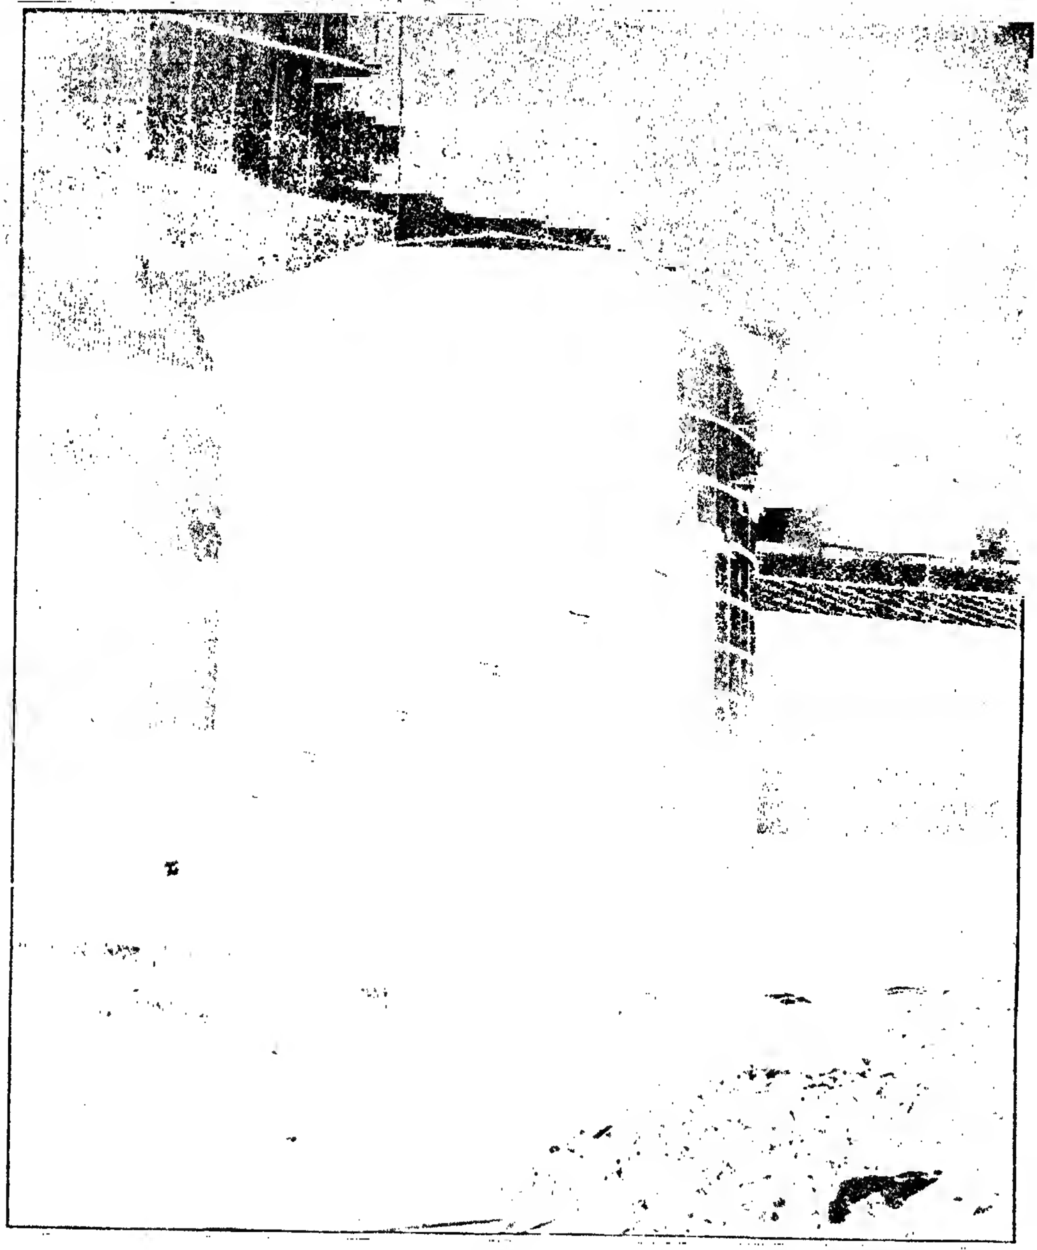

Fig 3

adhesion with the wood the inside of the tank must be free from ridges or other irregularities.

A backing composed of strong rubber impregnated fabric is first applied. The sheets of rubber, after having been vulcanised, are then rolled on to this fabric, and pressure and heat maintained until adhesion is complete. The seams in the lining are covered with broad rubber straps and sharp bends are avoided.

There are no breaks in the lining for exit pipes, distribution being effected by syphons.

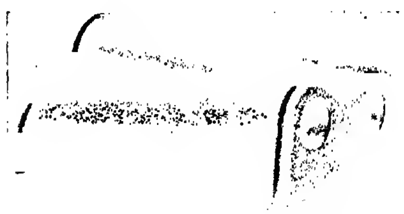
The Distributing System

Second in importance to the storage tank are the acid mains; and here again practice differs as to the choice of material for the pipes.

Ebonite, silica, glass, earthenware boiled in tar, and soft rubber have all been used. As in the case

of tanks, the nature of these materials render it necessary to protect the pipes either by a suitable casing or by running the line as far as possible out of reach of accidental blows, a condition not always practicable. With the exception of the last, they are rigid and brittle, and can only be obtained in short lengths. Ebonite pipes, for instance, are not made in lengths much exceeding ten feet; a main 60 feet long would thus have seven joints, and all joints are potential leak points.

Soft rubber piping, on the other hand, is made in lengths of 65 feet and therefore very few joints are necessary, and the risk of leaks in the mains is minimised. In addition, pipes of this material may be carried round bends and corners which would require special sections in the case of rigid pipes.



MALLEABLE IRON LUG FOR ROUND HOOPS

FIG. 4

The two mains used in the installation described here are made of acid proof hose, and are supported along their whole length in wooden launders to which they are fastened by loose straps at intervals of 15 feet.

The shorter one, 1½″ in diameter, feeds the two isolated baths, and the other, 2″ in diameter, feeds the battery of six baths. The mains are supplied by rubber syphon tubes, the bend of the tubes being carried over the edge of the storage tank on wooden shoulders to avoid strain and deformation.

The positions of the cocks are indicated in Fig. 2. Hard rubber cocks have been found most suitable for this purpose; but in special cases they may be advantageously replaced by bronze pinch cocks, of a design similar to those used in chemical laboratories.

Attention is called to the safety cocks placed as near the storage tank as possible in each main. The mains are in general carried close to the walls of buildings out of harm's way; the reaction vessels are then fed by short lengths of hose branching from the mains.

In each long length of pipe about one foot of overlength has been allowed. The slack is taken up in bays close to the ends of the pipe and provides for remaking a joint without disturbing the main pipe.

RELAY TANKS AND REACTION VESSELS

From the mains the acid is delivered to relay tanks or direct to the reaction vessels. Both must be made of or lined with acid resisting material.

The relay tank may be of similar design to the storage tank. A very convenient form is shown in section in Fig. 5. The purpose of this tank is to permit of the acid from the mains being diluted, heated or otherwise treated before being run into the reaction vessels.

Since all chemical reactions involve energy changes, the reaction vessels have to withstand, in addition to the acid, more or less rapid fluctuations of temperature. It may also be necessary to carry out the reaction under reduced or high pressure.

This introduces new factors into the design of the tanks. The effect of heat on the material used to line the tank must be ascertained. Ebonite and asphalt for example soften and become plastic above a certain temperature, whilst stone and ceramic materials are liable to crack as the result of sudden changes in temperature or pressure.

Moreover the mechanical wear on the lining may be considerable, due to the abrasive action of suspended solids in an agitated liquid, or to the formation of a precipitate or sediment which has to be dug out from the bottom of the tank.

For reaction vessels therefore a much stouter construction is both necessary and desirable.

Without venturing on a comparison of the various types of vessels in use, a comparison rendered difficult by the multiplicity of processes in which hydro-

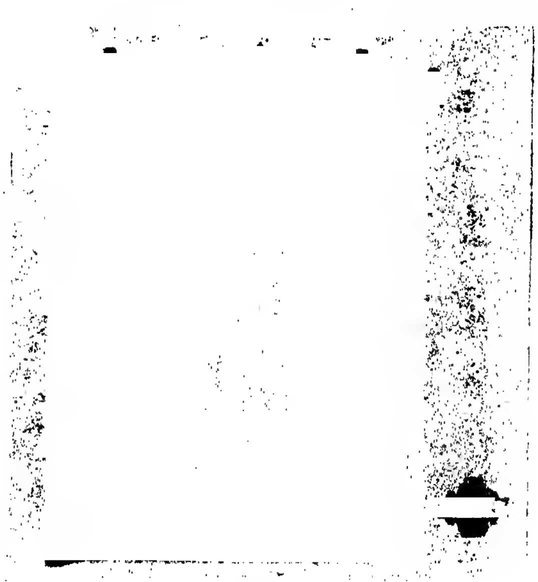


FIG. 5

chloric acid is employed, a brief description will be given of the application of lined wooden vessels to two typical reactions; these will be found to offer guidance in the majority of cases that arise.

In the first type of reaction, a crystalline product was obtained by adding solid in small quantities at a time to a 10 per cent. solution of hydrochloric acid, heated to 65° C. by steam, and kept constantly

agitated both during the addition of the solid and during the subsequent cooling and crystallisation.

A rectangular rubber lined tank was specified. The tank was ten feet long, four feet wide and three feet high and made of 3" cypress. After being in use some months it was observed that whilst the main structure of the tank was adequately protected by the rubber lining, the lining itself showed signs of wear, due to the scouring action of the crystals. It would, of course, be possible to repair or renew the lining from time to time as occasion required; but it was found to be cheaper and better to protect the rubber from mechanical action by a light inner lining of wood. This could be renewed at small cost when worn out. Such a lining need not be tight since its only function is to act as a buffer between the rapidly moving particles and the rubber surface.

Fig. 6 shows, in plan and elevation, the tank fitted with its double lining. The rubber lining is carried well over the edges of the tank to protect the vertical rods from acid and the outside of the tank is given a coat of pitch.

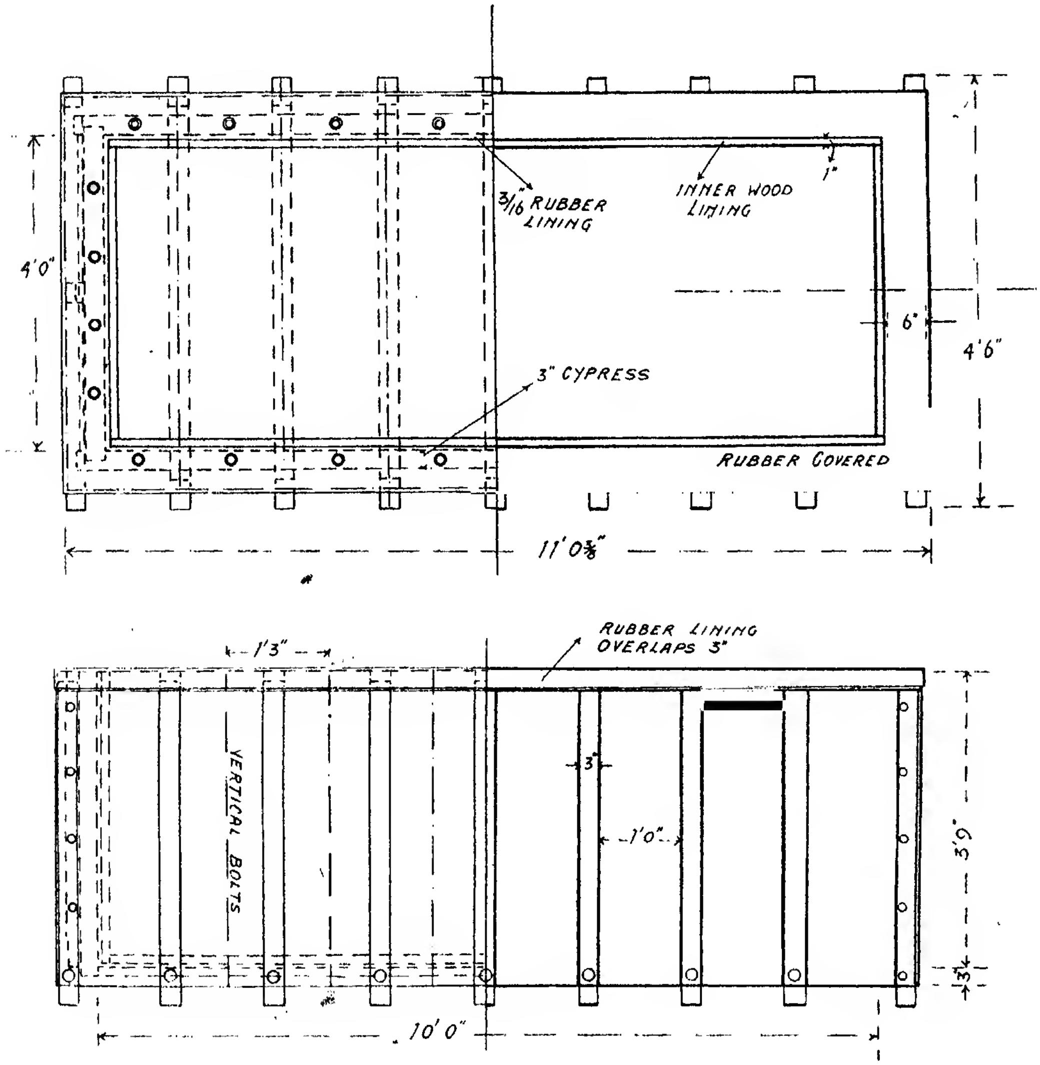

Fig. 6

In the second type of reaction the chemical change is initiated, or accelerated, by reduced or high pressure, and by heat.

Closed vessels must be used, and in order to provide the necessary strength a cylindrical construction is always adopted. It is also very essential to have perfect adhesion between the lining and the wood.

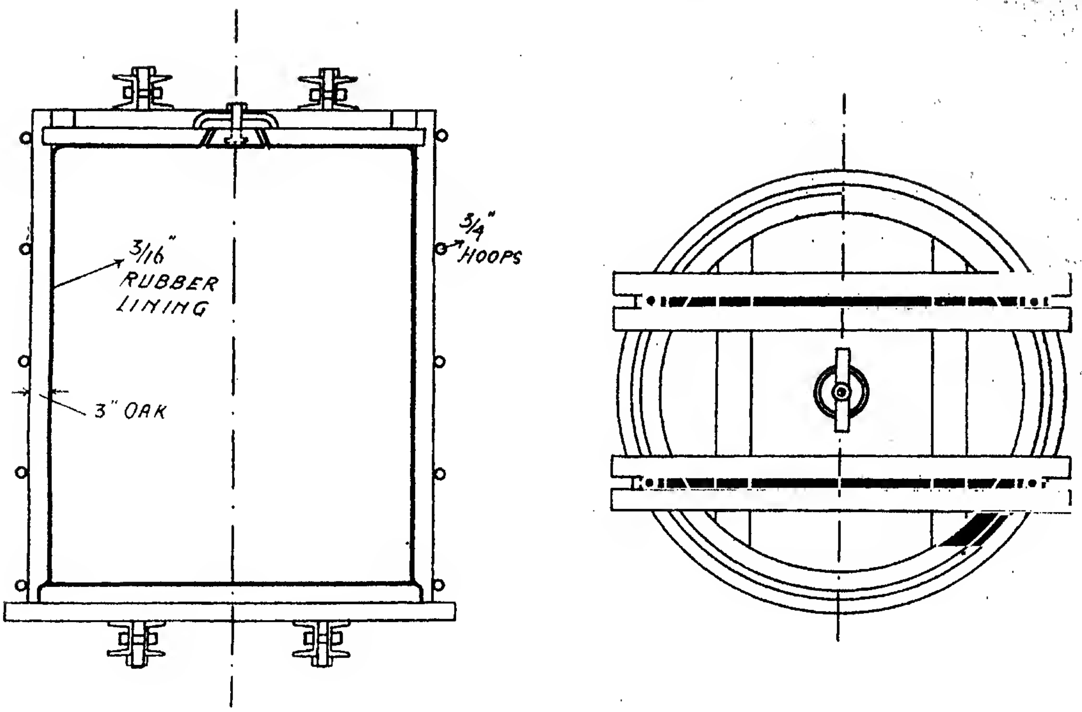

FIG. 7

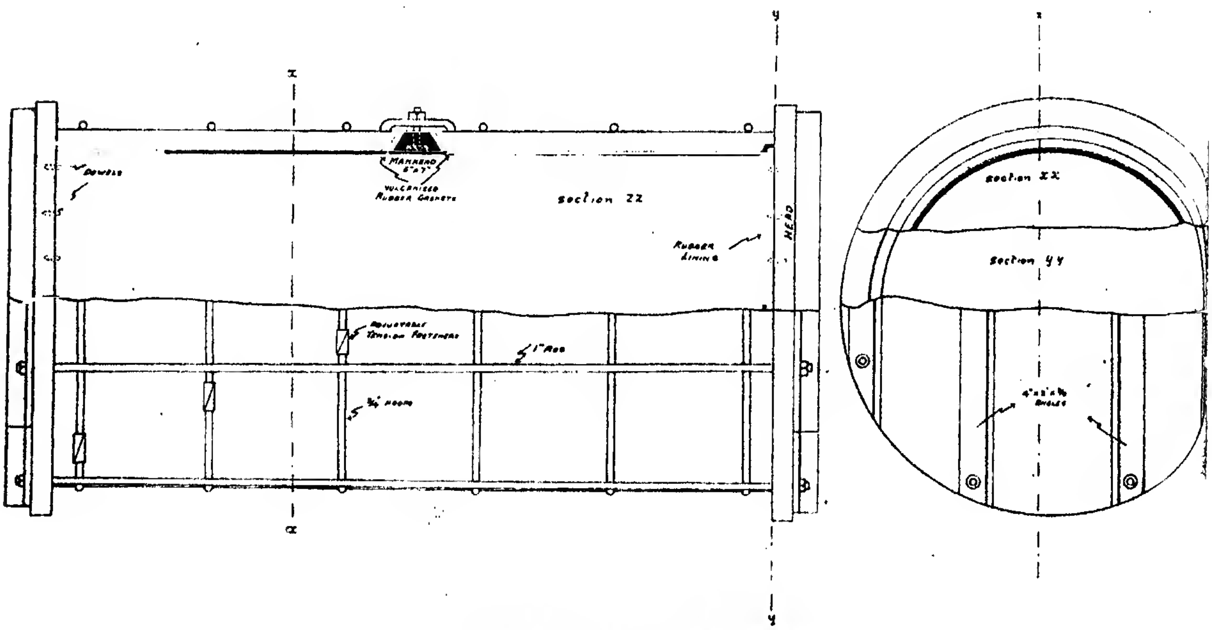

HYDROCHLORIC ACID WAGON TANK

FIG. 8

Fig. 7 illustrates a form of tank designed to hold 10 lbs. pressure. It is made of 3" oak, lined with rubber. The staves are bound by five, $\frac{3}{4}$" W.I. hoops, and the ends are held in position by two pairs of channel girders connected by iron rods. To permit of lining, repairing and cleaning this tank it is necessary to have a detachable end as shown in the section. The opposite end may then be crozed into the staves, and provided with the necessary exit pipes, pressure gauges, etc.

Other examples of the application of a rubber and wood construction to process vessels will suggest themselves.

Transport

The transport in bulk is a separate and important phase of the handling of acid[4].

A wagon tank is called upon to encounter the mischances of travel by road and rail. It must length of the tank. The lining is a special acid proof rubber $\frac{1}{16}$" thick. The double ends give additional strength and render cleaning and internal repairs easy to carry out. The outside of the tank is coated with coal tar pitch.

The tank is mounted on wooden cradles and strapped in position by wire ropes.

Fig. 9 illustrates the mounting of a 10 ton tank on a standard 15 ton wood underframe of regulation size.

A point often overlooked in the design of wagon tanks is the provision of adequate devices for rapid filling and emptying. The selection of suitable fittings will depend on the power available for pumping the acid at the various works where it has to be delivered. When compressed air of sufficient pressure is available it may be used connected direct to the

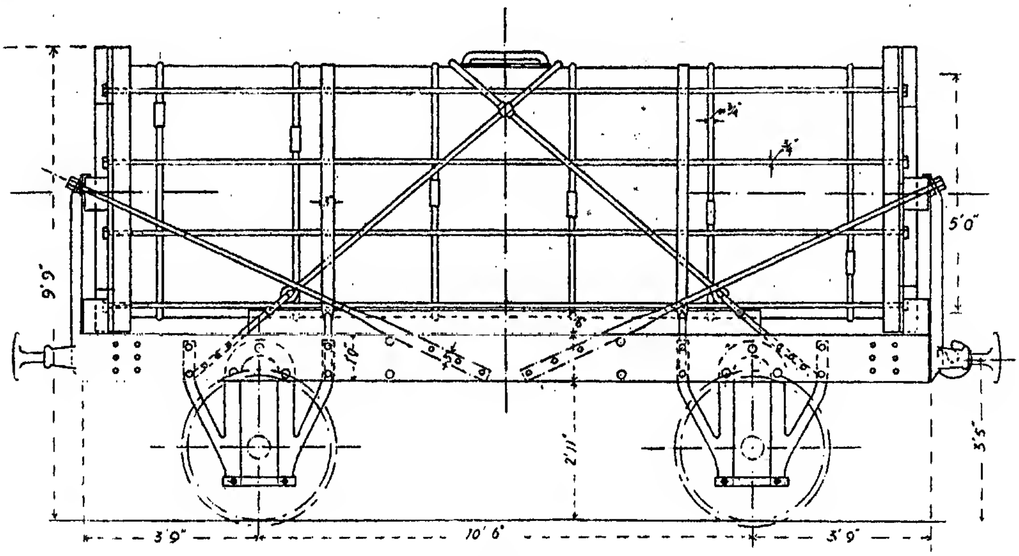

Fig. 9

be so designed as to withstand continual vibration and shocks, and in the event of a collision to remain intact. It has also to stand the internal pressures used in blowing the acid from the wagon to the storage tank, which may be situated a considerable height above ground level. Provision has to be made in the design for rapid cleaning and repair.

The dimensions of such a tank are, in the case of rail transport, governed by the railway companies' regulations for private owners tank wagons, and in the case of road transport by the carrying capacity of the vehicle employed.

Fig. 8 shows in elevation a rubber lined wood wagon tank designed for road transport. It has a capacity of 600 gallons. It is constructed of yellow pine and is cylindrical in shape and double ended. The staves are supported by $\frac{3}{4}$" W.I. hoops and the ends are clamped together by four angles 4" × 3" × $\frac{3}{8}$" connected by $\frac{3}{4}$" bars running the whole wagon tank, or through the medium of an acid elevator of the automatic type. Alternatively a centrifugal pump may be more convenient. Much unnecessary delay and expense will be avoided by an agreement on the question of plant and fittings between the manufacturer and the consumer.

Costs

The chemical and engineering aspects of handling hydrochloric acid in bulk have been considered, but the duties of the chemical engineer do not terminate at this point.

When introducing a new system involving capital outlay, it is necessary to show an adequate return for the expenditure; and this is often a matter of some difficulty. It is seldom possible to express in terms of money the value of time and labour saving resulting from some more efficient method of carrying out a process.

In the present case, however, some definite figures are available which throw an interesting light on the nature of the investment.

It has been seen that there are three methods of handling hydrochloric acid.

Method I. By transporting, storing and distributing in carboys.

Method II. By transporting in wagon tanks, and storing and distributing in carboys.

Method III. By transporting in wagon tanks, storing in bulk, and distributing through pipes.

In Table I the items of expenditure associated with the three methods of handling the acid are enumerated.

An example has been taken where the acid is purchased, weekly, in ten ton lots, and is delivered to a factory, situated 100 miles on a direct route from the acid works.

TABLE 1

	£	s.	d.
Method I. Acid purchased in carboys and stored and distributed in carboys.			
Carriage on carboys in 10 ton lots at £1 1s. per ton	£10	10	0
Carriage on returned empties at 12/6 per ton ..	£1	19	0
Cost of unloading full carboys and loading empties (estimated)	£1	15	0
Distribution of acid (estimated)	£0	10	0
Breakage (at 1%)	£1	14	0
Interest on investment in carboys at 5% ..	£0	3	3
	£16	11	3
Investment by consumer . . . nil			
" by manufacturer . . . 400 carboys at 8/6 each	£170	0	0
Method II. Acid purchased in tank wagon and stored and distributed in carboy.			
Carriage on acid in tank wagon at 18/- per ton including return of tank	£9	0	0
Cost of unloading into carboys (estimated) ..	£1	0	0
Distribution of acid (estimated)		10	0
Breakages (at 1/2%)		8	6
Interest on carboy investment (at 5%) ..		1	8
Interest on tank wagon investment (at 5%) ..		3	10
	£11	4	0
Investment by consumer . . . 200 carboys at 8/6 each	£85	0	0
" " manufacturer . . . 1 rubber lined wood wagon tank	£200	0	0
Method III. Acid purchased in tank wagon and stored in bulk and distributed in pipes.			
Carriage on acid in tank wagon at 18/- per ton (including return of tank)	£9	0	0
Interest on tank wagon investment (at 5%) ..		3	10
Interest on storage tank and distributing system (at 5%)		2	4
Renewals and repairs (at 5%)		2	4
	£9	8	6
Less rebate on price of acid at 5%	£2	0	0
	£7	8	6
Investment by consumer . . . Storage tank and distributing system	£120	0	0
" " by manufactorer . . . 1, rubber lined tank wagon	£200	0	0

In Method I thé consumer, in addition to paying for the acid, has to pay carriage on the full carboys, the cost of unloading and reloading empties and the carriage on the returned empties.

Included in the price of the acid is the allowance for breakages, estimated at 1 per cent., renewal of packing and hampers, and the interest on the capital invested in carboys.

A charge of 10s. for distribution, estimated, has also been allowed.

In Method II the cost of handling and freight charges are reduced. The allowance for breakages no longer appears in the price of the acid, but still exists and must be added to the costs. It is now estimated at ½ per cent. since the carboys require less handling.

The cost of unloading is reduced somewhat, but distribution remains the same.

Interest on the investment in carboys must be allowed, and interest and costs of repairs and renewals to the wagon tank will appear in the price of the acid.

In Method III the freight charges are the same as in Method II. The items of cost of unloading, breakages and distribution disappear. (A small charge should be allowed for unloading, but this is difficult to estimate).

Additional items are the interest on the investment in storage tank and distributing system, and the allowance for renewals and repairs.

From the total costs, however, must be deducted a very considerable rebate allowed by the acid manufacturer to consumers purchasing their acid in bulk and storing it by this method.

This may be between 5 per cent. and 10 per cent. of the purchase price. It represents the increase in efficiency that accompanies a bulk method of handling.

If the price of acid is taken at, say, £4 per ton the rebate, calculated on the lower percentage, amounts to £104 per annum, and is sufficient to pay for the cost of the entire installation in less than two years.

An installation, such as the one described, should last for upwards of twenty years. There is, therefore, a big margin available for the reduction of cost of manufacture in processes using hydrochloric acid.

In conclusion it may be said that a method based on uniting the properties of two substances cannot be regarded as entirely satisfactory, but advantage must be taken of the best materials available until the ideal has been discovered. Possibly this will be found among the new alloys of iron; but it is an annoying circumstance that, so far, these alloys appear to become brittle in proportion as their resistance to acid increases; consequently they share some of the disadvantages that are seen to accompany the use of most inert compound substances.

My thanks are due to Messrs. Boulton & Paul, Ltd., of Norwich, for permission to refer to their new installation, and for the photograph (Fig. 3) of the storage tank which was constructed at their works.

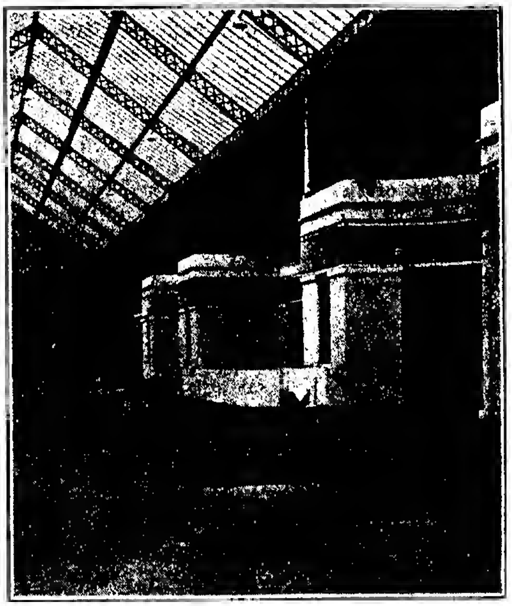
THE BRITISH ASSOCIATION OF CHEMISTS

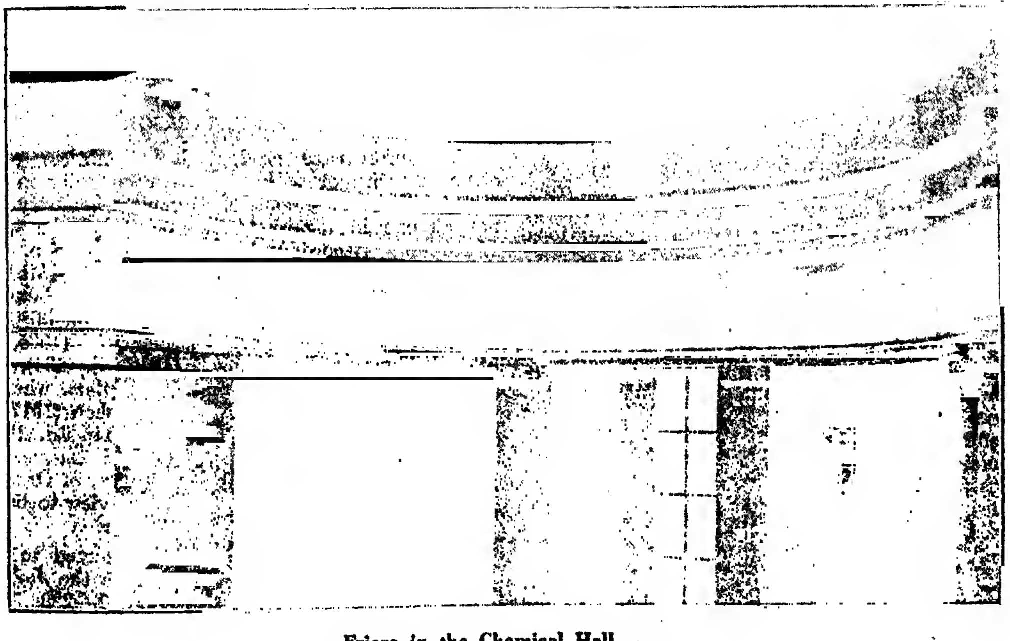
The British Association of Chemists was founded to look after the material welfare of chemists, and it has sections in several parts of the British Isles. In those districts where the chemical industries are active, it seems to have a large membership. There is much work to be done in improving the status and emoluments of chemists and this is the task which the Association has undertaken. Its London section held its third annual dinner on February 16, at the Engineers' Club, Coventry Street. Dr. Herbert Levinstein, the President of the Association took the chair. An excellent musical programme was provided, and the various items were much appreciated by the members present. The chairman proposed the toast of the London section to which Mr. E. R. Redgrove replied. Mr. Price proposed the toast of kindred societies, to which Dr. S. Miall replied. Mr. Cory proposed the toast of the ladies and guests, and to this toast Miss Wright replied. Mr. C. S. Garland proposed the toast of the president, and alluded to the discussions held with the Institute of Chemistry towards some co-operation between the Institute and the Association. Dr. Levinstein, in an interesting speech, made a suitable reply.

AN OBJECT LESSON

Travelling outwards from Baker Street in the gloomy mist of a February morning, one passes after a few minutes' run, a huge sign whose yard-high letters announce the "Site of the Amusement Park." At the same time strange erections in timber appear, out-topped by distant views of stately buildings, minarets and towers. Steam cranes are active, puffs of steam twist away, and men swarm ant-like among structures whose ungainliness little suggests their future fascination. This confusion of buildings, timber structures, and muddy

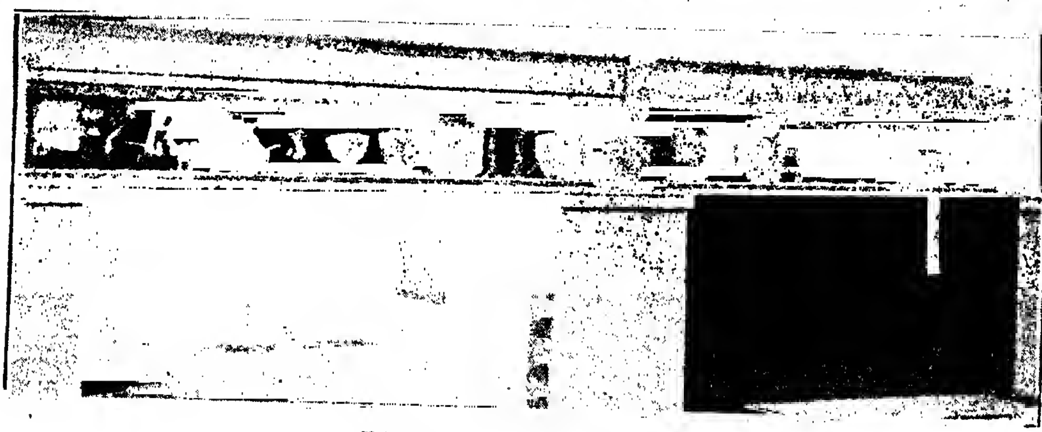


British Empire Exhibition: Part of the Chemical Hall



Frieze in the Chemical Hall

roads will blossom out in a couple of months into the unique attractions of the British Empire Exhibition, an effort of unparalleled magnitude. Governments, Colonies, industries, trades, all will be represented, but the section that will interest the readers of *Chemistry and Industry* most is the Chemical Hall. Passing through the organised muddle of erection one comes to a huge hall, the Palace of Industry, in an ideal position, close to the north entrance near Wembley Park Station. In the Palace of Industry, which covers more acres than one cares to remember, is the Chemical Hall. It will be a source of pride to chemists to know that the largest single exhibit in the Palace of Industry will be that of the Chemical Industry, which will occupy an area of no less than 37,500 sq. ft. But, quite apart from the large area occupied—even the powerful cotton industry occupies no more than 32,187 sq. ft.—the exhibits themselves will be of unusual interest. Already there is a long list of firms which are going to exhibit—there are far too many to mention here—and one can people the Chemical Hall with fascinated throngs gazing at the lovely colours of dyes or of copper sulphate, admiring glistening piles of dry ammonium sulphate or limpid jars of glycerine; or following the representations of chemical life in laboratory or in works, so admirably delineated in the vigorous colours of the frieze by Mr. Cosmo Clark. Drugs, essences, soap, chemicals, fine or heavy, all will be there, and it can safely be prophesied that little will be lacking. This is not all, for there is an exhibit which should drive home to every visitor the fine record of British chemists and chemistry. There will be a complete representation of our present state of knowledge of chemistry, and as the organising committee includes so many eminent exponents of the various branches, the exhibit will be of no small interest. Catalysis, chemical engineering, alkaloids, agricultural chemistry, to mention but a few of the many subjects, will be expounded by specimens, often of great historical interest. If the visitor is interested in explosion waves or terpenes, isotopes or ions, crystals or colloids, he will find something of interest. It is impossible to give an idea, within the covers of this journal, of the vast scope of the scientific exhibit. It is to be hoped that the double, double, double beat of the thundering drum will not be neglected, for such an opportunity to instruct as well as edify is hardly likely to occur again within some generations. The Chemical Hall should be an object-lesson to the many millions of visitors, home and overseas, to teach them at least something of the far-reaching importance of British chemical science and chemical industry. The visitor to the Exhibition sees, first thing, where the Amusement Fair is to be. One feels sure that though the Chemical Section of the Exhibition may not be amusing, it will certainly leave a profound impression on those who see the vast hall decorated, completed and populated.



Frieze in the Chemical Hall

THE DERIVATION OF THE WORD "MERCAPTAN"

By T. S. PATTERSON

The unfortunate student has doubtless often observed, with or without further curiosity in the matter, that text-books of Organic Chemistry are not at one in regard to the origin of the word *Mercaptan*. According to Holleman (1905, p. 78) Bernthsen (Eng. Ed. 1922, p. 91), Walker ("Medical Organic Chemistry," 1913, p. 145), Meyer and Jacobson (1907, **1**, i, 319), Miller ("Elements of Chemistry," 1880, **3**, 661), "Watt's Dictionary" (1865, **2**, 547), "Thorpe's Dictionary" (1912, **3**, 434), the word is derived from *corpus mercurio aptum*, whereas Perkin and Kipping (1904, p. 187), Cohen (1917, p. 195), and Richter (1891, p. 140; German Ed. 1909, p. 160) derive the word from *corpus mercurium captans*. Thomas Thomson ("Chemistry of Organic Bodies," 1838, p. 325), perhaps with a view to being on the safe side, derives it in both ways.

A few years ago attention was directed to the matter in a paper by Paul Diergart in the *Journal für praktische Chemie*, 1919, [ii], **99**, 281—292. The paper, itself perhaps not conspicuous for clarity, is dismissed in the Chemical Society's Abstracts with

the single, almost contemptuous word, "historical," and since the English reader is not much assisted thereby to a judgment upon the subject it is perhaps worth while to explain briefly the true inwardness of the matter.

In 1824 Wilhelm Christopher Zeise (1789—1847), Professor of Chemistry in the University of Copenhagen, examined the action of carbon bisulphide on ammonia, etc., and discovered thereby the xanthates, which, it appeared, might be regarded as carbonates in which some of the oxygen had been replaced by sulphur. This led to other experiments, and by distilling calcium ethyl sulphate with barium hydrosulphide the liquid which is known as mercaptan was obtained—in, or shortly before, the year 1833. The earliest intimation of this discovery was a note in Schweigger-Seidel's *Journal für Chemie und Physik** 1833, **8**, 146, a full account of the work being presented to the Kongelige Danske Videnskabernes Selskab. This account was first issued, in 1834, in the form of a reprint, two years before the appearance of the volume in which it was ultimately published. Copies of this reprint were sent by Zeise to several Journals, and translations or abstracts appeared in at least four. The original reprint had probably very little circulation and is now scarcely or not at all procurable. Even the *Afhandlinger* of the Danish Society after their appearance in 1836, would also not be very easily accessible and Zeise's work therefore became known through the translations or extracts, which were published almost simultaneously.

A preliminary note appeared in the *Journal für praktische Chemie*, 1834, **1**, 186, and in the same volume, pp. 257—268, 345—356, 396—413, 457—475 a full translation was given. As a result of his work Zeise arrived at the constitution $C^4H^{12}S^2$ for mercaptan, and $C^4H^{10}S^2Hg$ for that of the mercury compound. The passage is as follows :—" In accordance with the idea that the metal in this compound, as in the sulphocyanides, forms one member, and $C^4H^{10}S^2$ the other, and that in consequence the ethereal body is $C^4H^{10}S^2+H^2$, I name the substance taken up by mercury *mercaptum*, (*i.e.*, *corpus mercurio captum*) and the other *hydro-mercaptum*, or rather (partly to avoid connecting the nomenclature with an idea still hypothetical, partly for brevity), *mercaptan* (*i.e.*, *corpus mercurium captans*), the final *s* being dropped for euphony.

"This nomenclature may seem offensive to some but hardly more than the names chloral, picamar, oxamid, etc., etc., and those who are acquainted with the present position of our notions of the compositions of the substances in question will surely grant that such, if I may so call them, innocent names, are, temporarily at least, preferable to those which suggest an opinion as to the actual nature of the compound. . . . Against the name mercaptan it might, amongst others, be objected that it is really the *mercaptum* that is seized by the mercury ; but this seems to me to be of little importance." (Pp. 265, 266.)

A different translation of the paper appeared in Poggendorff's *Annalen*, 1834, **31**, 369—431. In this translation (p. 378) *mercaptan* is derived as before from *corpus mercurium captans*, but *mercaptum* is derived differently from *corpus murcurio aptum*, *murcurio* being an obvious misprint, whilst the fact that there is a considerable space between the *o* of *murcurio* and the *a* of *aptum*, might give rise to the idea that the letter *c* had dropped out by chance, the derivation of *mercaptum* from *corpus mercurio captum* having just as much to recommend it as the derivation from *corpus mercurio aptum*. It is a least clear from this that Zeise distinguishes between the substance which we now call *mercaptan*, and its radical $C^4H^{10}S^2$, for which he proposed the name *mercaptum*.

Berzelius—to whom a copy of this reprint was most probably sent—gave an account of Zeise's work in his *Jahresbericht* (1835, **14**, 334) which was presented to the Swedish Academy of Sciences on March 31, 1834. He mentioned that "Zeise names the assumed saltformer $C^4H^{10}S^2$ *mercaptum* (from *mercurio aptum*, because it has a great affinity for mercury) ; but instead of calling its compound with hydrogen *mercaptum*-hydride he calls it *mercaptan* (from *mercurium captans*), dropping the final *s* for the sake of euphony—or, rather, not to drive the dissonnance too far." To this Berzelius added a footnote :—" It becomes constantly more necessary for chemists to harden their ears. Daily a number of new ternary compounds are discovered, for which so far no rational system of nomenclature is possible and for which names are invented from Latin or Greek derived from one or other property of the compound without the slightest regard for euphony. In the course of the past year alone science has been enriched with the following ear-splitting names : Peucil, Peucedanin, Pittakal, Mercaptum, Mercaptan, Thialöl, etc. It is very desirable that those who make discoveries in science should not heap it up with cacophonies." Berzelius added :—" *mercaptum* has not yet been isolated as such but only in combination with metals or hydrogen."

Also in a letter to Wöhler of March 28, 1834, Berzelius wrote :—" A no less curious discovery is Zeise's sulphur mess*, which he has named mercaptan (from *mercurium captans* ! ! !) dealing with it in a paper of seventy-two pages which one reads with much the feelings one would have if driving through sand on a sledge. But the thing itself is excellent." It seems clear from the reference to the length of the paper as well as from the date, that Berzelius must have had the original reprint in his hands, and not one of the translations.

A short abstract of Zeise's paper also appeared in Liebig's *Annalen*, 1834, **11**, 1—10, with an addition pp. 10—14, over the initials J.L., the addition containing, however, mainly other parts of Zeise's paper. In this the derivation of the word is not given but Liebig finished up his note with a remark similar to Berzelius's. "I think I ought to point out to Herr Zeise how much his excellent and masterly investigations lose in interest by diffuseness and the description of experiments which gave no result. The treatment of every chemical compound

*Forerunner of the Journal für praktische Chemie.

*" Schwefelschmiere " applied to a liquid or to a piece of work is a little difficult to translate.

in the same manner would exhaust even the greatest patience." (pp. 13, 14).

Another extract appeared in the *Annales de Chimie et de Physique*, 1834, [2], 56, 87—96, and here *mercaptum* is given as from *corpus mercurio aptum* (p. 93) and *mercaptan* as from *corpus mercurium captans* (p. 88).

The original paper ultimately appeared in 1836 in the first part of Volume VI of the *Naturvidenskabelige og mathematiske afhandlinger der kongelige Danske videnskabernes Selskabs*, the volume however bearing on its title page the date 1837. In the paper (p. 13), *mercaptum* is derived from *corpus mercurio aptum* and *mercaptan* from *corpus mercurium captans*. It is clear therefore that Zeise intended *mercaptum* —derived from *mercurio aptum*—to be name the of the *radical* C^2H^5S, and *mercaptan*—derived from *mercurium captans*—to be that of the *substance* C^2H^5SH.

It is a little difficult to understand why the confusion in the text-books should have arisen at all. That information about mercaptan was originally disseminated by means of the translations has nothing to do with the matter, since in all the translations the derivation of *mercaptan* is correctly given. In the version given in *Journal für praktische Chemie*. the name of the radical mercaptum is incorrectly derived from *mercurio captum* instead of *mercurio aptum*, but this, if anything, should have had the opposite effect to that produced. The fact is, perhaps, that even authors of text-books of Organic Chemistry may nod occasionally, and fail to consult the original sources. In any case it is clear that Zeise, whose right to dictatorship in the matter is inalienable, intended the word *mercaptan* to be derived from *mercurium captans*, and that most of the text-books are wrong on this point.

Organic Chemistry Department,
University of Glasgow

INSTITUTION OF THE RUBBER INDUSTRY

At the meeting held in London on February 4, Mr. F. Kaye, who introduced the process for making rubber-latex paper, described a new use for rubber latex in the manufacture of boards, leather and linoleum substitutes. The amount of latex required in making boards, etc., varied from 30 to 40 per cent. of rubber content (more than is used in making rubber latex paper), the quantity depending on the nature of the fibre and the purpose and quality of the final product. The increase in tensile strength was greater with low-grade materials than with stronger fibres. The development of the manufacture of latex boards should lead to a big range of new products made by paper-making and board machines, *e.g.*, floor-cloth, leather boards, asbestos boards, mill boards and containers. Latex boards are easy to colour and could be used in the electrical industry. As latex boards are well suited for embossed effects, they could find use in book-binding, panelling, etc. The boards can be self-vulcanised during manufacture at very small cost.

Feb. 27. Royal Microscopical Society, 20, Hanover Square, W. 1, at 7 p.m. "Practical Microscopy in Research on Textile Fibres," by H. J. Denham.

Feb. 28. Institution of Electrical Engineers, Savoy Place, W.C. 2, at 6 p.m. "The Design of Apparatus for the Protection of Alternating Current Circuits," by A. S. FitzGerald.

The Physical Society of London is arranging to celebrate its jubilee from March 20 to 22 next. The preliminary programme of the proceedings will be as follows: On Thursday, March 20, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2. at 2.30 p.m., there will be an Exhibition of Apparatus, followed by a reception at 3.0 p.m., and at 3.45 the Guthrie Lecture on "Photo-electric Effects in the case of High Frequency and Allied Phenomena" will be delivered by M. le Duc de Broglie. On Friday, March 21, from 4.0 to 5.30 p.m., and from 6.0 to 7.30 p.m., reminiscences by Original Fellows and other Fellows of long standing will be given, and on Saturday, March 22, there will be a continuation of the Exhibition, and at 7.0 p.m. for 7.30 a banquet will be held for Fellows and guests only.

The Council of the Physical Society extends to the members of this Society a hearty invitation to be present at these meetings, and, according to present arrangements, no tickets will be required for this purpose.

SOCIETY OF CHEMICAL INDUSTRY

LIST OF MEMBERS ELECTED,

February 8, 1924

Armstrong, Dr. W. G., Public Health Department, Sydney, N.S.W., Australia. Director-General.

Baird, David, 25, Princes Place, Ardrossan. Student.

Brown, Harold B., Chemical Dept., Rowntree and Co., Ltd., The Cocoa Works, York. Technical Chemist.

Carmichael, Kenneth F., 2, Kirkton Road, Burntisland, Fifeshire. Chemist.

Coates, William M., 28, Admiral Street, Burnley. Assistant Chemist.

Davidson, Wilmot A., Chemist in Charge, Department of Health, Vancouver, B.C., Canada. Dominion Analyst.

Douglas, Mark, 27, Mosley Street, Newcastle-on-Tyne. Analytical Chemist.

Ewing, Charles W., c/o Canadian Woollen Manufacturing Association, 256, McCaul Street, Toronto, Canada. Research Chemist.

Fawcett, Thos. C., Northern Sabulite Explosive Co., Ltd., Tuthill Quarry, Haswell, Sunderland. Engineer.

Gordon, Andrew R., 40, Heath Street W., Toronto, Canada. Assistant.

Gould, Thos. L., 116, Chestergate, Stockport. Manufacturing Chemist.

Lewis, William L., 11, Clifton Wood Road, Clifton, Bristol. Manager.

McGrath, Thomas, c/o The Condensed Milk Co. of Ireland, Lansdowne, Limerick, Ireland. Biological Chemist.

Martyn, George, Latchley, Sandymount Drive, Wallasey.

Murray, Alexander F., 3, Burns Park, Ayr. Works Chemist.

Muspratt, Horace, 15, Alexandra Drive, Sefton Park, Liverpool. Director.

Price, Edward E., The Haven, Dorman's Park, Surrey. Chartered Accountant.

Rhodes, J. E. Wynfield, Gorphwysfa, 1, Deyne Avenue, Prestwich, Manchester. Lecturer.

Thompson, Rudolph E., 596, Milverton Boulevard, Toronto, Canada. Chemist.

Tweedale, Albert E., 26, King Street South, Rochdale. Chemist.

Wright, Carl J., Combustion Utilities Corporation, 8-10, Bridge Street, New York, N.Y., U.S.A. Chief Technologist.

DEATH

Moulsdale, William E. (elected 1917), of 6, Castle Street, Liverpool, Metallurgical Engineer. On January 20, 1924.

ANNUAL GENERAL MEETING, 1924

The Annual General Meeting of the Society of Chemical Industry will be held in Liverpool on Wednesday, July 9. Members are asked kindly to note this preliminary announcement. Further particulars will be published in due course.

INSTITUTE OF CHEMISTRY

LONDON & SOUTH-EASTERN COUNTIES

A special general meeting of the London Section was held on January 23 in the Meeting Hall of the Institution of Mechanical Engineers. All Fellows and Associates of the Institute in the London area were invited to attend.

The Chairman, Mr. E. R. Bolton, in introducing Mr. W. J. U. Woolcock, C.B.E., reminded the members of the discussion which the Section held early in 1923 on the subject of the organisation of chemistry, with special reference to the possibility of greater co-operation.

Mr. Woolcock said that as a looker-on he was possibly able to see some things which chemists might miss. In the published synopsis of his address he had said that there was a need for a serious effort to unite the profession of chemistry by fusing or assimilating the various bodies concerned with the advancement of the profession and the science. He felt that members would take this point for granted, but he would emphasise three points.

First, they could not claim that the public were yet educated as to the functions of the chemist. They could not even invite prominent men of affairs to dine with them without laying themselves open to listen to speeches which clearly indicated that their guest was confusing their profession with the calling of pharmacy. Then, again, he was not satisfied that everything possible had been done to bring the whole body of those who practised chemistry as a profession into one professional organisation. The Institute had on its flank another body which was claiming to do some of the work which a professional organisation might undertake. Finally, scientists, and particularly chemists, had shown a peculiar aptitude for waste. They had specialised in wasteful and uneconomic methods. They had split themselves up into a multitude of small societies, and had, further, taken great care that the headquarters of all those societies should be as far apart as possible, and that, when it was necessary to select officers for any of them, the officers should have had as little contact with the work of the other societies as possible.

He then referred to the Federal Council. In 1918, when the Federal Council was formed, chemistry was in a relatively prosperous condition, and it was comparatively easy for the small body of enthusiasts who had formed this Council to prepare the ground for a larger scheme of co-operation. Nobody could claim now that chemistry or any other profession was flourishing, and the time was at hand when the members were pressing for that more lively action which they could expect from a council containing their own elected representative members. The more intimate fusion of British chemical bodies was especially desirable now, seeing that they all had to contend with financial difficulties. It was not now possible for chemists to keep in touch with all the societies to which they were attracted. He would not like to say exactly how many societies connected with chemistry there were in the United Kingdom —probably only Mr. Pilcher would be able to tell

them—but they were all doing useful work in one sphere or another, and it was clear that the present cost of membership of all of them would be prohibitive. He had suggested that the bodies involved in the proposed amalgamation should be the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, and all other societies interested in the advancement of the science and its application. All these societies should be linked up at first in a loose manner, so that the advantages of membership of all of them should be available to members of all the other societies at a much less cost than was now possible.

During the last few years the relations between chemists and industrialists had improved wonderfully, but there was still room for great improvement, and therefore he suggested that the associations of British chemical manufacturers (there was more than one association), whilst obviously they could not be constituent societies (since membership of such associations was not individual), should be affiliated to the proposed amalgamated body. He wished to do all he could to bring chemists and industrialists into close contact one with another.

He had already to some extent referred to the objects of the amalgamation. The first he would suggest would be economy in organisation. The societies should co-operate by the election of a General Chemical Council, containing the nucleus of the Federal Council, and elected representatives from each of the bodies, which would manage the affairs of the new body. They would appoint committees corresponding with the councils of the present individual groups or societies respectively, who would carry on the work and maintain the traditions of those groups or societies. Further, they would appoint a joint secretariat. If the latter point were not capable of immediate realisation, great good would inevitably accrue if the secretariats of all the bodies were housed in the same building.

The second object of amalgamation was to secure economy in publication and printing. Something had already been done in this way, and he need not elaborate upon the fact that more economies could be effected.

Thirdly, they would effect the provision of a joint library, which was an extension of the present scheme for the use by other bodies of the library of the Chemical Society.

He referred to the scheme which had been put forward by the Federal Council for the inauguration of Chemistry House. Unfortunately, immediately after this proposal had been made, the present trade depression had set in, and the time was not yet ripe to ask for large sums of money. The ideal was a fine one, and would go a long way towards co-ordinating the interests of all the bodies which had their headquarters at Chemistry House. They must continue to work for this ideal, but they must face the practical fact that the ideal would be difficult of immediate accomplishment in the present circumstances. They would be wise to proceed with plans for federating the interests of the various bodies associated with chemistry without necessarily awaiting the completion of their building; particularly should they aim at joining together those bodies whose interests were more nearly associated. The other similar bodies would join them readily when this was accomplished.

Mr. E. V. Evans said that it was a great pleasure to him to see that the members of the Institute were taking serious thought of the need of co-operation between the various chemical bodies. He reminded the meeting of the steps which had already been taken, first of all in the formation of a joint Library, and, secondly, in the formation of a joint Bureau of Chemical Abstracts, with Prof. Philip as chairman. He hoped that these steps were but an indication of the more complete collaboration which would eventually be brought about. He was spending annually about £30 in subscriptions to various chemical or allied societies, and he spent nearly £50 a year more in getting supplied with technical literature. He agreed, therefore, that any steps which could be taken to relieve this burden upon chemists would be welcome to the members. In this connexion, he had been pleased with the formation of the Chemical Engineering Group, by which it had been found possible to prevent the formation of yet another distinct chemical body, and the Society of Chemical Industry had every reason to be proud of its satelite.

Prof. Philip said that, speaking as one with intimate knowledge of all three of the societies, he did not quite see how the Institute came into such a federation. He could conceive that the Chemical Society and the Society of Chemical Industry, for instance, could usefully co-operate even more than they were already doing or were proposing to do, but if the Institute were to come in there would be immediately a difficulty in that the Institute was mainly a qualifying body. It was possible to belong to either of the other two societies without possessing any serious chemical qualification, provided that a candidate was really interested in chemistry or its applications. The whole subject, was one worthy of every consideration, and he thought that the present efforts in the matter of the Library and publications were an earnest of good things to come.

Mr. E. M. Hawkins had some doubts as to the wisdom of including the Institute in the project; amalgamations were not always a success unless the bodies to be amalgamated had definitely the same aims. He felt that this was the case with the Chemical Society and the Society of Chemical Industry, but was doubtful as to the position of the Institute.

Mr. R. Leslie Collett disagreed entirely with Mr. Hawkins and with Prof. Philip. He maintained that the common ultimate aim, whether of the Institute, or of the Chemical Society, or of the Society of Chemical Industry, was to advance chemistry. This over-ruled any of their immediate objects, whether they were looking after chemists or after the propagation of pure chemical knowledge or of chemical knowledge as applied to the arts and industries. It was true that the immediate functions of the Institute were different from those of the Chemical Society and the Society of Chemical Industry, but that was all the more reason why the

Institute should come in with all its vigour to promote the common aim.

The key to the whole situation, however, was Chemistry House. They were holding this meeting in the hall of the Institution of Mechanical Engineers, because when London members of the Institute or of any other body expected about five per cent. of their members there was not room for them in any chemical building, and they had to seek the hospitality of the Engineers or of some other body who had adequate headquarters. That of itself showed the urgency of the demand for Chemistry House. He did not agree with Mr. Woolcock that the ideal was not immediately obtainable. If they could not immediately get sufficient funds to buy a house, which he doubted (all these bodies had money tied up in capital funds against the rainy day which was with us, but which nobody would believe was wet), they would at least rent a large building and see that all their offices and meeting halls, were in one building. He, therefore, urged that members should set their hearts upon the immediate acquisition of adequate chemical headquarters. It could be bought later when money was forthcoming. Apart altogether from the question of federation, good must necessarily accrue if the officers of the various bodies were housed in the same building. At present the Institute was the only body which had its own building, and nobody could claim that even the Institute was satisfied as to the adequacy of its accommodation. The Chemical Society were notoriously crying out for more space, particularly for the Library. The Society of Chemical Industry was hidden away from the usual place where chemists were to be found, and had no real accommodation. The matter was, therefore, very urgent.

The Registrar of the Institute said that while he was much interested in the idea of federation, he thought that, as Prof. Philip had suggested, it would be found better, in the first place, to federate the bodies which were more closely allied both in their functions and aims.

Mr. C. L. L. Claremont thought that the opener was at fault in discussing the closer organisation of the profession. He was of opinion that the profession was already fully organised by the Institute, and that anybody who was not in the Institute was not in the profession.

Dr. O. L. Brady said that with regard to the Federal Council, the idea was excellent, and it was clearly desirable to have some co-ordinating body. The method on which that idea was worked out, however, was at fault since the net result had been to collect on the Federal Council a number of presidents or other high officials of the constituent societies, all of whom were busy men and unable to give that time to the affairs of the Federal Council which was necessary.

The present Federal Council was in the nature of an advisory council. The council of the new body must have full executive powers if it were to be of any use.

He agreed with Mr. Collett that, though the functions of the various bodies might differ, their ultimate aim was the advancement of chemistry, and the Institute should pull with its proper weight.

Mr. C. E. Sage spoke generally in favour of the proposals. He emphasised that, during the last thirty or forty years, movement had all been in the direction of splitting up chemists into their separate groups, and as each group or society had grown in size and in importance it had engendered the formation of yet other satellites. Latterly the movement had been towards federation, but Mr. Woolcock's proposals would undoubtedly interfere with the liberty of a number of the federating societies. At the same time they must realise that it was most inconvenient to attend a meeting or committee in Bloomsbury, then have dinner at Charing Cross, and go to Piccadilly for another meeting.

Mr. Woolcock was then called upon to reply to the discussion. He made a brief reference to Mr. Claremont's remarks, which he considered very interesting, but as not to be taken seriously by those who realise the progressive position of chemical affairs. It could not yet be claimed, for instance, that membership of the Institute was the sole qualification of a chemist when it was realised that there was more than one prominent professor who was not a Fellow of the Institute. In his opinion, the discussion had brought to light one serious criticism, namely, the position of the Institute in the proposed federation. It had been very properly pointed out that the Institute was in a different category from the other bodies, but he held with Mr. Collett that any body which represented chemists should not be outside the scheme of federation. The proposed federated body would clearly have to make provision for different grades of membership. There would no doubt be a grade corresponding with Fellowship of the Institute and another with Associateship of the Institute. These grades would comprise all who had qualifications entitling them to consideration as members of the Institute. There would have to be another grade, which would comprise those who were interested in a less direct manner in chemistry.

The members of the Institute might possibly not come as readily into the scheme of federation as the members of the other bodies, but, in any case, he thought that the Institute would be doing a great dis-service to chemistry if it held itself violently back.

Dr. Brady then moved:—

> "That this meeting of Fellows and Associates of the Institute of Chemistry of Great Britain and Ireland urges the Council of the Institute to take immediate steps to invite the co-operation of all bodies concerned with the progress of the profession and science of chemistry in order to ascertain the best means for co-ordinating the activities of the various organisations with the ultimate prospect of federation."

The resolution was seconded by Mr. McLachlan. An amendment, moved by Mr. Claremont, to delete the words "the profession and," was not seconded. The resolution was then put to the meeting, and carried unanimously.

The meeting closed with a hearty vote of thanks to Mr. Woolcock

PERSONAL AND OTHER ITEMS

Dr. Alexander Scott, F.R.S., who has completed his work in advising on the preservation of the objects found in the tomb of Tutankhamen, left Egypt on February 10 for England.

From Paris the deaths are announced of Monsieur L. Roman, professor at the Ecole Centrale des Arts et Manufactures de Paris, and of Monsieur J. Bonnardel, president of the Cie Industrielle du Platine and of the Société des Forges et Aciéries de Huta Bankowa.

Dr. T. J. Murray has resigned his post as head of the Chemical and Metallurgical Department of the Wolverhampton Technical School to become Principal of the Smethwick Technical School.

Dr. W. E. Faragher, the author of numerous researches on the chemistry of hydrocarbons, and an authority on petroleum refining, has been appointed an assistant director of the Mellon Institute of Industry Reseatch, University of Pittsburgh.

Dr. I. N. Ivanor, whose death is announced from Berlin, was responsible for the development of numerous factories in Turkestan, including the santonin factory at Tskimkent, non-nationalised by the Soviet Government.

BRITISH INDIA

Final Forecast of the Sesamum Crop, 1923-24

From reports based on a memorandum received from provinces which contain, on an average, 99·6 per cent. of the total area under sesamum, it is estimated that the total yield is 382,000 tons (excluding Hyderabad), as against 425,000 t. of last year. This represents a decrease of 10 per cent. The weather was not very favourable, and the condition of the crop is reported to be, on the whole, fair.—(*Ind. Tr. J., Jan.* 17, 1924.)

RHODESIA

Petroleum and Coal in Rhodesia

As the result of exploration at Inyaminga, 117 miles from Beira, on a concession covering 4200 sq. miles, it is claimed that the presence of coal was proved, and that the geological structure was similar to that of the Persian oilfields. It is suggested that boring at a point near Inyaminga would " in all probability disclose the existence of huge quantities of petroleum."—(*S. Afric. J. Ind., Jan.*, 1924.)

CANADA

Mineral Wealth of Ontario

Up to the end of 1923 the mines of Northern Ontario have produced gold, silver, platinum, nickel and copper worth over $600,000,000. More than 250 million tons of ore and rock has been taken from the nickel-copper mines of the Sudbury district, yielding approximately $255,000,000, and placing in ascertained reserves at least another 100 million tons of ore, with an indicated gross value of two billion dollars. The mines of the Cobalt, South Lorrain and Gowganda district have produced over 340 million ozs. of silver valued at approximately $210,000,000. Dividends from a great many of these silver mines have been exceedingly big—ranging from a few hundred per cent. to as high as 25,000 per cent. on the capital invested. The silver bullion sent out from this few miles square of territory would make up approximately twenty trainloads of about twenty cars to each train.—(*Official.*)

Production in Nova Scotia

During 1923 the products of Nova Scotia yielded in revenue about $168,000,000 including: Coal, $36,410,000; coke and by-products, $3,286,000; gold and other minerals, $255,000; gypsum, limestone, etc., $3,195,200; building materials and clay products, $1,940,500; iron and steel products, $12,620,000; fisheries, $11,779,300; manufactures, ships and freights, $53,185,000; farm products, $26,045,100; forest products, $12,350,600; grand total, $167,846,700.—(*Official.*)

FRANCE

French Imports of Rubber.

During the first eleven months of 1923 French imports of rubber totalled 33,295 metric tons, of which England furnished 15,272 t., British India 7452 t., French Congo 772 t., Indo-China 3179 t., French African Colonies, except Congo, 575 t.

Metallurgy in November

The production of the State coal mines in the Sarre in November, 1923, reached 1,076,587 metric tons, so that the average production per working day was 45,938 t., *i.e.*, 681 kg. per workman per day. The factories attached to the mines produced 14,717 t. of coke, against 16,000 t. in October.

Basic Slag

The consumption of basic slag as a fertiliser is increasing in France. Before the war the import of basic slag averaged 400,000 t., but in 1922 the import was 27,325 t., and the export 308,326 t. In 1923 imports during the first nine months reached 27,270 t. and exports, prohibited since October, reached 197,852 t. on October 1. Imports of basic slag come chiefly from the Sarre region and the exports go to Germany, Belgium, Switzerland and Luxembourg.

The Utilisation of Samba for Paper-Making

Samba (*Triplochiton Scleroxylon*), occurring in Guinea, the Ivory Coast, Dahomey and the Cameroons has been investigated for use in paper-making. The wood contains 60 per cent. of cellulose and 39 per cent. of lignone, but only 33 per cent. of cellulose was obtained in the technical tests, the paper produced being of common type. When bleached, the pulp was a dull white, slightly rough to the touch and fairly supple. Resistance to tearing, rubbing and other tests was mediocre. Very thin sheets can be obtained, the felting power being 0·015. With energetic treatment the lignone is easily eliminated, and the wood seems well suited for paper-making.

Alcohol Production

During the first three months of the season (October, November and December, 1923), the

production of alcohol was 920,793 hectolitros, of which 524,607 hl. was reserved for the State, and 396,186 hl. delivered for sale. Imports amounted to 64,127 hl. The stock in hand on December 31 was 1,158,350 hl. There is a slight excess over the production in 1922-23, but a slight diminution in the stock on hand.

Export Prohibitions

Tho export or re-export of coal, briquettes of lignite, coal or coke is prohibited, save by special permission of tho Ministry of Finance.

GENERAL

Minerals in New Caledonia

The Société le Nickel has just obtained a contract for the delivery of from 600 to 1200 metric tons of nickel ore under advantageous conditions. Exploration for auriferous copper has been less active lately, but a trial shipment of 75 t. has been sent to Newcastle, Australia. As exploration has given such satisfactory results, the company will probably increase its capital.

Radium Production in Czechoslovakia

According to the *Czechoslovak Trade Journal*, roughly 24 g. of radium, or about 12 per cent. of the world's output, was produced at Joachimsthal during the years 1909-22. It is estimated that the total world's production of radium to date is about 204 g. Production in Czechoslovakia in 1920 was 2·2 g. (valued at 22 million kronen), in 1921, 3·2 g. (32 mill. kr.), and in 1922 2·2 g. (11 mill. kr.).—(*Ch. Comm. J., Jan.* 25, 1924.)

Rubber Industry in Japan

In 1923, between 500 and 600 factories in Japan were engaged in manufacturing rubber articles, the most important being rubber toys, the value of which in 1922 was 1,611,982 yen, and which are now being exported in large quantities to Australia, South America, and India. Rubber tyres are also being produced at low prices, and find a market in China and the Dutch Indies. Statistics published in the *Bulletin* of the Tokio Chamber of Commerce show that during 1922 Japanese imports of crude rubber and gutta-percha amounted to 16,581 tons, valued at 11,315,384 yen, as against 23,164 t., valued at 15,742,019 yen, in 1921. To show the growth of the rubber industry in Japan since 1914, it is stated that the total importation in that year of crude rubber and gutta-percha was only 1039 t., valued at 2,146,634 yen. The value of rubber output has grown from 15,028,864 yen in 1917, to 41,635,634 yen in 1921.—(*Ch. Comm. J., Jan.*, 1924.)

Abrasive Materials in 1922

In 1922 natural abrasives were produced in 26 States, the quantities sold being as follows:—Grindstones and pulpstones, 26,524 short tons; oilstones and scythestones, 1016 t.; emery, 1468 t.; garnet, 7054 t.; diatomaceous earth and tripoli, 74,966 t.; pumice, 45,262 t.; grinding pebbles and tube-mill lining, 3159 t. The total value of the sales of natural abrasives was $2,732,674, whereas that of sales of artificial abrasives was $5,317,485, and taking account of imports valued at $1,695,402 and exports worth $1,217,615, the apparent consumption reached the value of $8,527,946. The artificial abrasives, produced to the extent of 103,262,000 lb., were of three kinds, viz., metallic, silicon carbides and aluminium oxides.

Extension of University of Oxford Science Department

It was announced in Convocation on the 19th inst., that the Trustees of the Rockefeller Foundation had offered £75,000 to the University for the development of the Department of Biochemistry, and the University has authorised a large extension of the space allowed in the University Park, for this purpose.

REVIEWS

THE MICRO-ORGANISMS OF THE SOIL. *By* SIR E. JOHN RUSSELL, F.R.S., *and Members of the Biological Staff of the Rothamsted Experimental Station. Pp. viii.+188. London: Longmans, Green & Co.*, 1923. *Price* 7*s*. 6*d*.

Great advance has been made in our knowledge of the micro-organisms of the soil since Pasteur suggested in 1862 that nitrification was probably a biological action, and Schloesing and Müntz produced proof some fifteen years later that this was so. Until the end of last century it was the action of bacteria, and especially of a few classes of bacteria such as those which cause nitrification and denitrification, and those which bring atmospheric nitrogen into organic combination either in symbioses with leguminous plants or otherwise, which attracted most attention, and other classes of micro-organisms were almost neglected. During the past twenty years a great change has been in progress, and the protozoa, the fungi, and the algae of the soil have all become subjects of study, and, though our knowledge of these is still in its infancy, a whole literature concerning them has sprung up and the foundations, at any rate, have been laid of an edifice of exact knowledge concerning them. The older text-books of agricultural science may make some reference to nitrification and fixation of free nitrogen, but the student who wished to know anything of the recent work on tho bacteria, protozoa, algae and fungi of the soil, and the interrelations of these, had practically to dig it laboriously out of the original papers. The time had come for a work which would place this knowledge within the reach of teachers and students of agricultural science.

No place has played a greater part in investigating the micro-organisms of the soil than the Rothamsted Experimental Station. Since the investigation of the partial sterilisation of the soil, started in 1907, led Sir John Russell and Dr. Hutchinson to the fruitful conclusion that the increase in the number of soil bacteria is kept in check by soil protozoa, and that therefore soil fertility depended on the numbers of protozoa as well as on the numbers of bacteria, attention has been turned to soil protozoa, and after these soil algae and fungi also received increased attention. At Rothamsted a staff of

experts has been built up to form a team for the study of all these different soil organisms. This very valuable book has been written by the heads of this staff, and probably there is no other institution which could have produced such a book; certainly there is no other in Britain.

The opening chapter, which is largely historical, deals with the development of the idea of a soil population. This and the closing chapter which gives a summary of the chemical activities of the soil population and their relation to the growing plant, are contributed by Sir John Russell himself. The remaining chapters deal with what is known concerning different classes of soil organisms. Mr. H. G. Thornton writes two chapters on soil bacteria, which he classifies not according to morphological characters, but according to their physiological activities, a method which is much more useful to the soil student. Naturally the special work carried out at Rothamsted in the decomposition of cellulose and the formation of artificial farmyard manure from straw comes in for special attention.

The chapters on Protozoa are contributed by Mr. D. W. Cutler, the head of the Rothamsted Department of Protozoology, whilst Dr. Muriel Bristol contributes a chapter on Soil Algæ and Dr. W. B. Brierley two chapters on Soil Fungi. A chapter on the invertebrate fauna of the soil, other than protozoa, is contributed by Dr. A. D. Imms. Many of these organisms are not micro-organisms, but, very wisely, the picture of the soil population has been completed by their inclusion in the book.

Any student who reads this monograph will have no excuse for cherishing that common student delusion of the certainty and fullness of our knowledge. Each author in turn comments in one way or another on the limitations and uncertainty of the information on the subject with which he is dealing, and points out how much still remains to be investigated. One might almost say that the prevailing note of the whole book is the unsatisfactory state of our knowledge of all the subjects with which it deals. As is natural, the work which has been done at Rothamsted always claims special attention, but other work is not forgotten. At the end of each section an excellent bibliography is given. The work is well and clearly printed, and contains few typographical errors. It can be recommended to all students of agricultural science, and should be in the hands of every agricultural teacher.

JAMES HENDRICK

DIFFERENTIAL EQUATIONS IN APPLIED CHEMISTRY. *By* FRANK LAUREN HITCHCOCK *and* CLARK SHOVE ROBINSON. *Pp. vi*+110. *New York: John Wiley and Sons; London: Chapman and Hall*, 1924. *Price* 7*s*. 7*d*.

This small book is based on a course given to students of chemical engineering at the Massachusetts Institute of Technology, and the practical needs of this type of student are kept in the forefront. Graphical methods are freely used, and perhaps the most useful feature is the inclusion of numerous excellent examples. The answers are not given, and although the authors say that this was deliberate policy, it would probably have been more useful to have given the answers. The main part of the book is taken up by a detailed discussion of such simple types of differential equations as occur in chemical dynamics, and an elementary knowledge of calculus is assumed. The book, therefore, will be a useful supplement to elementary works on the calculus intended for chemical students, and the line of treatment adopted will appeal especially to men studying chemical engineering. Some of the very simple standard types of equations do not seem to be very well known to chemists, and a large amount of space is frequently wasted in journals by the reproduction of detailed calculations leading to results which are well known standard forms, and could have been written down at once by inspection of the primary equation. Perhaps this book may serve as an introduction to some of these forms.

J. R. PARTINGTON

DIRECTORY FOR THE BRITISH GLASS INDUSTRY 1923. *Published by the Society of Glass Technology, Sheffield. Price* 7*s*. 6*d*.

This excellent publication is more than a mere directory. It includes an alphabetical list of glass manufacturers, makers of scientific glass articles and optical apparatus, craftsmen, firms making plant apparatus and raw materials used in the glass industry, trades unions and other associations concerned in the industry, and periodicals in all countries in which articles or abstracts of interest to glass-makers appear. The various lists appear to be complete and accurate, and it is obvious that great pains have been taken with the preparation of the book. The Society of Glass Technology, the compiler, Mr. G. S. Duncan, and the editor, Prof. W. E. S. Turner, are to be warmly congratulated on their work.

ENGINEERING NON-FERROUS METALS AND ALLOYS. *By* L. AITCHISON, D.Met., *and* W. R. BARCLAY, O.B.E. *Pp. xx*+300. *London: Henry Frowde and Hodder & Stoughton*, 1923. *Price* 21*s*.

The authors have supplied a much-needed book. A certain amount of information on the properties of a limited number of non-ferrous alloys has been available for a very long time, having been accumulated as a result of experience in the working and use of these materials, but when compared with similar knowledge available with regard to iron and steel, this has, until quite recently, been exceedingly meagre. The outstanding features of iron and steel as compared with non-ferrous metals are the much greater strength they exhibit and the profound differences in properties obtained by varying the thermal treatment. The latter feature undoubtedly helped in the past to focus the attention of scientific workers on to steel to the partial neglect of non-ferrous metals. Conditions have now changed and, owing to the general advance of scientific knowledge, to the activities of such societies as the Institute of Metals, and to the influence of war requirements, there has recently been an enormous increase in the exact knowledge of the constitution, properties and

uses of a large range of alloys. The authors have done good service in collecting together a large amount of this information (which has previously only been available after a search through journals and technical papers), and presenting it in a suitable manner for engineers and others interested in the manufacture, treatment and use of non-ferrous metals and alloys.

The book is divided into two parts. Part I is devoted to non-ferrous metals generally, and deals with the properties, constitution, casting, working, heat treatment, mechanical properties and mechanical testing of these alloys. Part II is devoted to a consideration of the various classes of alloys, and deals with copper and its alloys, aluminium and its alloys, nickel and alloys of nickel and miscellaneous non-ferrous alloys. A chapter is also devoted to a consideration of the choice and specification of a non-ferrous alloy.

The vast majority of the non-ferrous alloys in industrial use may be classified as copper, aluminium or nickel alloys from the name of the chief constituent in each case. Of these, the copper alloys are most widely used in engineering industries, and receive a considerable amount of attention by the authors. Aluminium alloys have only become of importance to engineers within recent years, but our knowledge of their properties is already considerable. Nickel alloys have received considerable attention during recent years, as they include some of the strongest, toughest, most durable and most ductile of the non-ferrous alloys. About one-half of the book is devoted to these three classes of alloys and 153 tables of analysis, tests, and other data are included in this portion of the book.

The book may be strongly recommended to all interested in non-ferrous metals and alloys.

C. O. Bannister

COMPANY NEWS

MANDER BROTHERS, LTD.

The business of varnish, colour, paint and printing ink manufacturers formerly carried on by Sir Charles T. Mander, G. le M. Mander, C. A. Mander, G. P. Mander, and H. V. Mander, as "Mander Bros.," is now taken over by Mander Brothers, Ltd., with a registered capital of £600,000, the partners becoming directors of the new company.

SOUTH STAFFORDSHIRE MOND GAS CO., LTD.

The directors' report for the year ended December 31, 1923, states that about 5 per cent. more fuel was gasified and 11 per cent. more gas distributed than during 1922, although trade in the districts served by the company's mains was bad throughout the year. There are now indications of improvement and an increasing demand. The gross profit is £18,468, and after deducting debenture and bank interest, there is a net profit of £9308. During the year the bank overdraft was reduced from £55,991 to £52,211. In view of the amount of the overdraft the directors do not recommend the payment of a preference dividend.—(*Oil & Col. Tr. J.*, 16.2.24.)

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The demand for heavy chemicals is well sustained, but business will, of course, suffer at once from the unfortunate dockers' dispute. Inquiries and orders for the heavy alkalis are particularly good on the export side, in addition to which home consumption is increasing steadily from week to week. There are no fundamental changes in prices to report.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages included.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5½d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports. Business good.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid. In fair request.
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb. Very quiet.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb., according to quality.

Antimony Sulphide (cont.)
Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow 1s. 11d. per lb.
Cadmium Sulphide .. 4s. per lb.
Carbon Bisulphide .. £24—£26 10s. per ton according to quantity.
Carbon Black .. .. Prices continue low but expected to advance in the Spring. Two or three case lots can now be bought at 6½d. per lb. ex wharf. For direct shipment in quantity the price is about 6d. per lb. c.i.f.
Carbon Tetrachloride .. £56 per ton, drums free.
Chromium Oxide .. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark 5d.—7d. per lb. Dearer owing to increased cost of rape seed oil. Good demand.
Lamp Black .. .. 40s. per cwt., barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Thiocarbanilide .. .. 2s. 9d. per lb.
Vermilion, pale or deep .. 3s. 4d.—3s. 6d. per lb.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade and there appears a more healthy prospect in the charcoal market.

Acetate of Lime—
Brown .. .. .. £14 10s. per ton d/d. Demand active.
Grey .. .. .. £22 per ton.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Market quiet.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. „ „ 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 5s. 6d. per gall. 60% O.P. Dull market.
Solvent .. .. 5s. 6d. per gall. 40% O.P. Dull market.
Wood Tar .. .. £5—£6 per ton according to grade. Demand not very brisk. Ample supplies.
Brown Sugar of Lead .. £42 per ton. Demand more active.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 8½d. per lb. Some business passing at lower prices.
Crude 60's .. .. 1s. 10d.—2s. per gall. Firmer, with more inquiry.
Crude 60's .. .. 1s. 10d.—2s. per gall. Little business passing, but more inquiry.
Acid Cresylic, 97/99 .. 2s.—2s. 3d. per gall. Steady business.
Pale 95% .. .. 1s. 10d.—2s. 2d. per gall. Good demand.
Dark .. .. .. 1s. 11d. per gall. Steady business.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 9d.—10d. per gall. Very quiet.
Unstrained .. .. 8½d.—9d. per gall.
Benzole—
Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.
Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 8d.—1s. 10d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 11½d. per gall. Few inquiries.
Middle Oil .. .. } 8½d.—9½d. per gall. according to
Heavy .. .. .. } grade and district. Market
Standard Specification } very firm. Demand good.
Naphtha—
Per gall. } More inquiry.
Solvent 90/160 .. 1s. 1d.—1s. 3d. } Prices show up-
Solvent 90/190 .. 1s. 1d.—1s. 3d. } ward tendency.
Naphthalene Crude—
Drained Creosote Salts £6—£8. Fair business.
Whizzed or hot pressed £8—£14 per ton. Price nominal. No business.
Naphthalene—
Crystals .. .. £16 10s. per ton.
Flaked .. .. .. £17 per ton.
Pitch, medium soft .. 52s. 6d.—62s. 6d. per ton, f.o.b. Market weak. Few sellers.
Pyridine—90/140 .. 14s.—14s. 6d. per gallon. Fewer inquiries.
Heavy .. 11s.—12s. Steady with fair business.

INTERMEDIATES AND DYES

Business in dyestuffs has improved appreciably with orders being given for larger quantities. Prices of intermediates made directly from pure benzol have been raised, owing to the increased cost of the latter.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 6d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 6d. per lb. Better demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 29/31° C. .. 5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Market quiet.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Market quiet.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 3d. per lb. d/d.
Monochlorbenzol .. £63 per ton.
α-Naphthol .. .. 2s. 6d. per lb. d/d.
β-Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 5d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.

m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 5d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 0d. per lb. d/d.
p-Phenylene Diamine	10s. 6d. per lb. 100% basis d/d.
R. Salt	3s. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 7d. per lb. 100% basis d/d.
o-Toluidine	7d.—8d. per lb.
p-Toluidine	3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine	4s. 0d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£52 per ton.
Acid, Acetyl Salicylic	3s. 6d.—3s. 9d. per lb. Steady demand.
Acid, Benzoic	Commercial acid dearer at 2s. 9d. per lb. B.P. quality remains unobtainable.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	18s.—20s. per lb.
Acid, Citric	1s. 5¼d. per lb., less 5% for ton lots. Market firm.
Acid, Gallic	3s. per lb. for pure crystal. Steady market.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	2s. 4d.—2s. 7d. per lb. For ton lots 2s. 3d. is quoted. Market slightly easier.
Acid, Tannic	3s. 3d. per lb. for B.P. quality.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Very firm. Considerable inquiry and buying.
Amidol	9s. per lb. d/d.
Acetanilide	3s. per lb. Weak.
Amidopyrin	14s. per lb. Demand negligible.
Ammon. Benzoate	4s. per lb.
Ammon. Carbonate B.P.	£35 per ton.
AtropineSulphate	12s. 6d. per oz. for English make. Market neglected.
Barbitone	17s. per lb.
Benzonaphthol	5s. 9d.—6s. 3d. per lb. Supplies scarce.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Per lb.
Potassium	9d.—10d. } Steady market.
Sodium	9½d.—10d. } Steady market.
Ammonium	11d.—1s. } Steady market.
Calcium Lactate	2s. 9d. per lb. for best English make. Market firm.
Chloral Hydrate	3s. 9d. per lb. Weak.
Chloroform	2s. per lb. for cwt. lots.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	13s. per lb. for small stocks available. More inquiry. available. Slightly weaker.
Hexamine	3s. 9d.—4s. per lb. for foreign makes.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B. P.	56s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Prices reduced. Market quiet.
Red oxide	4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	3s.—3s. 1d. „
White precip.	4s. 1d.—4s. 2d. „
Calomel	3s. 5d.—3s. 6d. „
Methyl Acetanilide	20s. per lb.
Methyl Salicylate	2s. 11d.—3s. per lb. for carboys. Firmer.
Methyl Sulphonal	22s. per lb.
Methylene di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 8d. per lb.
Phenacetin	7s. per lb. Weaker.
Phenazone	8s. per lb. Dull.
Penolphthalein	7s. 6d. per lb. Weaker.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s.—90s. per cwt., less 2½%. Firm market. Inquiry good.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	9d. per lb. for B.P. crystal English make. In good demand.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. 3d. per lb.
Salol	3s. 9d. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. Ample supplies of British manufacture will soon be available.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity.
Sod. Hyposulphite—Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	76s. 6d.—81s. 6d. per cwt., according to quantity. Prices reduced.
Sod. Salicylate	Powder 2s. 10d.—3s. 1d. per lb., Crystal at 2s. 11d.—3s. 2d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	18s. 6d. per lb.
Tartar Emetic	1s. 4d. per lb.

Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed. Distinctly firmer.	

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	13s. 6d. ,,	
Amyl Acetate	3s. ,,	
Amyl Butyrate	7s. 3d. ,,	
Amyl Salicylate	3s. 6d. ,,	
Anethol (M.P. 21/22° C.)	3s. 9d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. ,,	
Benzyl Alcohol free from Chlorine	3s. 3d. ,,	
Benzaldehyde free from Chlorine	3s. 3d. ,,	
Benzyl Benzoate.. ..	3s. 9d. ,,	
Cinnamic Aldehyde Natural	18s. 6d. ,,	
Coumarin	21s. ,,	
Citronellol	19s. ,,	
Citral	10s. ,,	
Ethyl Cinnamate ..	10s. ,,	
Ethyl Phthalate.. ..	3s. 9d. ,,	
Eugenol	11s. ,,	
Geraniol (Palmarosa) ..	37s. 6d. ,,	
Geraniol	10s.—17s. 6d. per lb.	
Heliotropine	8s. 6d. per lb.	
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose..	20s. ,,	
Linalyl Acetate	20s. ,,	
Methyl Anthranilate ..	8s. 6d. ,,	
Methyl Benzoate ..	6s. ,,	
Musk Ambrette	52s. 6d. ,,	
Musk Xylol	19s. ,,	
Nerolin	4s. ,,	
Phenyl Ethyl Acetate ..	10s. ,,	
Phenyl Ethyl Alcohol ..	16s. ,,	
Rhodinol	65s. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 6d. ,,	
Vanillin	26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	1s. 11d. ,,	
Bergamot Oil	14s. 6d. ,,	
Bourbon Geranium Oil ..	29s. 6d. ,,	
Camphor Oil	75s. per cwt.	
Cananga Oil, Java ..	9s. 4½d. per lb.	
Cinnamon Oil, Leaf ..	5¾d. per oz.	
Cassia Oil, 80/85% ..	9s. 6d. per lb.	
Citronella Oil—		
Java 85/90%	4s. 10d. ,,	
Ceylon	3s. 6d. ,,	
Clove Oil	8s. 9d. ,,	Cheaper.
Eucalyptus Oil 70/75%..	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil	3s. 1d. ,,	
Lemongrass Oil ..	2¾d. per oz.	
Orange Oil, Sweet ..	12s. 6d. per lb.	
Otto of Rose Oil—		
Bulgarian	34s. per oz.	
Anatolian	26s. per oz.	
Palma Rosa Oil	19s. 3d. per lb.	Cheaper.
Peppermint Oil—		
English	70s. per lb.	
Wayne County ..	16s. 6d. per lb.	
Japanese	13s. 9d. per lb.	Advanced.
Petitgrain Oil	9s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents, those of applications, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C.2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY

Applications

A.-G. Kummler u. Matter. Liquid evaporators. 2391. Jan. 29. (Ger., 29.1.23.)

Alexander. High-temperature radiant drying systems, 2230. Jan. 28.

Bishop, and Lilleshall Co. Filter-presses. 3162. Feb. 7.

Cheyne. Mixing and grinding mills. 2304. Jan. 29.

Clapham and Clare. Apparatus for purifying gases. 2819. Feb. 4.

Dempster and Sons, and Toogood. Regenerator furnaces. 2510. Jan. 31.

Dini. Producing agglomerates for compressing into moulds. 2252. Jan. 28. (Ital., 29.1.23.)

Fuller. Drying apparatus. 3368. Feb. 8.

Geisel. Solvent recovery plant. 2543. Jan. 31. (Ger., 28.3.23.)

Haneman and Speichert. Vacuum furnaces. 2272. Jan. 28. (Ger., 17.2.23.)

Kautny. Apparatus for liquefying and separating gases. 2220. Jan. 28.

Koppers Coke Oven Co. Apparatus for washing liquids with liquids. 2355. Jan. 29. (Ger., 30.1.23.)

Low, and Low Engineering Co. Mixing-apparatus. 2677. Feb. 1.

Major and Taylor. Distillation etc. of liquids. 3208. Feb. 7.

Mewes and Mewes. Separation of gas mixtures. 2908. Feb. 4.

Paterson. Filtering apparatus. 2382. Jan. 29.

Complete Specifications Accepted

19,845 and 27,715 (1922). Shaw. Separating and removing matter suspended in a fluid. (210,101.) Feb. 6.

28,250 (1922). Rigg and McBride. *See* X.

33,296 (1922) and 17,944 (1923). Taylor and Oldfield. Gas-cleaning apparatus. (210,233.) Feb. 6.

5957 (1923). Agthe. Continuous production of emulsions, suspensions, and similar disperse systems. (210,307.) Feb. 6.

9392 (1923). Maison Beer, and Charlior. Separating, washing, and classifying solid materials. (210,663.) Feb. 13.

18,071 (1923). Fraser and Egleston. Grinding or mixing apparatus. (210,702.) Feb. 13.

24,976 (1923). Loke. *See* VIII.

26,806-7 (1923). Shaw. Separating and removing matter suspended in a fluid. (210,376.) Feb. 6.

II.—FUEL; GAS; DESTRUCTIVE DISTILLATION MINERAL OILS; LIGHTING

Applications

Alden and Green. Gas-producers. 3381. Feb. 9.

Bettisfield Trust Co., and Perkin. Distilling and carbonising coal etc. 2590. Jan. 31.

Black. Extraction of oils, spirits, and gases from polionite, shale, etc. 2487. Jan. 30.

Briketthar z-Ges. Manufacture of combustible briquettes. 2267. Jan. 28. (Ger., 29.1.23.)

British Electrical and Allied Industries Research Assoc. 3363. *See* XI.

Bruce. Carbonisation etc. of wood. 3092. Feb. 6.

Clapham and Clare. 2819. *See* I.

Donald. Drying peats etc. 26[illegible] and 3432. Feb. 1 and 9.

Evans. Briquette binders. 31[illegible]. Feb. 7.

Fabry. Coke-oven heating flues. 2805. Feb. 4.
Fabry. Purification of coal-gas. 3159. Feb. 7.
Gros. Manufacture of hydrogen and acetylene. 2759. Feb. 2. (Fr., 8.2.23.)
Gros. Pyrogenic transformation of acetylene or gaseous mixtures derived from acetylene. 2760. Feb. 2. (Fr., 14.2.23.)
Hanna. Manufacture of carbon black. 3135. Feb. 6.
Hersey, Stokes, and Kirkham, Hulett, and Chandler. Gas washer-scrubbers. 3427. Feb. 9.
Hinselmann. Obtaining products from fuels, oil shale, etc. 3379. Feb. 8. (Ger., 6.6.23.)
Hydro-Carbon Distillation Synd., Knapp, and Winzer. Distillation of oils etc. 3115. Feb. 6.
Kernot. Treatment of hydrocarbon-yielding materials. 2369. Jan. 29.
Knapen. Washing coal dust etc. 3300. Feb. 8. (Belg., 8.2.23.)
Koppers Coke Oven Co. (Koppers). Continuously distilling liquid hydrocarbons. 3446. Feb. 9.
Lamplough and Porter. Conversion of heavy hydrocarbons into lighter hydrocarbons. 2698. Feb. 1.
Lederer. Manufacture of filamentary incandescing bodies. 2268. Jan. 28. (Austria, 21.2.23.)
Loebell. Manufacture of combustible gas. 2567-8. Jan. 31.
Mackay. Bituminous emulsions. 3312. Feb. 8.
Odell. Gas-producer. 3305. Feb. 5.
Syndikat f. Gasforschung. Dry distillation of bituminous fuel. 2694. Feb. 1. (Ger., 1.2.23.)
Umpleby. Gas-generators. 3039. Feb. 6.
Wallace. Treatment of liquid hydrocarbons, oils, or fats. 2704. Feb. 1.
Whitfield. Suction-gas producers. 3281. Feb. 8.

COMPLETE SPECIFICATIONS ACCEPTED

20,827 (1922) and 1123 (1923). Woodall, Duckham, and Jones, and Duckham. Briquetting fuel. (210,466.) Feb. 13.
23,948 (1922). Sutcliffe. Machines for briquetting, compressing, etc. coal etc. (210,474.) Feb. 13.
25,377 (1922). Aguillon. Recovery of benzol from coal gas. (210,114.) Feb. 6.
28,225 (1922). Marks (Chem. Research Synd.). Production of hydrocarbons of relatively low boiling point. (210,131.) Feb. 6.
28,963 (1922). Electrical Improvements, Ltd., and Merz. Fuels. (210,147.) Feb. 6.
33,296 (1922) and 17,944 (1923). Taylor and Oldfield. *See* I.
7728 and 12,672 (1923). Heyl. Utilisation of the carbon residue of distillation retorts. (210,317.) Feb. 6.
14,260 (1923). Mond (American Shale Reduction Co.). Extracting volatile matter from oil-bearing shale etc. (210,691.) Feb. 13.
16,960 (1923). Travers and Clark. Manufacture of gas from coal etc. (210,356.) Feb. 6.
18,092 (1923). Meister, Lucius, u. Brüning. Manufacture of highly-active charcoal. (201,163.) Feb. 13.

III.—TAR AND TAR PRODUCTS

COMPLETE SPECIFICATIONS ACCEPTED

25,377 (1922). Aguillon. *See* II.
28,225 (1922). Marks. *See* II.

IV.—DYESTUFFS AND INTERMEDIATES

APPLICATIONS

Chem. Fabr. Griesheim-Elektron. 2377. *See* VI.
Coke and Maxted. Manufacture of phthalimide. 2713. Feb. 2.
Colloisil Colour Co. (Eberlein). Manufacture of silicates of basic dyestuffs. 3249. Feb. 7.
Imray (Meister, Lucius, u. Brüning). Manufacture of indigoid vat dyestuffs containing sulphur. 2279. Jan. 28.
Imray (Soc. Chem. Ind. Basle). Manufacture of indigoid dyestuffs. 2474. Jan. 30.
Scottish Dyes, Ltd., Thomas, and Thomson. Dyestuffs. 3021. Feb. 5.
Soc. Chem. Ind. Basle. Manufacture of a thionaphthisatin. 2379. Jan. 29. (Czech., 29.11.23.)
Soc. Chem. Ind. Basle. Manufacture of an indigoid dyestuff. 2473. Jan. 30. (Swiss, 9.2.23.)

COMPLETE SPECIFICATIONS ACCEPTED

26,021 (1922) and 16,634 (1923). Masters. Manufacture of β-naphthol 2.3.6- and 2.6.8-disulphonic acids. (210,120.) Feb. 6.
32,090 (1922). Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of azo-dyestuffs. (210,217.) Feb. 6.
10,894 (1923). Imray (Soc. Chem. Ind. Basle). Manufacture of dyestuffs derived from pyrazolone. (210,669.) Feb. 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER

APPLICATIONS

Alsa Soc. Anon. Manufacture of artificial threads. 2699. Feb. 1. (Fr., 13.4.23.)
Bader, Eggert, and Wagner. Manufacture of artificial silk etc. fabrics from viscose. 3404. Feb. 9.
Bergen. Manufacture of viscose threads etc. 3196. Feb. 7. (Holland, 7.2.23.)
Courtaulds, Ltd., and Hegan. Manufacture of filaments etc. from cellulose compounds. 2758. Feb. 2.
Nebrich. Apparatus for separating cellulose etc. 3147. Feb. 6.
Pokorny. Treatment of material of cellulose fibres. 2264. Jan. 28.
Soc. de Stéarinerie et Savonnerie de Lyon. Manufacture of cellulose esters. 3112. Feb. 6. (Fr., 31.7.23.)
Strüdel. Machine for dissolving or unthreading fabrics etc. 2705. Feb. 1.

COMPLETE SPECIFICATIONS ACCEPTED

19,647 (1922) and 10,535 (1923). Cook and Co., and Cook. Treatment of cotton etc. (210,100.) Feb. 6.
20,003 (1922). Kampf. Manufacture of artificial threads etc. of viscose. (184,449.) Feb. 6.
21,915 and 27,083 (1922). Dreyfus. Manufacture of artificial silk, artificial horsehair, etc. (210,108.) Feb. 6.
29,245 (1922). Medhurst. Manufacture of paper. (210,166.) Feb. 6.
29,491 (1922). Fues. Manufacture of water-resisting paper. (187,987.) Feb. 13.
29,885 (1922). Schidrowitz. Manufacture of paper etc. (210,526.) Feb. 13.
1029 (1923). Dreyfus. Manufacture or treatment of artificial threads. (210,266.) Feb. 6.
17,967 (1923). Soc. Chim. Usines du Rhône. Removal of size from cellulose acetate silk etc. (206,113.) Feb. 6.

VI.—BLEACHING; DYEING; PRINTING; FINISHING

APPLICATIONS

Chem. Fabr. Griesheim-Elektron. Producing on the fibre azo dyes from arylamides of 2.3-hydroxynaphthoic acid. 2377. Jan. 29. (Ger., 22.1.23.)
Lindsay. Steaming, ageing, etc. 2365. Jan. 29.

COMPLETE SPECIFICATIONS ACCEPTED

24,602 (1922). Durand et Huguenin. Manufacture of products for dyeing or printing. (186,057.) Feb. 13.
30,452 (1922). Davies and Haigh. Scouring, bleaching, dyeing, carbonising, etc. (210,545.) Feb. 13.
8933 (1923). Brandwood, Brandwood, and Brandwood. Dyeing and subsequent handling of yarns wound in the form of cheeses. (210,601.) Feb. 13.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS

Applications

Casale. Synthesis of ammonia. 2608. Jan. 31.
Chem. and Metallurgical Corp., and Smith. Treatment of lead chloride etc. 2472. Jan. 30.
Chem. Fabr. Grünau, Landshoff u. Meyer. Manufacture of cast and moulded articles from borates etc. 2255. Jan. 28. (Ger., 12.2.23.)
Gros. 2759. *See* II.
Makow and Wolffenstein. Production of hydrogen peroxide. 2782. Feb. 2.
Soc. Chim. Usines du Rhône. Manufacture of alkalinoearth arsenates. 2581 and 3230. Jan. 31 and Feb. 7. (Fr., 15.5.23 and 27.4.23.)

Complete Specifications Accepted

20,353 (1922). Scott. Manufacture of hydrogen and oxygen. (210,102.) Feb. 6.
29,040 (1922). Roberts. Manufacture of lime. (210,153.) Feb. 6.
3476 (1923). Cocksedge (Sundstrom and Tirziev). Manufacture of a sodium compound. (210,628.) Feb. 13.
6595 (1923). Henkel et Cie., and Weber. Treatment of iron chloride lyes. (195,947.) Feb. 6.
14,508 (1923). Titan Co. Akt. Treatment of titanium-nitrogen compounds. (199,713.) Feb. 13.
18,250 (1923). Vogel. Manufacture of colloidal sulphur. (210,363.) Feb. 6.

VIII.—GLASS; CERAMICS

Applications

Chem. Fabr. Grünau. 2255. *See* VII.
Comp. Générale des Cables de Lyon. Enamelling wire. 3253. Feb. 7. (Ger., 5.4.23.)
Royer. Furnaces for baking pottery. 2945. Feb. 5.

Complete Specifications Accepted

23,956 (1923). British Thomson-Houston Co. (General Electric Co.). Working quartz. (210,707.) Feb. 13.
24,976 (1923). Loke. Furnace linings, crucibles, etc. 210,708.) Feb. 13.

IX.—BUILDING MATERIALS

Applications

Angelis. Heat-insulating material. 2269. Jan. 28. (Fr., 27.1.23.)
Bercott. Manufacture of artificial stone. 2638. Feb. 1.
Evans, Simkin, and Perfect Kiln Co. Brick etc. kilns. 2409. Jan. 30.
Heyl. Cement. 2584. Jan. 31.
Mackay. 3312. *See* II.

Complete Specifications Accepted

29,041 (1922). Roberts. Portland cement compositions. (210,154.) Feb. 6.
13,675 (1923). Zimmer and Frankl. Manufacture of artificial asphalt-limestone. (210,343.) Feb. 6.
18,940 (1923). Patrouilleau. Manufacture of bauxite cements. (210,366.) Feb. 6.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY

Applications

Bedford. Rendering metals rustless. 2791. Feb. 2.
Boucher and Shorter. Heat treatment of steel articles. 3080. Feb. 6.
Chemical and Metallurgical Corp., and Smith. Treatment of ores etc. containing zinc. 2376. Jan. 29.
Comp. Gén. des Cables de Lyon. 3253. *See* VIII.
Dürkoppwerke A.-G. Iron separation and desulphurising in cupola furnaces. 3034. Feb. 5. (Ger., 5.3.23.)
Fox. Treating surface of bronze etc. 2878. Feb. 4.
Levoz. Direct reduction of iron ores. 2686. Feb. 1. (Belg., 1.2.23.)
Marks (Sumet Corp.). Metallic composition. 2904. Feb. 4.
Marks (Sumet Corp.). Purifying metals. 2905. Feb. 4.
Martin, and Sankey and Sons. Pickling stainless steel etc. 2205. Jan. 28.
Meker. Manufacture of metals coated with aluminium etc. 2601. Jan. 31. (Fr., 7.2.23.)
Ormiston. Alloy. 2441. Jan. 30.
Perkins and Taplin. Treatment of ores containing oxidised copper compounds. 2322. Jan. 29.
Sumpter, and Vickers, Ltd. Surface-hardening steel articles. 3243. Feb. 7.

Complete Specifications Accepted

25,973 (1922). Meehan. Manufacture of grey iron. (210,118.) Feb. 6.
28,250 (1922). Rigg and McBride. Drying ores, concentrates, etc. (210,133.) Feb. 6.
29,616 (1922). Fink. Composite metal articles or materials. (210,508.) Feb. 13.
29,785 (1922). British Aluminium Co., and Gwyer. Aluminium alloys. (210,517.) Feb. 13.
34,251 (1922). Sulman and Picard. Froth-flotation test apparatus. (210,245.) Feb. 6.
34,716 (1922). Archer and Jeffries. Aluminium base alloys. (190,721.) Feb. 13.
20,595 (1923). Katsumori. Manufacture of porous iron. (210,369.) Feb. 6.
29,567 (1923). Foerster. Art of electro-plating. (207,544.) Feb. 13.

XI.—ELECTRO-CHEMISTRY

Applications

British Electrical and Allied Industries Research Assoc. and Flight. Insulating and lubricating oils. 3363. Feb. 8.
Eltax Elektro A.-G. Electric batteries. 2372. Jan. 29.
Leitner. Electric accumulators. 2861. Feb. 4.
Pehrson. Electric furnaces. 2259. Jan. 28.
Tribelhorn. Filling paste for lead accumulators etc. 2389. Jan. 29. (Switz., 1.2.23.)
Wade (Nederlansch Techn. Handel Maatsch. Giro). Manufacture of electric resistance material. 3033. Feb. 5.

Complete Specifications Accepted

34,747 (1922). Oldham and Son, and Wilde. Galvanic batteries. (210,593.) Feb. 13.
605 (1923). Case. Light-reactive cells. (210,604.) Feb. 13.
7259 (1923). Soc. Anon. Lo Carbone. Electric battery cells. (197,301.) Feb. 6.
7651 (1923). Chloride Electrical Storage Co., and Dean. Electric accumulators. (210,316.) Feb. 6.
7981 (1923). Wild and Barfield. Electric furnaces. (210,652.) Feb. 13.
19,952 (1923). Pepper. Electric batteries. (201,933.) Feb. 13.
29,567 (1923). Foerster. *See* X.

XII.—FATS; OILS; WAXES

Applications

McNicoll. Treating crude cotton oils etc. 3070. Feb. 6.
Wallace. 2704. *See* II.

XIII.—FATS ; OILS ; WAXES

APPLICATIONS

Barber. Manufacture of lac. 3307. Feb. 8.
Edser and Marshall. Paints. 3364. Feb. 8.
Evans. Separation of kauri gum from foreign matter. 2787. Feb. 2.
Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of sulphobenzyl esters of resinous condensation products from phenols. 3237. Feb. 7. (Ger., 7.2.23.)
Shepherd. Production of paint. 2717. Feb. 2.

COMPLETE SPECIFICATION ACCEPTED

20,265 (1922). Shawinigan Laboratories. Phenolic condensation products. (183,830.) Feb. 6.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA

APPLICATIONS

Anode Rubber Co. Production of rubber sheets etc. from latex. 2773 and 2783. Feb. 2.

COMPLETE SPECIFICATIONS ACCEPTED

29,202 (1922). Plauson's (Parent Co.), Ltd. (Plauson). Colouring of rubber. (210,495.) Feb. 13.
22,351 (1923). Frerichs. Production of a substance resembling ebonite or vulcanite. (203,695.) Feb. 13.

XV.—LEATHER ; BONE ; HORN ; GLUE

COMPLETE SPECIFICATIONS ACCEPTED

25,275 (1922). Duckworth. Treatment of skins. (186,608.) Feb. 6.
9507 (1923). Soc. Anc. Etabl. A. Combe et Fils et Cie. Production of washable printings on leather. (207,778.) Feb. 6.

XVI.—SOILS ; FERTILISERS

COMPLETE SPECIFICATION ACCEPTED

14,304 (1923). Coppée et Cie. Production of mixed manure using distillers' wash etc. (200,070.) Feb. 6.

XVII.—SUGARS ; STARCHES ; GUMS

COMPLETE SPECIFICATIONS ACCEPTED

20,168 (1922). Sauer. Treatment of sugar juices. (183,485.) Feb. 13.
33,252 (1922). Russell. Filtration or decolorisation of sugar etc. (210,232.) Feb. 6.
14,400 (1923). Mitchell and Wuthrich. Extraction of juice and obtaining fuel from sugar cane. (210,692.) Feb. 13.

XVIII.—FERMENTATION INDUSTRIES

COMPLETE SPECIFICATIONS ACCEPTED

12,805 (1923). Continentale Industrie Verwertung Ges. See XIX.
14,304 (1923). Coppée et Cie. See XVI.

XIX.—FOODS ; WATER PURIFICATION ; SANITATION

APPLICATIONS

Heyerdahl. Preservation of milk etc. 2624. Feb. 1.
Heyerdahl. Production of edible products rich in vitamins. 2728. Feb. 2.
Heyerdahl. Manufacture of food products containing vitamins. 2729. Feb. 2.
Heyl. Purification of sewage etc. 2583. Jan. 31.
Huch. Manufacture of preserved goods. 2311. Jan. 29.
Sando. System for treating activated sludge. 2562. Jan. 31. (U.S., 5.2.23.)

COMPLETE SPECIFICATIONS ACCEPTED

26,652 (1922). Benoit. Purification of liquids. (210,480.) Feb. 13.
33,324 (1922). Marsan. Manufacture of substitutes for meat extract and meat powder. (190,147.) Feb. 13.
12,805 (1923). Continentale Industrie Verwertung Ges. Manufacture of food products from yeast. (197,695.) Feb. 6.
17,388 (1923). Imray (Soc. Chem. Ind. Basle). Manufacture of alkaline-earth metal compounds of the organic phosphorus compound of milk casein. (210,698.) Feb. 13.

XX.—ORGANIC PRODUCTS ; MEDICINAL SUBSTANCES ; ESSENTIAL OILS

APPLICATIONS

Chemosan A.-G. Production of solutions of mercury derivatives of hydroxybenzenesulphonic acids for therapeutics etc. 2276. Jan. 28. (Austria, 30.4.23.)
Dreyfus. Manufacture of organic compounds. 2454 Jan. 30.
Johnson (Badische Anilin u. Soda Fabr.). Manufacture of methyl alcohol etc. 3326. Feb. 8.

COMPLETE SPECIFICATIONS ACCEPTED

31,786 (1922). Loriette. Process for dehydrating alcohol (189,453.) Feb. 13.
17,388 (1923). Imray (Soc. Chem. Ind. Basle). See XIX

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES

APPLICATIONS

Major. Photographic developers. 3419. Feb. 9.
Martinez. Self-fixing photographic papers. 2847. Feb. 4
May. Taking and reproducing pictures in natural colours 3256. Feb. 7. (Austria, 8.2.23.)
Tompkins. Production of photographic images. 2413 Jan. 30.

COMPLETE SPECIFICATIONS ACCEPTED

29,053 (1922). Hydroloid, Ltd. (Exportingenieure f. Papier u. Zellstofftechnik). Sensitised papers and the manufacture thereof. (210,493.) Feb. 13.

TRADE NOTES

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

Australia.—Oils, chemicals, dyes, rubber, crockery (Refs. 412/7/1/1/210 and 412/7/1/1/211, Official Secretary, Commercial Bureau, Australia House, Strand, W.C. 2) ; *Belgium.*—Metallurgical products (180), steel rails (21994/F.W./E.P.) ; *Danzig :* Oils (182) ; *Egypt :* Paint, oil, varnish (12352/F.E./G.C.) ; Paint, saddlery, cellulose (12407/F.E./G.C.) ; *Netherlands :* Iron and steel (185) ; *New Zealand :* Leather (176) ; Hardware, earthenware, enamel ware, china (177) ; Copper wire, vulcanised rubber (13096/E.D./CC.) ; *Poland :* Oils (182) ; *South Africa :* Brass, tyres, paper (High Commissioner for the Union of South Africa, London) ; *Spain :* Chemicals (195) ; Drugs, pharmaceutical products, rubber (196) ; *Uruguay :* Fuel oil (9346/F.L./C.C.2).

FRANCE

French Market News

Prices of turpentine are well maintained, and it appears that all stocks will be cleared before the new production appears on the market; the price on February 11 was 6·20 francs. A similar tendency holds with resins (price on February 11 W.W. 155 frs.). Numerous purchases of resins have been made by English houses, and the low stocks may lead to a rise in prices.

Nitrogen Fixation

The French Senate recently discussed the proposed agreement for the manufacture of synthetic ammonia and it appears that the Senate wishes to replace the company proposed by the Chamber of Deputies (*cf. Chem. and Ind.*, p. 228, 1923) by a National Nitrogen Office under the Ministry of Finance. This Office would be controlled by Parliament, to which its accounts would be presented each year.

Mining and Metallurgy in December

The following are statistics of production in December, 1923: Bauxite, 32,272 metric tons; iron ore, 2,034,759 t.; iron pyrites, 14,992 t.; coal and lignite, 3,346,690 t. (plus coke, 189,532 t.; briquettes, 263,324 t.); iron, 564,665 t. (536,749 t. in November); steel, 525,509 t. (an increase of 32,982 t. over November).

Imports of coal during December were: Coal and lignite, 2,347,524 t.; coke, 357,252 t.; briquettes, 79,383 t., compared with exports of 227,696 t. of coal; 45,678 t. of coke, and 14,073 t. of briquettes.

German Deliveries of Fuel

German deliveries of fuels to France and Luxemburg during 1923 comprised 1,690,000 tons of coal; 2,276,500 t. of coke, and 156,800 t. of lignite briquettes a total of 4,123,000 t. compared with deliveries in 1922 of 12,632,265 t. The delivery was fixed by the Reparations Commission at an annual total of 14,918,800 t., so that deliveries in 1923 were only 28 per cent. of the agreed amount.

Absolute Alcohol

Until 1921, absolute alcohol was solely a laboratory product, but the experiments on mixtures of petrol and alcohol with a view to developing the new motor fuel led to the examination of processes for producing alcohols of over 99·6°. In one process due to Monsieur Loriette, the alcohol is dehydrated in the cold by potassium carbonate, the potassium carbonate being regenerated by heating to from 133 to 140°. By warming with quicklime a similar result can be obtained. In the process due to Professor Young, the ternary azeotropic mixture of 18·5 per cent. alcohol, 74 per cent. benzene, and 74 per cent. water is distilled, the first distillation removing the water, the second removing the benzene, leaving pure alcohol. This method has been applied on an industrial scale by MM. Barbet and Delemard. Glycerin is also used to obtain absolute alcohol, as in the Van Ruijmecke process (1921). MM. E. and R. Urbain utilised the velocity of diffusion through porous walls to obtain an alcohol up to 99·8° in an apparatus which combines distillation with atmolysis.

INTERNATIONAL PAINT CO.

The profit of the International Paint and Compositions Company for 1923, after writing off bad debts, was £55,689, less income-tax £3082, and provision for depreciation fund, £5677, leaving £46,929, plus £3798 brought in, making £50,727. Directors recommend transferring to reserve fund £15,000, dividend of 5 per cent. on Ordinary shares for year, carrying forward £4727.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, FEBRUARY 29, 1924

EDITORIAL

We have read with much interest Prof. W. A. Noyes' little book, "Building for Peace II." As an American Professor of Chemistry who has recently lived for many months in France, has repeatedly visited England and has many friends in those two countries and in Germany, he is able to approach the subject in a dispassionate and broad-minded manner. A better understanding between all countries is slowly coming about, and a pamphlet such as this is helpful, but no such literature can hasten the progress very much. So far as European politics is concerned, we all have our own views, whether our knowledge of history, politics or economics justifies them or not. This great problem is outside the province of *Chemistry and Industry*, but nevertheless chemists may do a good deal towards promoting a better understanding between the English-speaking and the various Continental chemists, and there is no reason why *Chemistry and Industry* should not play its part in such a desirable enterprise. So far as concerns all countries, except Austria and Germany, their chemists meet once a year at the Congresses of the Union Internationale de la Chimie Pure et Appliquée, and this body has already played an important part, and is destined to play a still more important part in the future. Let us face the unpleasant parts of the landscape fairly and dispassionately. The Union Internationale meets next summer in Copenhagen; now a good many Danes believe, rightly or wrongly, that Denmark during the last sixty years and even during the last ten years, has been badly treated by Germany. This is a matter of history and politics, not of chemistry, but it is unfortunate all the same. Have the German men of science identified themselves with the doings of the German Government in this respect? In some measure by their famous manifesto, we fear that they have. Would it not be desirable that the German chemists should try to put themselves in the right, *vis-à-vis* their Danish neighbours? It would not be difficult for them to take some steps in this direction, if they wish to promote a better understanding. As between the German and the French chemists this is more difficult. Both nations have serious and important grievances. During the last sixty years France has twice been invaded by Germany in a manner which we suppose no intelligent chemist in either country would now defend, and the French chemists are, rightly or wrongly, of opinion that Germany has not done all in her power to repair the damage caused by the German Government, and they consequently, the majority of them, approve of, at any rate, some of the steps taken by the French Government in the occupation of the Ruhr and other districts. The German men of science on the whole—there must, without doubt, be exceptions—publicly proclaimed their approval of the acts of the German Government which had such unfortunate results to the harmony of European chemistry. We do not know whether they still approve of them, but if half-a-dozen or ten of the leading German chemists were to write a letter to us merely, and briefly, expressing their regret that France was invaded in 1914, and the succeeding years, and that the property of chemists was destroyed in the way it was, their letter through our columns would immediately be circulated in every European country and would have a good effect. Such a letter need not be an admission that all the faults were on one side, nor need it deal with those matters of policy which properly belong to the domain of history, but it would be an indication that some of the chemists in the year 1924 are able now to realise that the hopes, ambitions and methods of the German Government of the year 1914 were not in accordance with those peaceful ideas of progress with which science and, in particular, chemistry has already achieved so much.

* * *

The difficulty in the case of Germany and Belgium is very much the same. In the case of all other countries the obstacles to a good understanding of chemists are of trifling importance. We have only to look at the situation in Holland, Austria, Poland, Italy, Sweden, Switzerland and Czecho-Slovakia to realise that there is no cause in those countries to interfere with agreeable international relations between chemists. In spite of differences of language, of modes of thought, of political views, and of many other differences, the friendship between English and French chemists steadily grows. There is no reason why the German chemists, if they wish—as we assume they do—to co-operate with the other chemists of the world for the advancement of science, should not give the world some slight indication that they do not now identify their views with the views of the late German Government, and there is every reason why they should co-operate with us with the same friendliness, the same fairness, the same willingness to acknowledge the achievements of other countries, the same unalloyed scientific spirit which is characteristic of the Union Inter-

nationale. The chemists of countries which have produced such men as Arrhenius, Avogadro, Bunsen, Cailletet, Crookes, Curie, Davy, Dumas, Faraday, Fischer, Hofmann, Langmuir, Lewis, Liebig, Mendeléef, Moyer, Millikan, Ostwald, Pasteur, Perkin, Perrin, Ramsay, Stas, Van't Hoff, and scores of others should be large-minded enough to work together, so far as chemistry is concerned, quite apart from the political differences which separate their respective countries. We hope that German chemists will always be good citizens and supremely patriotic, that they will have a due, and even an undue, pride in their country, its history and its achievements, but in their purely chemical pronouncements and in their official chemical literature, it is prudent as well as neighbourly to eliminate all political theories and propaganda. The discovery of the cure for sleeping sickness, " Bayer 205," was an important and interesting scientific piece of work. The Association of Tropical Diseases might with advantage have refrained from publishing its Hamburg declaration that the other countries should only participate in this discovery conditionally on the restoration to Germany of her colonial empire. We could recall other instances but we refrain, hoping that these ideas belong to the past and not to the future.

* * *

Our correspondent J. V. M. makes us sigh. There is no pleasing some people ; they do not wish to be pleased, they prefer to be free to criticise. We cannot imagine there are many chemists who think like J. V. M., at any rate, not in London. A few visits to the Chemical Industry Club would dispel many of his delusions. " Fleet Street," said Dr. Johnson, " has a very animated appearance, but I think the full tide of human existence is at Charing Cross." Let J. V. M. seek the full tide in that vicinity, but to save him trouble, we will at once answer some of the points in his letter. The Federal Council was discussed by a few chemists prior to the year 1918, and in November that year a preliminary meeting was held to form such a body. The details required some considerable lapse of time, and the first meeting of the Council was not held until November, 1919, when Sir William Pope was elected President. The rules provide for twenty-five elected members and not more than six co-opted ones in addition. The Chemical Society elects three, the Society of Chemical Industry elects three, the Association of British Chemical Manufacturers elects three, the Iron and Steel Institute two, the Institute of Chemistry one, the Society of Public Analysts, the Faraday Society, the Ceramic Society, the Dyers and Colourists, and some other societies one each. Such members hold office for three years and are eligible for re-election. The President is elected by the Council, and may not hold office for more than five consecutive years. The Council now consists of the following: Sir William Pope, Professors Philip, Armstrong and [illegible]pe, Sir Robert Hadfield, Sir Thomas Rose, Sir Herbert Jackson, Sir Robert Robertson, and Messrs. Carr, Woolcock, Miall, Armstrong, Evans, Bolton, Cooper, Chaston, Chapman, Cross, Turner, Harbord, Drummond, Mellor, Colman, Wood, Prior, Voelcker, Forster, Mond and Coley. There is only one Committee, whose sole function is the collection of the Fund, so that every member of the Council has an equal opportunity of taking part in the decisions of the Council. It is true that most of the members are busy men, but they manage somehow to attend to the business of the Federal Council. As to the Federal Council being run by a clique, we suppose our correspondent means that the bulk of the work falls on some dozen men who contrive to attend a fair proportion of the meetings—even in their case the night comes so soon that half they propose very seldom is done. Stop, reader, and sigh while thou thinkest on the rest ! Now what are the objects of the Federal Council ?

First, to act as the British organisation of the Union Internationale de la Chimie Pure et Appliquée. It is to be representative in some way for international purposes of British chemistry, and to send a suitable British delegation to attend the Annual Meetings of the Union Internationale. Last year the Federal Council invited the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry to choose the delegation. It is probable that those three Societies are as competent to choose the delegates as any organisations in the country. Next, the Federal Council strives to effect such co-operation between the various chemical bodies as is possible. It is obvious that until there is a great deal of such co-operation the duties of the Federal Council, as representing all organised chemistry, are light and vague. As matters are constituted now, if some community of action seems to be possible between, say, the Chemical Society and the Faraday Society, or the Gas Engineers and the Biochemists, the utmost the Federal Council can do is to discuss informally the possibilities and suggest a joint committee of the two bodies to investigate the practicability. It is hard work for those who serve on such a committee ; many of the members are towards the close of the day tired with the exposition of chemistry, and the few who have a scheme resemble the man who "thought of convincing while they thought of dining." In any case, it is not easy for the Federal Council to advertise the consideration of such an idea. The matter becomes the concern of the two Societies involved, and in the fulness of time their decision is duly announced in their special Transactions. The Federal Council has been helpful in many instances of this character, but its real work will not begin until Chemistry House is a reality. It seems to us the Federal Council has done much to keep this project in the minds of chemists. As to the secrecy with which its doings are shrouded, a hasty glance through our pages reveals some news about the Federal Council on pages 461, 473, 709 and 1071 of our *Journal* last year, and on page 135 of this year. We can ill afford greater space, and the Honorary Secretary of the Federal Council informs us that he blushes to ask for as much as he has received. Some progress in co-operation is already achieved, and the Bureau of Chemical Abstracts may thrust more upon us. Nevertheless, it takes time, and while we plan, and plan, our hair is grey before we know it.

MAGNESIUM OXYCHLORIDE CEMENT

By J. H. PATERSON, D.Sc., F.I.C.

Discovered in 1868 by the French chemist Sorel, magnesium oxychloride has long been recognised as a cement with unique and very valuable properties. It is, in fact, the strongest cement available which is cheap enough to be used on a large scale. It is rather astonishing, therefore, that so little is known or has been written about this very useful material and it is the purpose of this article to set out some of its more important features and applications.

When magnesium oxide in a proper physical condition is mixed with a sufficient quantity of a dilute solution of magnesium chloride to form a plastic mass, the whole sets in a few hours to a hard stone-like solid. This setting is brought about by the combination of the two constituent materials with water to form the compound, magnesium oxychloride. It is not possible to express the composition of this substance by an exact formula, but it probably consists mainly of the compound 3 MgO. $MgCl_2$. 10 H_2O mixed with various solid solutions of a more basic nature. It will be seen that this cement differs from the more commonly used Portland cement and plaster of Paris in that a chlorine compound is required to complete the setting, in addition to the usual water.

Sorel cement, as this material is often called, has very remarkable properties. The neat cement can be made nearly twice as strong as Portland cement and its binding powers are so great that it can be made to hold together very large volumes of filling materials, such as the sand and stones commonly used when making concrete, or if required, saw-dust, cork-dust and leather waste. In fact so much saw-dust, for example, can be bound together into a solid and strong mass that a most important use of this cement is to produce a hard floor covering which has some of the properties of wood, in that it is not too cold to the feet and can have nails and screws driven into it without trouble.

In this country the use of this wood substitute was almost exclusively confined in pre-war days to the shipbuilding industry; large areas in the living quarters of merchant vessels were covered by such materials as Litosilo, Veitchii and Dexton, these being the trade names for varieties of Sorel-cement flooring. The finished floor was generally stained to a dull red colour and very often was merely polished in order to keep it clean.

During the war the shortage of timber led to an extended use of these and similar preparations, and with the advent of the housing schemes a great impetus was given to their application, particularly in laying the ground level floors of cottage and working class properties. In America, Germany and France a good deal of exterior stucco work is carried out in this material, but so far it has not found much favour for this purpose in Great Britain.

The magnesia sold for the manufacture of this cement is made by calcining magnesite rock at a carefully controlled temperature. In pre-war days the bulk of the magnesia used in this country was imported from Hamburg and was there made by the calcination of magnesite rock imported from Euboeia, one of the Grecian Isles. During the war a large amount of magnesite was shipped from India and calcined in this country, but it did not yield a very satisfactory product, and the high cost of carriage has made its use prohibitive since that period. At the present day a certain amount of Grecian magnesite is calcined in Scotland, but the German material is again coming across in increasing quantities.

A good quality magnesia is manufactured from selected stone only. This after breaking up, is carefully hand-picked to remove impurities and then calcined in special furnaces at temperatures regulated between 750° C. and 950° C. The calcined material is again sorted to remove overburned pieces and ground in tube or ball mills to the required degree of fineness.

The product is placed on the market in this country as fine ground calcined magnesite, or in America, as plastic magnesite.

If the temperature of burning is carried above 1000° C., the resulting magnesite will not re-act with magnesium chloride, so that a clear distinction must be made between magnesite burned for cement making, and that which is burned for the manufacture of refractory materials.

A long experience of commercial calcined magnesite has led to the conclusion that a large number of tho faults which develop from time to time in oxychloride cements, is due to the improper burning of the raw material. The kilns, frequently of the beehive type, are so constructed that at the comparatively low temperature required, even distribution of heat is impossible, and some considerable proportion of the charge is overburned and some underburned. In some kilns the bags, or vertical flues, in the interior of the furnace, are built up out of pieces of raw magnesite, which become strongly overburned and useless for cement making. It is, of course, usual to sort out the overburned material before grinding it, but this is not an easy matter, even to a highly experienced workman. The presence of overburned magnesite in a consignment cannot be detected by chemical analysis, and thus a material with quite a satisfactory chemical composition may be nearly useless for cement making.

The magnesium chloride used comes almost exclusively from the Stassfurt or Alsatian deposits, and is imported as the solid $MgCl_2 \cdot 6H_2O$, usually contained in thin iron drums. It is normally about 98 per cent. pure, but its quality can be easily determined by analysis.

Aqueous solutions having a specific gravity round about 22° Bé. are used for all ordinary purposes, and one of the drawbacks of the extended use of the cement is the cost of carriage and labour involved in the distribution of this solution, as it must be made at some convenient place in large dissolving tanks and distributed in drums to the actual work.

The various applications of this cement demand considerable experience and skill, and most operators

preserve a certain amount of secrecy about the exact details. As has been already stated, the most extensive use of the cement is for the making of floor compositions and the methods employed are all variations of the following process.

Ground calcined magnesite is mixed with hard-wood saw-dust in the proportion of 1 part of magnesite to $3\frac{1}{2}$ parts of saw-dust by volume. This mixture is gradually moistened with a magnesium chloride solution of about 22° Bé. until a portion squeezed in the hand adheres well together, but does not exude any moisture. The wet material is then spread evenly over the floor with a rake and carefully rammed down with a light wooden rammer. The surface is finally worked up with a steel float and the whole floor allowed two or three days to harden. If a coloured floor is required, the requisite amount of coloured earth (Indian red, burnt umber, or yellow ochre are commonly used) is added to the magnesite at the commencement of the operations.

In spite of the widespread use of this cement, there appears to be remarkably little known of the mechanism of setting, or of the factors which control it, and there are no published standards which enable the prospective purchaser of material to judge of its value. A very informative paper was read by Mr. M. Y. Seaton before the American Society for Testing Materials in June, 1921 (*Chem. and Met. Eng.*, August, 1921). The paper contains a great many useful suggestions and physical standards, but the author obviously labours under the difficulty of not being able to publish all he knows, particularly with reference to the effect of manufacturing conditions on the quality of the finished material. In spite of this fact, however, this paper contains more valuable information on the practical side of the question, than all the others which have been written. The difficulties in the way of obtaining accurate experimental data concerning the mechanism of setting are very great, and they will be best appreciated by considering the actual conditions which govern the practical application.

The concentration of the magnesium-chloride solution must be kept under careful control, as experience has shown that above a certain gravity, viz., 24° Bé., the setting cement will expand to such an extent as to destroy the shuttering or moulds, if it is being used "en masse," or to cause it to rise up in blisters if it is being laid as flooring. The setting time also is greatly accelerated as the concentration of the chloride increases, and the use of comparatively dilute solutions is necessary to ensure that the material can be properly worked before it hardens.

As previously stated, the usual strength is about 22° Bé., and with this concentration it is not possible to add sufficient actual magnesium chloride to combine with all the magnesia, without making the mass too wet to set at all; thus in a standard mixture containing 12·5 per cent. by volume of magnesia, the rest being an aggregate of coarse and fine sand, only about 50 per cent. of the chloride required to combine with all the magnesia is added, assuming, of course, that the compound $3\ MgO.\ Mg\ Cl_2.\ 10H_2O$ is actually formed. This means that a large proportion of the magnesia in a cement mixture merely acts as a filler and, as on account of its previous treatment, it can have very little structural strength, it detracts from, rather than adds to, the strength of the set cement. The apparently remarkable fact is therefore noticed with this cement, that test briquettes made of neat cement always show a lower tensile strength than briquettes made to the same consistency with cement and sand. Fig. 1 illustrates this very clearly. The continuous curve shows the variation in strength which takes place during a given period when a cement is prepared which contains 12·5 per cent. of

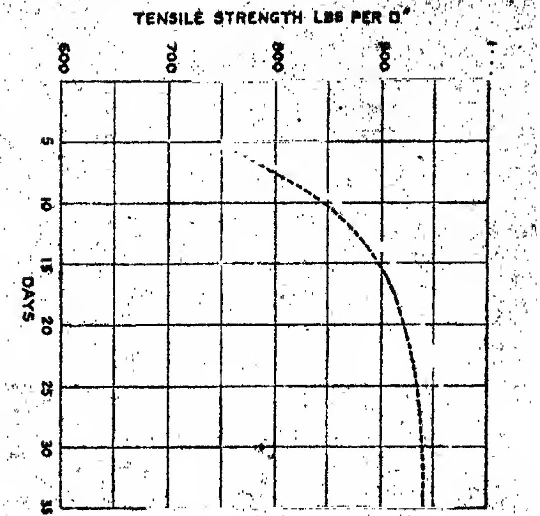

Fig. 1

magnesia by volume and 87·5 per cent. of siliceous aggregate. The dotted curve gives the strength of the cement made from pure magnesia only.

The expansion which takes place when the cement sets is a source of constant trouble to users of this material, particularly to floor layers, and as the amount increases with the strength of the chloride used, it must be obvious that a considerable volume change occurs in that portion of the material which is actually converted into magnesium oxychloride. Unfortunately, different samples of magnesite give widely different expansions on setting and there appears to be no observable reason for these differences so far as our present knowledge goes, except that a coarsely ground magnesite will produce a much greater expansion on setting than the same magnesite in a finely ground condition.

It is well known that when wetted throughout, a magnesite cement loses a great deal of its strength. In fact, a thoroughly soaked magnesite cement has practically no strength at all, and if left long enough in water will crumble away with the gradual dissociation of the magnesium oxychloride and the production of hydrochloric acid in the water.

The setting of the cement, therefore, depends to a very large extent on the rate of drying of the cement, and a fruitful cause of the lifting and cracking of flooring compositions is lack of ventilation, the air above the flooring becoming so saturated with moisture that drying practically ceases. Under these conditions the inevitable expansion which takes place in the cement when setting causes the floor to lift and crack in all directions, the material not attaining sufficient strength to prevent this from happening.

A floor which hardens normally must always contain a fair amount of internal stresses and cases are not unknown where the material has cracked and lifted, even after a lapse of years, consequent on the gradual weakening of the mass either through damp or excessive vibration. In the anxiety of the floor layer to prevent trespassers from spoiling his carefully trowelled surface he frequently closes all doors and windows in a completed room or passage, and thus invites the trouble he gets at a later stage.

It is easy to see that the mechanism of the setting of oxychloride cement is obscured by so many factors that exact knowledge is difficult of attainment, and a great deal of very necessary work remains to be done in order to ensure that this most valuable material shall give constant and reliable results.

It seems very likely that the actual cementing material exists in forms with widely differing degrees of hydration, and that the strength and degree of expansion of the set cement stands in close relationship to the aqueous content of these hydrates. Cylinders made some years ago of pure magnesite and magnesium chloride only, lost in weight regularly for the first fourteen days, and since then have been found to vary in weight constantly, being always heavier in damp weather than in dry weather. The variation is as much as 1 per cent. of the total weight of the cylinder.

It is probable, as in Portland cement, that the cementing material is the weakest portion of the set concrete, and hence the smaller the quantity which can be used the stronger and more permanent will the concrete be. Calcined magnesite itself is undesirable as one of the constituents of the aggregate as its particles have no physical strength, but other finely powdered materials which are not acted upon chemically by magnesium chloride, as for instance ground silica, will help to make a stronger and more resistant cement. The ideal cementing material in an oxychloride concrete is one in which the proportion of magnesite is made to correspond very closely to the theoretical amount of magnesium chloride required, the rest of the mass being siliceous or other neutral material at least as finely ground as the magnesite, and of course very thoroughly mixed with it. Thus, Seaton finds that if the cement be made from a mixture of 1 part of magnesite with 2 parts of fine silica, and the aggregate consist of standard sand, very strong concretes can be formed which do not contain more than 4 or 5 per cent. of magnesia.

As with Portland cement, the quality of the materials used must be as high as possible, and in order to ensure this, certain arbitrary limits indicating the physical and chemical properties must be laid down. In this country, unfortunately, little or no attempt is made by the user to buy his materials to specification, and this want of foresight is reflected in the large number of unsound jobs which are carried out.

TABLE I.

From article by M. Y. Seaton.

Magnesite No.	Chemical composition, per cent. Loss on Ignition	CO_2	SiO_2	R_2O_3	CaO	MgO	Cements made from 1 part magnesia, 2 parts ground silica and 5 parts sand; 22° Be chloride. Setting time in hours and minutes: Initial	Final	Modulus of rupture in lb. per sq. in.: Dry	Wet	Recovered
1	9·20	4·05	9·58	0·95	7·50	73·7	2 : 15	3 : 0	1500	828	1218

A chemical analysis of magnesite is useful in determining the probable source of the material and for making sure that it is free from adulterants; some typical compositions are given in Table I. Among some users, the belief is firmly fixed that the presence of lime as an impurity in calcined magnesia has a very deleterious effect on the strength of the cement, mainly due to the reaction of the lime with magnesia chloride which, as it does not result in a cementing material naturally weakens the finished product.

Messrs. Seaton, Hill and Stewart have written a long and informative article (*Chem. and Met. Eng.*, August 17, 1921) in which they give detailed results of their tests and indicate a satisfactory analytical method for determining the active lime present in a given sample. The results of their tests show that the most serious effect of the lime is in the reduction of the "wet strength" of the cement.

Experience has shown that the analysis alone is no guide to the behaviour of the material, much

more important factors being the rate and temperature of calcination, the age of the material, and the fineness of grinding. As the first two of these factors cannot be determined by either a physical or a chemical test it becomes necessary to rely on standard physical tests in order to gauge the suitability of the magnesite for cement making purposes.

Test briquettes can usefully be made in the same moulds as are used for testing Portland cement, the neat cement being made from magnesite and magnesium chloride only and the aggregate being made from Leighton Buzzard sand and ground silica which has passed a 120-mesh sieve. Seaton objects to the shape of these briquettes, as they are thicker than the material which is usually placed, when laying floors. He recommends long flat slabs ½ in. thick, made and dried on a sheet of oiled paper, in order to imitate as closely as possible the drying of an ordinary floor. The wet strength should be determined at the same time as the dry strength. Setting time can be determined by means of the Vicat needle, observing the same precautions as with Portland cement.

The expansion of the setting cement is of considerable importance, but, unfortunately, there is no standard method of determining it which gives satisfactory results. The best method is probably to lay a flat slab ½ in. thick on a piece of slightly greased plate glass and measure by suitable means the movement of two metal stops provided with "hair lines" and set about 8 in. apart. In order to put these suggestions on a proper footing the following tentative specification is given for a fine ground calcined magnesite to be used for laying floors :—

Fineness.—Eighty per cent. of the material should pass a 200-mesh screen and 99 per cent. should pass a 100-mesh screen.

Tensile Strength.—A mixture consisting of one part magnesite, two parts finely ground silica and five parts standard sand, should be used for these tests. The strength of the chloride solution should be 22° Bé. and the mixture should be just sufficiently wetted to allow of its proper working in the mould.

Standard briquettes of the type used in an ordinary cement testing machine are made and broken after 7 and 28 days, the test pieces being freely exposed to the air after taking out of the mould at the end of 48 hours. The moulds should be very slightly greased before use.

The average strength should be about 500 lb. per square inch at 7 days and about 850 lb. at 28 days.

Seaton recommends as previously explained a flat bar of concrete ½ in. thick, 2 in. wide and 24 in. long. These bars are supported at the ends for test purposes, and broken by loading the centre with shot in the same manner as in a cement testing machine. From this result the modulus of rupture is calculated and should be about 2·2 times the tensile strength given above.

Wet Strength.—The wet strength of set cement is important and should be determined by spraying the set briquettes with water three or four times during 8 hours and then testing in the usual manner. The wet strength of a good mortar should be not less than 30 per cent. of the strength of the dry mortar.

Setting Time.—The setting time of the same mixture as used above is determined in the ordinary way with a Vicat needle. The initial set should not take place before 90 minutes and the final set should be attained within 5 hours.

Expansion.—It was stated above that the exact causes of expansion are not thoroughly understood. In addition, occasional contractions in volume may take place in a setting cement, the causes of this phenomenon being also obscure. Undoubtedly too much liquid added to a cement will cause contraction just as it will with Portland cement, but there are certainly other factors at work. It may be taken, however, for all practical purposes that an expansion or contraction of 0·3 per cent. or over, within 24 hours after the initial set, indicates a cement of questionable quality.

CO-ORDINATION OF ORGANIC MOLECULES

By PROF. T. MARTIN LOWRY, F.R.S.

1. Organic Compounds of the Second Order

Werner's theory of co-ordination was developed in order to account for the existence of "molecular compounds," for which the ordinary laws of valency made no provision. This enterprise was remarkably successful in two branches of inorganic chemistry, namely, (i) those which deal with double salts, such as K_2PtCl_6, $K_3Co(NO_2)_6$ or $K_3Cr(C_2O_4)_3$, and (ii) those which deal with the addition of ammonia or of water to metallic salts, giving rise to amines or hydrates, such as $CrCl_3.6NH_3$, $CoCl_3.5NH_3.H_2O$, $NiCl_2.6NH_3$ or $NiCl_2.6H_2O$. Since these salts can include organic as well as inorganic radicals, whilst the ammonia of the amines can be replaced by organic nitrogenous bases, and the water of the hydrates by alcohols and ethers, Werner's theory acquired long ago a definite foothold in organic chemistry, and in recent years has extended its area of occupation considerably ; but even so, that area has been in the main confined to acid and basic radicals, which can play a part in the formation of those complex salts, with which Werner's theory was in the main concerned. On the other hand, it is becoming increasingly clear that organic chemistry includes a number of compounds of the second order, for the existence of which Werner himself had no clear explanation to offer, but which demand recognition just as definitely as the double-salts and hydrates of inorganic chemistry.

2. Addition-compounds of Alcohols, Ethers, Ketones and Esters

Just as in the case of inorganic molecular-compounds, many addition-products formed by organic compounds can be represented by means of formulæ which conform to the ordinary rules of valency, although it is by no means certain that such formulæ are always correct. Thus the addition-compounds of alcohols and ethers with acids[1], such as

$CH_3.OH,HBr$ $C_2H_5.OH,HBr$

$(CH_3)_2O,HCl$ $(CH_3)_2O,HBr$ $(CH_3)_2O,HI$

can be represented as oxonium salts, containing a quadrivalent atom of oxygen as the centre of the complex; and the opening out of a double bond will supply points of attachment for the acid in the analogous addition-compounds of acetone and of ethyl acetate[1], such as

$COMe_2,HBr$ and $CH_3.CO_2Et,HBr$.

But even in these cases it is disconcerting to have to recognise the existence of compounds such as

$(CH_3)_2O,3HCl$ and $(CH_3)_2O,4HCl$

or $2CH_3.CO_2Et,5HBr$ and $CH_3.CO_2Et,4HBr$.

Again, by subjecting the idea of salt-formation to a somewhat severe strain, and also taking into account the amphoteric character of the halogens, for which a considerable amount of evidence has now been accumulated[2], it is possible to formulate in a similar way the less stable compounds formed by the union of alcohols, ether, ketones and esters with the halogens[3], *e.g.*,

$2CH_3.OH,Br_2$ and $2C_2H_5.OH,Br_2$

$COMe_2,Cl_2$ and $COMe_2,Br_2$;

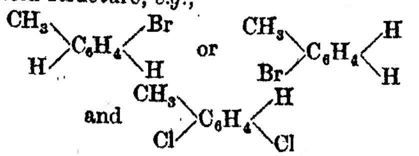
but, again, it is necessary to allow for the existence of more complex compounds, such as

$2CH_3.CO_2Et,3Cl_2$ and $2CH_3.CO_2Et,3Br_2$.

This method of formulation breaks down, however, in the analogous addition-compounds of toluene, such as

$C_6H_5.CH_3,HBr$ and $C_6H_5.CH_3,Cl_2$;

and in order that the ordinary rules of valency may be maintained these must be shown as possessing a quinonoid structure, *e.g.*,



3. Complexes Formed by the Union of Two Organic Molecules

The devices suggested above serve to explain the formation of addition-products by the union of organic compounds with simple inorganic substances; but they fail to account for most of the addition-products that are formed by the union of two organic compounds with one another, and it is difficult to see how they can be extended to cover all the compounds set out below, *e.g.*,

(*a*) Bimolecular acetic acid $(C_2H_4O_2)_2$.

(*b*) Camphoric acid and acetone $2C_8H_{14}(CO_2H)_2$, $COMe_2$[4].

(*c*) Picrates of hydrocarbons such as naphthalene, anthracene, phenanthrene and fluorene, *e.g.*, $C_{10}H_8$, $C_6H_2(NO_2)_3OH$.

(*d*) The addition-compounds of aromatic amines, such as α and β naphthylamine, with trinitro-derivatives of benzene, studied by Sudborough[5], as well as the analogous compounds of phenols, phenolic esters and cyclic oxygen-compounds with aromatic polynitro-compounds.

(*e*) The addition-compounds of complex aromatic hydrocarbons (or their halogen-derivatives) with CCl_4, $CHCl_3$, CBr_4, $CHBr_3$, SO_2Cl_2, $COMe_2$, $COMeEt$[6].

The addition-products studied by Norris under the last heading include the following compounds:—

(*a*) $(C_6H_5)_2CCl.CCl(C_6H_5)_2$ M.p. 160–161°

+ $2CHCl_3$	Quickly becomes cloudy and opaque; melts at 134–135° C. with decomposition.
+ $2CCl_4$	Decomposed in two months in a vacuum desiccator; in four days at 90–100°. Melts at 178–9°.
+ $2CHBr_3$	Crystals were dried in air and analysed by heating to 92°.
+ $2CBr_4$	Crystallised from CS_2; analysed by heating at 92° for 38 hours; melts at 144–147°.
+ $2CHBrCl_2$	Completely decomposed in 1 hour at 92°.
+ $2SO_2Cl_2$	Unstable in air; decomposed by recrystallising from acetone; effloresces rapidly.

(*b*)  M.p. 135–137°.

+ $CHCl_3$	Melts at 58–59°, loses $CHCl_3$ rapidly in air.
+ $2CCl_4$	Melts at 91–92°, decomposed very quickly.

(*c*) 
No addition-compounds formed with the above agents.

(*d*) 
+ $3COMe_2$	Crystals become opaque in air.
+ $COMeEt$	Much more stable.
+ $COEt_2$	Stability not stated.
+ CCl_4	Effloresces rapidly.
+ CH_3CO_2Et	Relatively stable. Lost 0·1 per cent. in 10 minutes.
+ C_6H_6	Stability not stated.

(*e*) $4(C_6H_5)_3COH + 3CCl_4$	Effloresces rapidly.
$(C_6H_5)_3COH + 2COMe_2$	Effloresces slowly.
$2(C_6H_5)_3CCl + COMe_2$	Product relatively stable
$(C_6H_5)_3CCl + CCl_4$	Does not effloresce rapidly.
$(C_6H_5)_3CH + C_6H_6$

4. Aggregation of Molecules in Crystals

It will be seen that the compounds formulated above contain only carbon, hydrogen, oxygen and halogens; they do not lend themselves, therefore, at all readily to the ordinary form of centric co-ordination, since none of these elements possesses any very conspicuous powers of aggregation. It is, of course, by no means certain that it is necessary in every case to postulate the existence of a definite co-ordination, by means of localised linkages, between the constituent molecules of an addition-compound, in view of the possibility that molecules of "solute of crystallisation" may be used merely to fill up hollows in the open lattice of the crystals of an organic compound. Thus, even in inorganic chemistry, zeolites can be dehydrated without destroying the structure of the crystals, of which the transparency can be restored, and the original optical properties reproduced, by exposing once more to the access of moisture. Again, the proportions of water of crystallisation that separate with typical co-ordination-compounds are so variable that Werner was, as a rule, obliged practically to ignore all those molecules of water that are not obviously included in the primary sphere of co-ordination of the central atom of the complex; thus, after tabulating the number of molecular proportions of water in 81 double oxalates[7] he does not even hint at the existence of any rules by which these proportions can be predicted.

The case of the optically-active oxalates[8] is particularly interesting, since the d and l salts of the composition

$$K_3[Co(C_2O_4)_3] + H_2O$$
$$K_3[Rh(C_2O_4)_3] + H_2O$$
$$K_3[Ir(C_2O_4)_3] + H_2O$$

yield racemates of the composition

$$2K_3[Co(C_2O_4)_3] + 7H_2O$$
$$2K_3[Rh(C_2O_4)_3] + 9H_2O$$
$$2K_3[Ir(C_2O_4)_3] + 9H_2O$$

In these cases it can scarcely be supposed that the optically-active ions of the d and l salts and of the racemic d and l mixture are differently hydrated in solution. The different composition of the crystals is clearly due to the fact that, when ions of uniform sign are assembled, there is only room in the interstices of the complex oxalate-ions for one molecular proportion of water, together with the three potassium ions shown in the formula of the salt; but when the d and l ions of the racemic compound are assembled, in pairs of ions of opposite sign, each pair can make room for 5 or 7 additional molecules of water, giving the totals of 7 or 9 H_2O set out above. Even in cases such as these, however, chemists will be reluctant to admit that the formation of addition-compounds, of exact stoichiometrical composition, are dependent only on the filling up of molecular ca[illegible] and will in general seek to detect the existe[illegible] definite chemical forces between the molecule[illegible] united, even when the points at which these [illegible] act must be ascertained by crystallographic [illegible]er than by purely chemical methods.

5. The Cementing Power of Electrons and of Protons

Physicists have postulated, and chemists have concurred in the view, that electrons provide the cement by which atomic nuclei are united to one another. Physicists have even gone further, and suggested that, in an α-particle or helium-nucleus four protons are held together by their mutual attraction for two nuclear electrons, and, indeed, are held so strongly that the union, if represented as an exothermic chemical action, would correspond to a "heat of reaction" of 6,000,000,000,000 calories.[9] In these circumstances it was almost inevitable that it should be recognised, sooner or later, that the reciprocal action of protons in attracting electrons must play a special part in chemistry, in view of the fact that the proton, like the α-particle, has no surrounding shell of electrons to help it to curb its attraction for electrons belonging to other atoms.

The entirely heterodox idea that hydrogen (the strict univalency of which has generally been regarded as above suspicion) can act as a link between two other atoms was foreshadowed by Werner, but has recently been put forward as a definite hypothesis, under the title of "Co-ordinated Hydrogen,"[10] or "Bivalent hydrogen."[11]

The ability of a proton to link together two complete octets of electrons is seen most clearly: (i) in the complex anion of the acid fluorides, which Werner wrote as (F.HF), but which may now be formulated symmetrically as $[\overset{-}{F}\overset{+}{H}\overset{-}{F}]$, (ii) in the polymerisation of water, and (iii) in the formation of crystals of ice, which are represented by Bragg as being built up in the form of a lattice containing a repeating pattern of the type

$$\begin{array}{ccccccc}
 & :\ddot{O}: & & :\ddot{O}: & & & \\
 & \mathrm{H} & & \mathrm{H} & & & \\
H & :\ddot{\mathrm{O}}: & \mathrm{H} & :\ddot{\mathrm{O}}: & \mathrm{H} & :O: & \\
 & H & & H & & &
\end{array}$$

This conception was applied by Burgess and myself mainly to organic molecules, in which the closing of a ring by a "[illegible]" (as Lewis calls it) or co-ordinated hydrogen [illegible] can be used to explain the absence of free rotation and other related phenomena. Lewis' applications are mainly in the field of inorganic chemistry, and include the suggestion that this novel type of linkage may be present in compounds such as ammonium hydroxide, which may have the electronic structure

$$\begin{array}{c}
\mathrm{H} \\
\mathrm{H}:\ddot{\underset{..}{\mathrm{N}}}:\mathrm{H}:\ddot{\underset{..}{\mathrm{O}}}:\mathrm{H} \\
\mathrm{H}
\end{array}$$

[9] Sommerfeld, *Atomic Structure*, p. 95.
[10] Lowry and Burgess, *Trans. Chem. Soc.*, 1923, **123**, 2111.
[11] Lewis, *Valence*, 1923, p. 109.

instead of the ionised structure shown in the formula

$$\begin{array}{c}\mathrm{H}\\ \mathrm{H:\ddot{N}:H}\\ \mathrm{H}\end{array}\ \text{plus}\ \mathrm{:\ddot{O}:H}\ \text{or}\ \overset{+}{\mathrm{N}}\mathrm{H_4}\ \text{plus}\ \bar{\mathrm{O}}\mathrm{H}$$

This representation is attractive in that it indicates at once the probable formation of the more symmetrical addition-compound $(NH_3)_2H_2O$ or $(NH_4)_2O$; which can be formulated as

$$\begin{array}{ccccccccc} & & \mathrm{H} & & & & \mathrm{H} & & \\ \mathrm{H} & : & \mathrm{N} & : & \mathrm{H:\ddot{O}:H} & : & \mathrm{N} & : & \mathrm{H} \\ & & \mathrm{H} & & & & \mathrm{H} & & \end{array}$$

instead of as

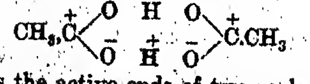
$$2\begin{array}{c}\mathrm{H}\\ \mathrm{H:\ddot{N}:H}\\ \mathrm{H}\end{array}\ \text{plus}\ \mathrm{:\ddot{O}:}\ \text{or}\ 2\overset{+}{\mathrm{N}}\mathrm{H_4}\ \text{plus}\ \overset{=}{\mathrm{O}}$$

In general, the formation of complexes of this type depends on the fact that a proton can be attracted simultaneously by duplets belonging to the octets or outer electron-shells of *two* other atoms or ions; but it appears also to be essential that the proton should not be embedded too deeply in the electronic system of either atom. In other words, a hydrogen atom which is to act as a link between two atoms must be capable of being detached from either of them, in the form of a "mobile hydrogen atom" or hydrogen ion, or in combination with some other atom.

6. Co-ordination of Hydrogen with Halogens and With Oxygen, as an Aid to the Formation of Molecular Compounds

Whilst it would be premature to attempt to assign definite co-ordination-formulæ to all the addition compounds set out in Section 3 above, it is suggested that the co-ordination of hydrogen with halogens, or with oxygen, may provide a key to the origin and general character of the force which holds many of these organic complexes together.

(*a*) Lewis has already suggested that the formation of double molecules of acetic acid can be interpreted by a locking together of two carboxyl-groups, such as I have postulated as an explanation of the absence of free rotation in certain dicarboxylic acids.[12] This view can be expressed by a formula of the type



which shows the active ends of two molecules interlocked, leaving the inert hydrocarbon radicals on the outside, as in the films of fatty acids recently examined by Müller and Shearer.[13]

(*b*) Norris points out that the formation of addition-compounds is apparently related to reactivity in one or both of the component molecules. In this respect he lays special stress on the mobility of chlorine and hydroxyl in $(C_6H_5)_3CCl$ and $(C_6H_5)_3COH$, as well as of the hydrogen in triphenylmethane, $(C_6H_5)_3CH$. He also refers to the reactivity of the halogen in the dichloride of tetraphenylethylene, as indicated, for instance, by the fact that the hydrocarbon will not form a dibromide. Reactivity can also be ascribed to the halogens, not only in sulphuryl chloride, SO_2Cl_2, but also in compounds such as carbon tetrachloride and chloroform, both of which can be converted without difficulty into the still more reactive carbonyl chloride $COCl_2$.

(*c*) In the same way, attention may be directed to the presence of reactive atoms of hydrogen in one component of many of these complexes. This does not need stressing in the case of the carboxylic acids; but it is not unreasonable to think that the usefulness of acetone and ethyl acetate in forming addition-compounds may depend, not so much on the direct influence of the oxygen which they contain, as on the reactivity of the hydrogen atoms in these compounds. The *para* hydrogen atom of the phenyl group is also reactive, and easily displaced by halogens; and it is noteworthy that the hydrocarbons which form picrates are also more reactive than benzene, behaving in this respect rather like substitution-products of this hydrocarbon.

(*d*) It is suggested that the attraction of a proton for a "lone pair" of electrons on nitrogen, oxygen or a halogen (it cannot find one on carbon, *e.g.*, in methane) may be responsible for the co-ordination of many of the compounds now under discussion, and that this attraction is perhaps strongest between halogen-atoms which are readily replaced by hydrogen, and hydrogen-atoms which are readily replaced by halogens. This view of the origin of the attraction is supported by the fact that, in Norris' compounds, substitution of all the *para*-hydrogens by a halogen prevents almost completely the formation of addition-products with CCl_4, CBr_4, etc., whilst the substitution of only one hydrogen already makes the addition-products much less stable. On the other hand, this substitution appears to promote the formation of addition-products with $CO(CH_3)_2$, etc. The principal exceptions to this classification are a very unstable addition-compound of $(BrC_6H_4)_2C{:}C(C_6H_4Br)_2$ with CCl_4, and an addition-compound of triphenylmethane with benzene which contains neither oxygen nor a halogen.

In conclusion, it is not claimed that a clear statement can yet be made as to the mechanism by which organic compounds are united into dissociable addition-products. The object of this paper is rather to direct attention to the problems which are presented by this class of compounds, and to suggest lines along which a solution of this problem may be sought.

7. Summary

(*a*) Attention is directed to the existence of molecular-compounds formed by the union of organic molecules, and to the difficulty of assigning definite co-ordination-formulæ to them, in view of the fact that many of them contain only carbon, hydrogen, and oxygen or a halogen.

(*b*) It is suggested that the co-ordination with chlorine or oxygen of a hydrogen atom already attached to another atom of oxygen or to carbon affords a possible explanation of the linking together of molecules of this kind.

THE NEWER ELECTROCHEMICAL VIEW OF THE CORROSION OF METALS

By ULICK R. EVANS, M.A.

At one time the corrosion of metals was regarded as due to a simple chemical attack by oxygen and water, possibly with the co-operation of other substances, such as carbonic acid or hydrogen peroxide. The capricious and often local nature of the attack has, however, suggested that the mechanism may be more complicated, and recent research has afforded an insight into the nature of that mechanism.

As a matter of fact, the simple oxidation of metals in the manner suggested above can actually take

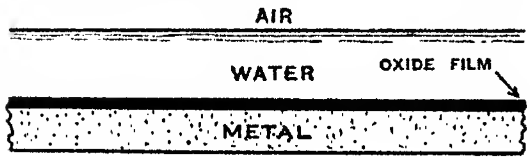

Fig. 1

place, but, through its very nature, it is unlikely to cause much damage to a metallic article. Consider (Fig. 1) a piece of metal immersed horizontally beneath a shallow layer of water. If the metal is perfectly uniform (both chemically and physically), and if the oxygen diffusing from the air through the water has equal access to all parts of the surface, then it would seem probable that the formation of oxide or hydroxide would go on equally all over the surface; and since the oxide will be formed *in situ*, we should expect to get an adherent layer of oxide all over the metallic surface. This will clearly hinder the continuance of attack upon the underlying metal. It seems possible that if the condition of absolute uniformity postulated above could be realised, the film would, in many cases, become perfectly protective, before ever it reached visible thickness.

If, however, the uniformity either of the metal, or of the oxygen-supply, is not perfect, the result may be different. Let us first take an extreme case, and imagine (Fig. 2) an article, one end of which is composed of zinc and the other of copper; suppose it to be immersed in water containing traces of a soluble salt, say, sodium chloride or calcium sulphate, salts which occur in most samples of ordinary water. As is well known, an electric current will be set up, the zinc being the anode and the copper the cathode. At the zinc surface, a soluble zinc salt (chloride or sulphate) will be formed, whilst hydrogen ions will be discharged upon the copper, the hydrogen being destroyed, as it is produced, by the dissolved oxygen; the rate of corrosion is indeed controlled by the supply of oxygen to the surface. This destruction of hydrogen ions from the copper surface leaves the water alkaline along that surface. The zinc salt and the alkali (sodium or calcium hydroxide) diffuse together, and near the junction of the zinc and copper a precipitate or membrane of insoluble zinc hydroxide will appear. Since this hydroxide does not coat the main portion of the zinc surface, it will not interfere with the subsequent course of corrosion.

It might easily be imagined that a similar electrochemical action would be set up in alloys, or even impure metals having a duplex structure. But it must be remembered that most alloys do not consist simply of a mosaic of the pure component metals. The brasses, for instance, consist not of a mosaic of copper and zinc, but of one or more solid solutions containing both metals; the commonly employed brass containing 70 per cent. of copper consists of a single solid solution, and may be just as homogeneous as a piece of pure copper. There is no reason to expect corrosion-couples to be set up in such a material more easily than in the pure metal.

Even if we consider a hypothetical alloy consisting of a mosaic of the two constituent metals, it is unlikely that we shall get very rapid corrosion. No doubt at first, on the immersion of such an alloy in saline water, we shall get a soluble salt produced upon the particles of the anode-metal and alkali produced upon the particles of the cathode-metal. These products will interact to form the insoluble hydroxide, but, since this will be formed very close to the metal surface, it will almost certainly tend to "blanket" the surface, and so retard further corrosion. Of course, it will not be so perfectly protective as the oxide-film formed *in situ* by direct oxidation; indeed, under some conditions it may be loose enough to permit corrosion to proceed at an appreciable rate; the corrosion-product seems to be least protective if produced in the presence of chlorides. But in general, *if the blanket is formed all over the surface*, it will tend to retard corrosion as it becomes thicker. Furthermore, if the alkali from the cathode-metal should gain access to the surface of the anode-metal, we may get an insoluble hydroxide as the direct anodic product, and this body being formed *in situ* will efficiently protect the underlying metal and interfere with further electrochemical action.

We see, therefore, that whereas *duplex structure on a coarse scale* (*e.g.*, in an article composed of one metal at one end and a second metal at the other) is apt to stimulate corrosion very considerably, *duplex structure on a fine scale* (*e.g.*, in a heterogeneous

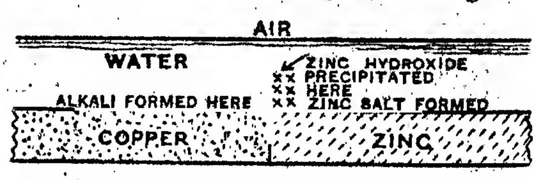

Fig. 2

alloy) is much less dangerous. This is well shown by an example described by Murray[1], who studied the rusting of "double-faggoted" iron (consisting of alternate layers of wrought iron and mild steel). He found that this material rusted more readily than ordinary steel, and that the rusting took place at the junction between the layers of wrought iron

[1] M. T. Murray, *J. Chem. Met. Min. Soc. S. Africa*, 10

and steel. Microscopic observation, however, showed no special corrosion at the junction of the ferrite and pearlite areas within the steel.

The danger of having two dissimilar metals in contact (except in certain cases) is so well known that examples of corrosion due to this cause are now met with comparatively seldom, although one still hears of trouble caused at soldered joints. There is, however, a possibility of obtaining cathodic and anodic areas on a coarse scale in another way, which is not generally appreciated. I have shown[2] experimentally that it is possible to produce an electric current from a cell consisting of two strips of the same metal immersed in the same solution, one strip being aerated by bubbling air over it, whilst the other is protected from access of oxygen; the current is provided by the corrosion of the *unaerated* metal, and, if the resistance of the whole circuit is small, the unaerated strip actually suffers more corrosion than the aerated strip. This production of current by "differential aeration" can be shown in zinc,

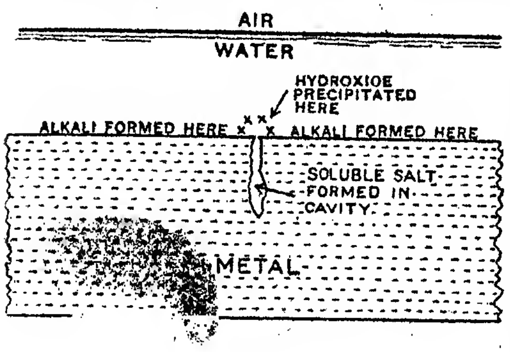

Fig. 3

cadmium, iron and lead; in copper other factors come in which tend to mask or even prevent the current. In the case of articles made of zinc, iron and lead, however, currents of this kind seem to be responsible for practically the whole of the corrosion observed when they are exposed unequally to the action of oxygen; for instance, when they are partly immersed in water, or covered with drops of water over part of their surface. It also accounts for the special corrosion set up in cavities. Suppose (Fig. 3) that a small cavity exists in the surface of the metal into which oxygen cannot diffuse quickly. A current will be produced between the unaerated area within the cavity, which will become anodic, and the aerated part of the surface outside, which will be the cathode; soluble salt will be formed at the anodic surface within the cavity, but this will not, of course, interfere with further anodic attack. At the mouth of the cavity where the soluble metallic salt from the interior mixes with the alkali from the cathodic part outside, hydroxide may be precipitated, but it will not put a stop to the anodic attack proceeding within. Since the rate of attack is determined by the supply of oxygen to the whole surface outside the pit, and since it is all concentrated on the small area within the pit, the rate at which the corrosion bores into the metal will be very great; and perforation of the article may occur at this one point before any appreciable thinning has occurred at other parts of the surface. Thus we get an explanation of *pitting*.

A similar explanation serves to interpret the special corrosion which occurs at parts of the surface covered up by sand or other debris. The part below the debris is protected from oxygen and therefore becomes anodic. The same reasoning serves to show why rust (if of a loose, flocculent character) tends to promote further corrosion of the underlying metal; this explanation, which was first given by J. Aston[3], is undoubtedly the correct one; there is no need to assume that the iron hydroxide (colloidal or otherwise) serves as a catalyst.

The description just given may serve to convey a brief idea of the *newer electrochemical theory of corrosion*. It rests upon a clear experimental demonstration of the current passing between the aerated and unaerated parts of a metallic article, and has an interest for the practical man which the older theories have never had, because it is able to explain the phenomenon of pitting and local corrosion at inaccessible places—the types of corrosion which cause most anxiety in practice; the chemical theories and even the older electrochemical theory of Whitney failed to account for this specially rapid corrosion observed *at just the points which were the least accessible to oxygen*. The distinctive feature of the newer theory is that it takes account, not merely of currents set up by contact between dissimilar metals, but also of those set up through unequal distribution of dissolved oxygen. We are thus led to the practical conclusion that contact with porous non-conductors may be just as dangerous in setting up corrosion as contact with a second metal.

Although in the majority of instances, the direct action of oxygen on metals does not lead to appreciable destruction of the parts so affected, owing to the protective character of the product, there are conditions under which direct chemical (as opposed to electrochemical) corrosion may occur quite rapidly. The dissolution of metals by oxidising acids, for instance, may consist in part of a direct oxidation of the metal, the oxide-film being dissolved away as quickly as it is formed. The action of hot cupric chloride solution on copper also seems to be a case of direct chemical action; the product, cuprous chloride, although insoluble, is non-adherent, and does not protect the copper.

PULVERISED FUEL FIRING IN COMBINATION WITH MECHANICAL STOKING

(From a Correspondent)

Considering the controversy as to the advantages and disadvantages of pulverised fuel firing for steam generation, the ordinary industrial steam user is perhaps more particularly interested in the matter from the point of view of his own individual conditions. It is admitted that for large water-tube boilers with the proper setting, and particularly the correct volume of combustion chamber, pulverised fuel gives results approached by no other method of firing solid fuels, *i.e.*, sustained efficiencies of 85–88 per cent., with only 15–25 per cent. excess air over the theoretical according to the rating of the boiler.

What the chemical works manager or engineer wants to know, however, is how can the advantages of pulverised fuel be obtained with "Lancashire," or ordinary water-tube boilers and the existing setting. It is thus of interest to note that Dr. Lulofs, the chief engineer of the Amsterdam Electricity Works, has combined the use of pulverised fuel firing with that of the ordinary chain-grate or similar travelling-grate mechanical stoker. The method consists in the installation of a number of small pulveriser fuel burners supplied by a unit pulveriser at the back of the stoker so that the pulverised fuel flame is almost parallel with the chain-grate pointing slightly inwards and at right angles to the mechanical stoker flames. The arrangement, the patent rights of which are controlled by the Underfeed Stoker Co., Ltd., is said to have a number of advantages, particularly that the chief defect of the chain-grate stoker, the hollow fires at the back with consequent excess of air, is obviated. This is very efficient, giving 13–14 per cent. of carbon dioxide, instead of the 5–6 per cent. usual with chain-grate stokers. In working, the unit pulveriser is adjusted so that a reduced amount of air is mixed with the pulverised coal in the machine, so as to use up the excess of air due to the inefficiency of the mechanical stoker in burning the pulverised coal. The results are stated to be of particular value in peaked load periods, the flexibility of pulverised fuel being of great assistance in this respect and in that of reducing stand-by losses in starting up and shutting down. This method therefore enables steam users possessing a chain-grate or other travelling grate stoker considerably to increase the efficiency of the existing boiler plant by taking advantage to a partial extent of the very high efficiency and flexibility of pulverised coal without any alteration to the setting of the boilers and the size of the combustion chamber and at only a small capital cost for a unit type of pulveriser.

According to the *Manchester Guardian* the firm of Brunner, Mond and Co., Ltd., has given £300 to the Department of Physics of Manchester University in aid of research.

The Physical Society of London is arranging to celebrate its jubilee from March 20 to 22 next. The preliminary programme of the proceedings will be as follows: On Thursday, March 20, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 2.30 p.m., there will be an Exhibition of Apparatus, followed by a reception at 3.0 p.m., and at 3.45 the Guthrie Lecture on "Photo-electric Effects in the case of High Frequency and Allied Phenomena" will be delivered by M. le Duc de Broglie. On Friday, March 21, from 4.0 to 5.30 p.m., and from 6.0 to 7.30 p.m., reminiscences by Original Fellows and other Fellows of long standing will be given, and on Saturday, March 22, there will be a continuation of the Exhibition, and at 7.0 p.m. for 7.30 a banquet will be held for Fellows and guests only.

The Council of the Physical Society extends to the members of this Society a hearty invitation to be present at these meetings, and, according to present arrangements, no tickets will be required for this purpose.

SOCIETY OF CHEMICAL INDUSTRY

LIVERPOOL AND MANCHESTER SECTIONS

A joint meeting of the above Sections was held in Liverpool, on February 22, Mr. Edwin Thompson in the chair. Those present included Dr. E. F. Armstrong, F.R.S., President of the Society, Dr. H. Levinstein, Chairman of the Manchester Section, Mr. L. Guy Radcliffe, Hon. Secretary of the Manchester Section and about 100 members of the two Sections. A paper was read by Professor I. M. Heilbron on "Plant Pigments."

Professor Heilbron commenced by pointing out that the pigments of nature may be divided broadly into two classes, on the one hand the plastid pigments—chlorophyll and the carotinoids—and on the other, soluble sap pigments of which many well-defined groups are known, notably the yellow-coloured flavonols and the highly-coloured anthocyans. Dealing with chlorophyll, the lecturer explained its occurrence in the chloroplasts and broadly discussed the constitution of the pigment. An examination of chlorophyll was undertaken by Berzelius as early as 1838, but until 1906, when Willstätter began his investigations, our knowledge regarding the constitution of the pigment was extremely meagre. An explanation was then given of the methods employed by Willstätter in attacking the problem, and the lecturer showed how the purely chemical evidence arrived at clearly indicated the presence of two chlorophyll components in the green leaf. Complete justification for these views was reached by Willstätter's isolation of the pigment in the solid state and its subsequent separation into its two components: chlorophyll "a" and chlorophyll "b."

A brief account was next given of the carotinoid pigments and it was pointed out that these were common to both the plant and animal kingdoms. The occurrence and properties of various carotinoids were described and specimens of pure carotin and xanthophyll exhibited. A brief discussion of the part played by chlorophyll in the life-processes of the plant followed and experimental evidence was given in support of the hypothesis (*cf.* Baly and Heilbron, *J.S.C.I.*, 1921, 40, 277 R) that carotin and xanthophyll actually play a part in the photosynthetic process. The soluble sap pigments were also considered and the close relationship existing between flavones, flavonols and anthocyans discussed. Professor Heilbron illustrated by direct experiment the ease with which ring closure and the formation of the strongly-coloured pyrylium nucleus could be induced by the action of mineral acids on *o*-hydroxy cumar ketones, and showed the important bearing of the position of the hydroxyl groups in the molecule on the colour of the compounds formed.

In the afternoon a party of about 70 was conducted through the works of Messrs. Johnson Brothers (Dyers) Ltd., Bootle, by the kind invitation of the directors, who also provided the visitors with tea. The day's proceedings ended with an informal dinner at the

NOTTINGHAM SECTION

At a meeting on February 20 two papers were read by Mr. S. R. Trotman, M.A., and Mr. R. W. Sutton, B.Sc :—

I. "A Note on the Estimation of Poisonous Metals in Gelatin for the U.S.A. Food Laws." There is no limit in the United Kingdom for the impurities present in gelatin such as arsenic, sulphur dioxide, lead, copper and zinc, but in the United States and other countries gelatin for food purposes has to conform to certain standards. The authors, who have had a large experience in estimating small amounts of these impurities, gave brief details of various methods. Estimations of arsenic by standard mirrors, lead and copper colorimetrically and zinc gravimetrically as oxide (finally), gave accurate results even when present in very small quantities. Sulphur dioxide is best determined by distillation (steam) into bromine water and weighing as sulphate.

II. "The Weathering of Cotton and Wool with Special Reference to the Action of Bacteria." One of the chief properties of any textile fibre is its permanence in air under ordinary conditions. The term "weathering" is applied to the factor which causes gradual disintegration—apart from the strains and stresses of ordinary wear—and the power of resistance to weathering is lessened by faulty physical and chemical processes in the preparation of the material.

In general the two chief causes of the deterioration of textile fabrics appears to be actinic light and atmospheric oxygen. Actinic light, together with traces of ozone, brings about deterioration of wool Cotton is affected chiefly by actinic light, although traces of ozone (especially in presence of water) act as a contributory cause of deterioration.

The action of bacteria as a cause of weathering has received much less attention than the other causes and experiments were described showing the importance of the presence of micro-organisms—especially *B. subtilis* and *B. mesentericus*. Cotton fibre attacked by *B. subtilis* first swelled up, lost its natural twist, and in some places globular swellings caused rupture of the cuticle, the latter being completely destroyed in 48 hours. During a period of seven days it was noted that at first that an increase in tensile strength occurred, followed by a decrease (after three days), and this decrease was found to correspond with an increased number of globular swellings. The nitrogen content of the cotton suffered very little diminution during the experiments, so that the removal of proteins could not be effected by the action of *B. subtilis*; neither was the removal of starch as rapid as by the action of diastase. The action of *B. mesentericus* gave similar results, although the action was less marked. Wool attacked in a similar way soon became rotten, and showed a greater affinity for acid and basic dyes.

In the discussion, Mr. Pentecost inquired whether hydrogen peroxide would not be better than sulphur dioxide for bleaching and preserving gelatin to be used for food purposes. Would the cause of the rotting of garments found in the tomb of Tut-ankh-Amen be due to the action of micro-organisms? Dr. Prideaux referred to some of the points dealt with in analytical work, and asked what was the cause of the globular swellings in cotton produced by *B. subtilis*? Mr. Burford asked as to the fate of the bacteria which brought about deterioration of fabrics. Mr. Heyes mentioned that recent researches gave results in close agreement with those of Mr. Trotman; the action of bacteria on wool was greatly increased by alkalinity. Mr. Barber inquired as to the best method for sterilising wool and cotton.

In reply, Mr. Trotman said that hydrogen peroxide was not used as a preservative or bleaching agent for gelatin because sulphur was cheaper, and hydrogen peroxide in alkaline solution would hydrolyse the gelatin. If used in acid solution the peroxide would not bleach, and, further, the gelatin would act as a protective colloid, and subsequent decomposition of the peroxide with liberation of oxygen would give the gelatin a bubbly appearance. The swelling of cotton cuticle was due to the cotton assuming a true colloidal condition. Bacteria would grow in a medium until they produced enough toxin to kill. The p_H value was an important determining factor for the type of bacteria which will grow in a medium. Cotton was best sterilised by boiling, wool by keeping in contact with chloroform. The disintegration of fabrics in the tomb at Luxor was certainly due to bacteria, as no actinic light could have gained access.

SOUTH WALES SECTION

On February 8, at the Technical College, Cardiff, Mr. H. W. Webb, M.Sc., opened a discussion on the action of acids on metals, Mr. W. R. Bird being in the chair.

Mr. Webb dealt exclusively with the acids hydrochloric, nitric and sulphuric in their action on iron, lead and copper. The sources of error in laboratory tests were mentioned, points such as the influence of impurities in the acids, change in concentration of acids during test, aeration, surface, homogenity of metal, etc., being dealt with. The influence of arsenic in the sulphuric acid used for pickling, of the nitrous acid in nitric acid, and of aeration in the solution of copper in acids were each discussed. Acid attack on metals was shown to be divisible into two classes: (*a*) Those in which hydrogen evolution occurs, and (*b*) Oxidation reactions. Sulphuric acid belongs apparently to both classes, since at low temperatures the gas evolved by a solution of a metal such as iron is mainly hydrogen, irrespective of the concentration of the acid, while at high temperatures the gas is exclusively sulphur dioxide. The influence of impurities in lead on the rate of attack by sulphuric acid was also treated in detail, and it was shown that small percentages of copper (0·1—0·75 per cent.) increase the resistance of the lead at high temperatures, whereas at ordinary temperatures pure lead was more resistant than lead containing antimony (hard lead), or regulus. The temperature at which gas evolution commences was not considered to be the best criterion of rate of attack. Mr. Webb concluded by referring to the

use of iron-silicon alloys in acid plant, and reviewed their intrinsic difficulties and the present position in chemical industry of such acid resisting alloys.

A very interesting discussion ensued. Mr. W. R. Bird dealt with the value of nickel and chromium steels for resisting acids, and mentioned some of the difficulties connected with iron-silicon alloys. Mr. Clegg gave an account of his experience in the use of antimony pumps for hydrochloric acid, and mentioned the importance of temperature in this respect. Prof. Edwards (Swansea) pointed out that, as regards the action of acids on alloys, the addition of a metal B to a metal A, in general, gave a product more resistant to acids, and that the continued addition of B increased this resistance to attack until the eutectic composition had been passed, when further addition of B accelerated the rate of attack by galvanic action. Prof. Edwards also described some very interesting work he had carried out on the passage of hydrogen through metals. Mr. J. R. Green stated that pure tin is more rapidly soluble in hydrochloric acid than tin containing small quantities of impurities, such as lead and iron. Mr. Rudge described the importance of aeration in the parting of copper-gold alloys by sulphuric acid.

BIRMINGHAM AND MIDLAND SECTION

At the meeting held at the University of Birmingham on February 21, Mr. F. R. O'Shaughnessy (vice-chairman) being in the chair, a paper entitled "A New Determination of the Specific Gravity of Solutions of Ammonia" was read by Messrs. N. W. Price and C. S. L. Hawkins (of Messrs. Chance and Hunt, Ltd., Oldbury).

The table published by Lunge in 1889 showing the relationship between the specific gravity and ammonia content of pure liquor ammonia had up to the present been accepted as the standard one. After a great number of determinations it was realised that the data given by Lunge were not strictly accurate. Invariably the analyses showed a lower percentage of ammonia than would be expected from the published tables. The authors concluded that the only satisfactory way of making new determinations was to weigh the ammonia solutions in a sealed vessel and then to estimate the whole of the ammonia contained in that vessel. A comparison of the tables brought out the following points: For specific gravities between 0·880 and 0·885 the new figures obtained were lower than Lunge's, the maximum difference being 0·33 per cent.; for specific gravities between 0·885 and 0·996 the new figures were higher than Lunge's, although the difference was very small.

Mr. F. R. O'Shaughnessy said the value of the great efforts made to eliminate error, experimental and personal, was alike commercial and scientific. Mr. W. A. Calder said the research followed a study of the behaviour of the curves produced from Lunge's figures. Dr. A. Parker said it would be interesting to work out, assuming the gravity of water to be 1 in the ammonia solutions, the volumes occupied by one gram of NH_3 in the solutions of different strengths.

Dr. A. C. Monkhouse (Fuel Research Department, Leeds University) next read a paper on "The Nitrogen of Coal and Ammonia Recovery."

The growing demands for nitrogen products, particularly for agriculture, were reviewed and the relative position of the by-product ammonia to the whole nitrogen industry was outlined. The respective merits of the Dumas and Kjeldahl methods of estimating nitrogen were discussed, the Dumas yielding a higher value of 0·1 to 0·2 per cent. for bituminous coals, due in the main to the Kjeldahl method taking no account of occluded nitrogen. An account of the present knowledge of the origin and nature of the nitrogen of coal was given and adventitious sources such as animal albuminoid matter and adsorbed nitrogen were mentioned. On distilling coal 11–18 per cent. of the nitrogen is obtained as ammonia, 50–80 per cent. is left in the coke, the remainder being found as free nitrogen, cyanogen and in the tar. The amount of nitrogen remaining in the coke was emphasised and the influence of carbonising coal in different atmospheres on the nitrogen of the coal was described in detail.

The nitrogen compounds in coal were converted on carbonisation into compounds which could be classed under three heads. (1) Those which yield ammonia direct on heating. (2) Those which yield ammonia on combination with hydrogen. (3) The so-called carbon "nitrides" which are split up by steam with the formation of ammonia. Hydrogen increased the yield of ammonia during carbonisation, but it was impossible to obtain ammonia by passing hydrogen over metallurgical coke, because the nitrogen was present in a form only decomposable by steam. During carbonisation the maximum evolution of hydrogen occurred at the time of maximum evolution of ammonia, thus increasing the yield of ammonia.

The passage of water gas through a retort did not increase the concentration of hydrogen, owing to the similarity in hydrogen content of the coal gas and water gas, but merely preserved the ammonia formed by diminishing the time of contact with the red hot coke. The work of Salmang, Pexton and Cobb has shown that with high temperature (1100° C.) coke and metallurgical coke the carbon-nitrogen remained constant during gasification by steam. In conclusion, the increased yields of ammonia of vertical retorts with steaming and the high yields of Mond producers were mentioned.

Mr. I. Graham thought there was a danger of error in dealing with low-temperature cokes, because the amount of gas adsorption was greater than with coal. Experiments with steam at high pressure, which appeared to have an oxidising action, were being carried out and these seemed to show an increased production of nitrogen. Dr. A. Parker said there was no doubt that steaming increased the nitrogen recovered as ammonia. Mr. E. C. Rossiter observed that in the course of seven years the production of synthetic nitrogen compounds had increased from 10 per cent. of the world's supply to a little over 21 per cent.

CHEMICAL SOCIETY

Presiding at an ordinary meeting on Thursday, February 21, Prof. W. P. Wynne announced, amid applause, that the Council had awarded the Longstaff medal to Prof. F. G. Donnan.

Mr. H. Hunter dealt with the first, and Prof. T. M. Lowry with the remainder, of the papers presented at the meeting :—

Investigations on the dependence of rotatory power on chemical constitution. Part XXII. Simple and complex rotatory dispersion. Harold Hunter.

A FORMAL and graphical analysis of the four possible cases of the Drude rotatory dispersion equation with one or two terms reveals the fact that, with the methods at present available, the classification of rotatory dispersion into "simple" and "complex" corresponding respectively to a one-term and a two-term Drude equation, is impracticable. It is shown that the method of plotting the reciprocal of the rotatory power against the square of the wave length does not distinguish between simple and complex rotatory dispersion, but that it serves to differentiate normal from potentially anomalous dispersion. A return to this older system of classification is therefore inevitable.

It thus follows that some current ideas on the chemical significance of rotatory dispersion must be considerably modified, and that there is no evidence that complexity of dispersion is ever symptomatic of chemical heterogeneity.

The rotatory dispersive power of organic compounds. Part XI. Sec-octyl alcohol and sec-octyl oxalate. T. M. Lowry and E. M. Richards.

(*a*) THE rotary dispersion of *sec.*-octyl a cohol can be expressed completely by one term of Drude's equation.

(*b*) The rotatory dispersion of *sec.*-octyl oxalate, like that of sodium tartrate, approximates closely to the inverse square law of Biot, but a two-term equation is required to express it accurately.

The rotatory dispersive power of organic compounds. Part XII. Borneol, camphor, and camphorquinone. Asymmetric atoms and asymmetric molecules. J. O. Cutter and T. M. Lowry.

(*a*) THE rotatory power of a strong solution of camphor in benzene has been measured for a series of 41 wave-lengths in the visible and ultra-violet regions. Shorter series of measurements have been made of a more dilute solution in benzene, and of solutions in cyclohexane and in acetone. Solutions in benzene of borneol and of camphorquinone (for a short series of wave-lengths only) have also been examined.

(*b*) The rotatory dispersion of camphor and its derivatives is complicated (i) by the presence of selective as well as of general absorption, (ii) by the presence of two dissimilar asymmetric carbon atoms in camphor and of 2, 3 or 4 in its derivatives, (iii) by the tendency of camphor to form molecular compounds with the solvent.

(*c*) The rotatory power of camphor in benzene (33·827 g. per 100 grams of solution) can, however, be represented very satisfactorily over a wide range of wave-lengths by the equation

$$[a] = -\frac{20{\cdot}138}{\lambda^2 - 0{\cdot}05428} + \frac{29{\cdot}384}{\lambda^2 - 0{\cdot}08720}$$

It is, therefore, thought likely that these two terms may actually express the two opposing factors which give rise to the "complex" rotatory dispersion of the compound. The negative term in this equation has a smaller dispersion-constant than the positive term; since the rotation-constant is also smaller, the resultant rotations are always positive. The dispersion is therefore *complex*, but not *anomalous*.

(*d*) The rotatory power of camphorquinone, over a narrow range of wave-lengths, is expressed by the equation

$$[a] = -\frac{13{\cdot}170}{\lambda^2 - 0{\cdot}22352}$$

This restricted equation is simple only because the rotation is here dominated completely by a strong absorption-band at 4830 A.U., the general absorption of the compound being too remote to influence its rotatory power in this region.

(*e*) In other cases only empirical equations have been deduced. In these, the various terms of the ideal complete equation are blended into one positive and one negative term, but it is doubtful whether these equations have any real physical meaning.

(*f*) Strong support is given to the view that, in studying the rotatory power and rotatory dispersion of complex compounds containing asymmetric atoms it is not sufficient to consider the dissymmetry of the molecule as a whole, since each asymmetric atom may contribute a separate share to the rotatory power of the compound, and a separate term or terms to the equations of rotatory dispersion.

The rotatory dispersive power of organic compounds. Part XIII. Halogen-derivatives of camphor. Optical superposition in the camphor series. J. O. Cutter and H. Burgess.

(*a*) MEASUREMENTS have been made of the rotatory dispersion of α- and α′-chlorocamphor, of αα′- and β-bromocamphor and of five isomeric dibromocamphors.

(*b*) In nine cases out of ten, the curves are *complex but normal*, *i.e.*, the rotation increases progressively as the wave-length diminishes, giving rise to quasi-hyperbolic dispersion curves, which do not exhibit any obvious anomalies; the dispersion is, however, not *simple* since it cannot be represented by a single term of Drude's equation.

(*c*) The dispersion can usually be represented by two terms of the Drude equation; but in one or two cases imaginary values are obtained for the constants, showing that the dispersions are of still greater complexity.

(*d*) In the one case of α′-bromocamphor, the negative term predominates over the positive term, and the complex dispersion becomes *anomalous*. The inflexion at 5455 A.U., maximum at 4710 A.U.,

3890 A.U., have all been [illegible] experimentally.

In opening the discussion, Dr. R. H. Pickard complimented Prof. Lowry on the painstaking manner in which he and his collaborators had performed the experimental work; despite the refinements employed, however, polarimetry must still be regarded as a comparatively crude operation. Mr. Hunter's contention that the difference between a one-term and a two-term equation could only be observed much below λ-3600 was significant. It appeared to the speaker that, although equations might be found to fit the results, it was not possible to use such equations for the classification of compounds.

Dr. T. Slater Price, remarking that the question at issue seemed to be one of accuracy of measurement, referred to the difficulty and uncertainty of visual comparisons of spectrum photographs, and recommended the use of an instrument, which had recently been described, whereby the diminution in intensity of a beam of light is balanced, using a selenium cell, against that produced by a neutral wedge in another beam from the same source.

Mr. J. O. Cutter said that the essential difference between simple and complex dispersions remains as evidenced by the cases of the octyl alcohol on the one hand, and camphor or camphorquinone on the other, although the difficulty of distinction was admitted. Variation of the characteristics of photographic plates was responsible for greater errors than the visual method of comparison of densities.

Mr. L. F. Hewitt cited the case of the aliphatic and aromatic secondary alcohols in support of the opinion that there is some connexion between the dispersive properties of a compound and its constitution; he agreed, however, that the distinction between simple and complex dispersion was frequently impossible in practice. It was of interest to note that in the case of the hydrogen phthalates of optically active secondary alcohols, the rotation of the ester appeared to be reversed in its alkaloidal salts.

Mr. Hunter suggested that the dispersion of *sec.*-octyl alcohol might become obviously complex if examined in the ultra-violet region beyond 3800Å., and nearer its characteristic absorption band. He asked how Prof. Lowry reconciled the position of the observed absorption band in the spectrum of camphor at 3500 Å., with that demanded by his equation at 3000 Å.

Prof. Lowry, replying, remarked that the graphical method was replaced, for exact work, by a more extended numerical test. The difficulty of detecting a complex dispersion made up of two positive components had already been emphasized, and experience had confirmed the practical difficulty of detection by visual readings only. Concerning the general question of the relation between optical and chemical complexity, complex dispersion may be ascribed (as in the case of tartaric acid) to the presence of two molecular species, or it may suggest a plausible explanation in suspicion of the chemical homogeneity of the medium—a suspicion which does not exist in the case of compounds showing simple dispersion. In any case, it was only the origin of the difference between the hyperbolic and more complex dispersion curves that was open to question. The absorption band of camphor at 3450 was measured in alcohol, whilst the rotatory dispersion was measured in benzene. The observation that a solution of camphor in benzene was more transparent than a solution in *cyclo*hexane suggested that benzene forms a loose molecular compound which is more transparent than camphor itself.

CORRESPONDENCE

LEAD SMELTING IN ENGLAND

SIR,—In your issue of February 8, Mr. H. L. Terry, in referring to a review by me of Dr. Smythe's "Lead: Its Occurrence in Nature, etc," calls attention to the small proportion of lead smelted in England as compared with the total quantity of that metal used here. Mr. Terry considers that my statement to the effect that the "lead produced by smelting does not exceed one-fifth of the total quantity of metal used for all purposes," over-estimates the quantity of English smelted lead.

It is probable that the war and post-war periods are more accurately represented by the figures quoted by Mr. Terry and this was known to me when reviewing Dr. Smythe's work, but in view of the fact that these figures are in every way abnormal, I considered it proper to utilise the figures for 1913 contained in Dr. Smythe's work, on pages 44 and 45, where it is shown that in that year, the United Kingdom produced 48,962 metric tons of lead, of which 30,000 was obtained from imported ores—the consumption of lead during that period being 191,400 metric tons. The figures contained in the monograph issued by the Mineral Resources Committee, written by T. C. F. Hall, 1921, do not seriously differ from those of Dr. Smythe.

I am grateful to Mr. Terry for his letter because it will help to focus attention on a question of great national importance, viz., the accelerated rate of decline of English lead mining since 1913, and it appears to be an open question whether English mining will recover or whether this industry, which is one of the oldest of English industries, will entirely disappear.

In discussing this point, the following extract from the monograph of Mr. Hall is of particular interest:—

"Since 1914 the abnormal conditions created by the war have had a serious effect upon the mining industry, and difficulties connected with shortage of labour and machinery have considerably curtailed outputs. On the other hand, the demand created for home ore supplies and the increase in the price of the metal have had the effect of directing attention to many derelict properties which, under normal conditions, were considered worthless, though the extensive nature of the operations necessary in most cases to bring these properties again to a

productive state has prevented any immediate results. Moreover, it is very doubtful whether, so far as lead is concerned, any considerable tonnages are available from many of these sources, for although in some instances increased mining costs combined with a fall in the value of the metal were the main factors in causing abandonment, it cannot be doubted that in others the root cause is to be found in the exhaustion or impoverishment of the deposits. With respect to financial burdens, reference may be made to the heavy pumping charges and to the difficulties of transport with which many mines had to contend. With regard to the former, attention is now being directed to the driving of deep adits in order to effect efficient and cheaper drainage, and such schemes are under construction or consideration in Shropshire, Flintshire and Leadhills. The latter difficulty may be met by means of aerial ropeways, as has been done in Shropshire."—I am, Sir, etc., C. A. Klein

Brimsdown, Middlesex
Feb. 20, 1924

THE FEDERAL COUNCIL

Sir,—I have read with interest your recent appeals for funds on behalf of the Federal Council. I am reminded of childhood days when I was requested by a larger and more knowing boy for pence to aid in sending missionaries to Central Africa. As a very ordinary chemist, the territory of Uganda and the reality of the Federal Council appear equally vague to me. You ask for funds, so you give the right to ask: What is the Federal Council? What does it do with its funds when it gets them? Who are its members, and how are they elected? It certainly may be a very able body, but its methods seem like those of certain Hush Committees that flourished in Whitehall during the late and, it would seem, forgotten, war. If one were presented with a full and definite statement as to the composition and activities of this mysterious body, one's purse strings *might* be loosened. At present it seems to be run by a small clique who carefully conceal from the general public what the Federal Council does.—I am, Sir, etc., J. V. M.

PATENTS

Sir,—I notice in your issue of January 25, 1924, a letter from a Limited Liability Company offering professional services in connexion with the obtaining of Patents and the registering of Trade Marks in Russia.

The facts referred to in this communication are, of course, well known in the profession, but it may be that your readers are not aware of the fact that Fellows of the Chartered Institute of Patent Agents, who are subject to [illegible] professional conduct of that Institute, ar[illegible]ed to solicit business.

Advertising "boost[illegible]e kind of the letter in question are discourag[illegible] prohibited in practically all the professions, and although the information itself may have been of interest to some of your readers, yet as the Society which publishes your *Journal* is composed very largely of professional men, I am surprised that you should have seen fit to publish it in such a form. Can it be that the Editorial vigilance was temporarily relaxed at the request of the Advertisement Manager? Perish the thought!

I enclose my card, but not for publication.—I am, Sir, etc.,

Chartered Patent Agent

[Note.—The Editorial vigilance is never relaxed; the letter referred to was published because we thought the information in it would be of interest to some of our readers.—Ed. *C. & I.*]

THE EPILATION OF SKINS

Sir,—Dr. H. C. Ross is to be congratulated upon the isolation and study of saproprotease, as described in his paper on "The Epilation of Skins," published in your issue of January 18, and I am sure that all chemists will rejoice that a medical man has made observations of such technical importance. It is all the more strange, therefore, that in some of his statements regarding matters which verge more toward the purely medical, that Dr. Ross has made some errors which I think must be pointed out lest they pass into current belief.

In the first place, Dr. Ross says: "The ancient Egyptians were the greatest of all embalmers. . . ." As scientific advisor to the National Selected Morticians I have had occasion to look up the Egyptian methods and compare them with those used by modern embalmers; and while everyone must marvel at the astounding skill and knowledge of these ancient people even over 5000 years ago, and realise that the submergence of their civilisation by Aryan inroads probably set the world's civilisation back many centuries, nevertheless no embalmer in any modern civilised community could possibly succeed with the methods they used.

Both Herodotus and Diodorus give accounts of the methods used by the Egyptian embalmers, and while these differ somewhat, it seems evident that there were several grades of embalming, that the process took much time (about 1–3 months), that it was very expensive, and that it would be forbidden by the local board of health in any community where one might attempt to practice it to-day. The body or face of the deceased was not shown to the family, but the mummy was swathed in bandages, drenched in perfumes, and hidden in a number of nested cases, on the outside of which were painted or carved pictures of the occupant. Besides, it was the extremely dry air of Egypt that was a great aid to results, as Egyptologists well know.

The better modern embalmer does his work quickly, at a small cost, and in a sanitary manner, and it is no discredit to the Egyptians that his work is vastly superior. The statement that the ancient Egyptians were the greatest of all embalmers is an error that should not be perpetuated, and that does not become true by repetition.

After properly pointing out the distinction between somatic and cellular death, Dr. Ross makes the following remarkable statement: "The first event that happens after an animal is slaughtered is that

the blood coagulates. Everybody knows that when blood is shed in a living animal it clots and so stops bleeding. But when an animal dies, the coagulation is general and universal throughout the whole system of blood vessels. This general coagulation occurs within three minutes. The hitherto fluid blood is changed into a firm, stringy mass or clot, from which a straw-coloured fluid exudes, called serum. Owing to the formation of the solid clot in the blood vessels, the former supple body of the animal becomes stiff—a rigid corpse, a condition known as rigor mortis."

The errors here must be patent to everyone who has had the least experience with these matters, and especially to butchers and to embalmers and to physicians. Thus in his "Clinical Hematology," Dr. John C. Da Costa says: "In normal blood the formation of the fibrin network becomes apparent within two or three minutes *after exposure to the air*, and the process is completed within seven or eight minutes" (the italics are mine). Perhaps Dr. Ross was thinking of shed blood. Then the time of coagulation is very variable, being rapid in some diseases (chlorosis, pneumonia, scarlet fever), and slow or inhibited in others (hemophilia, jaundice, pernicious anæmia, yellow fever). But this all refers to shed or extra-vascular blood. Within the body the coagulation is usually long delayed, the actual time depending on many factors, but generally running into hours.

Now as to rigor mortis, a consideration of the facts set forth in such an authority as "Chemical Pathology," by Dr. H. Gideon Wells, will show that the matter is not quite as simple as has been assumed by Dr. Ross. Rigor mortis is caused by a lasting contraction of the muscles, which become stiff and harder than in life, lose elasticity, and exhibit a turbid whitish appearance. Its onset and duration are both extremely variable, being hastened by heat and exercise prior to death, and retarded by cold. Clamping the abdominal aorta of a live rabbit will produce it, as will also certain poisons (quinine, monobromacetic acid), but renewing the circulation or perfusing with salt solution will remove it. Oxygen may delay or prevent it. Consideration of the work of Halliburton, von Fürth, Mangold, Krogh and others indicates that the coagulation of the blood itself has little to do with it, if anything. Probably one of the main factors is the formation of lactic or some other acid which influences the turgidity of the muscle colloids and is not swept out because the circulation has stopped.

The experimental facts mentioned on p. 58 remind one of the phenomenon called "skin-slip," and open up interesting possibilities as to the existence of autolytic as well as bacterial processes in the dead body.—Yours, etc.,

JEROME ALEXANDER

New York,
Feb. 8, 1924

SIR,—Referring to Dr. H. C. Ross's paper on the "Epilation of Skins" (*Chem. & Ind.*, 1924, p. 55), I should not have thought it worth while to criticise this paper had not the scientific correspondent of the *Leather World* taken the paper seriously.

I do not know why Dr. Ross should use the word "epilation" instead of the usual word "depilation," which is in common use. He speaks as though his medical knowledge places him in a class apart from the chemist, but it seems probable that chemists know more about the reactions which take place in the body than many medical men, who have little time to study chemistry.

Dr. Ross's theory is very wonderful, and his temerity is great, seeing that he had no knowledge of tanning except a superficial one gained by a few months' work in a modern tannery, and with this equipment he sets up his knowledge against that of men who have spent their lives at the work.

Dr. Ross says (p. 56) "in medicine little is known about un-hairing." I agree with this if his article represents the state of medical knowledge.

He also states that "Thrombin is a proteoclastic enzyme, acting in a similar manner to 'sapro-protease' (a fine sounding name for bacterial trypsin),' and that 'sapro-protease' becomes one hundred times more active in the presence of lime." Neither of these statements is true. I used to believe that old limes contained considerable quantities of enzymes derived from bacteria, but when these were looked for, they were not found to be present. As a matter of fact, old limes contain extremely small quantities of enzymes. I have examined hundreds of samples of old limes, and if Dr. Ross's statements were correct, it would have been quite easy to demonstrate the presence of these powerful enzymes. It is to be noted that Dr. Ross ignores the work of Stiasny on liming (*J.S.L.T.C.*, 1919, 129), the "Report on Liming Control," issued by the S.L.T.C., the paper by Wood and Law (*J.S.C.I.*, 1916, 585), in which it is shown that ammonia and sulphur compounds derived from the hair alone by chemical action are sufficient to unhair; see also the recent paper on the "Bacteria in Lime Liquors," by L. Collett, (*J.S.L.T.C.*, 1923, 418.)—Yours, etc.,

JOSEPH T. WOOD

Turney Brothers, Ltd.,
Trent Bridge Leather Works, Nottingham
February 22, 1924

Dr. Jacques Loeb, head of the Division of Physiology in the Rockefeller Institute for Medical Research, who died in Bermuda recently, had an international reputation as a physiologist. His work covered a wide range being related largely to the inter-relation of nervous action with chemical reactions. He did much to show that chemical conceptions can be applied to explain the peculiar "physical" properties of colloid materials, and that the behaviour of these is comparable with that of crystalloids when determined under proper conditions.

PERSONAL AND OTHER ITEMS

BAYER 205 AND FOURNEAU 309

(From a Correspondent)

Some years since the Bayer Company produced a synthetic material which appeared to be remarkably efficient as a cure for sleeping sickness; this was called Bayer 205; the composition and constitution of this new remedy were kept secret because it appeared that the substance is the key to tropical Africa and that the German Government must "be required to safeguard this discovery for Germany; its value is such that any privilege of a share in it granted to other nations must be made conditional upon the restoration to Germany of her colonial Empire."

It was indicated at the time (this Journ., 1922, 41, 368 R) that it was only possible to hide the identity of Bayer 205 because of the non-existence in this country of an efficient co-operation between the organic chemists and the Medical Research Councils.

In the Annual Report of this Society for 1921 (Vol. VI., p. 537) Dr. H. King stated that Bayer 205 appeared to belong to the group of ureas formed by the action of carbonyl chloride on the corresponding amino-derivative of the substance produced by the introduction, twice, of *p*-nitrobenzoyl chloride into H-acid. This is now confirmed by Fourneau and his co-workers who announce in the *Comptes Rendus* dated February 11, 1924, that Fourneau 309 seems to be identical with Bayer 205. The compound prepared by Fourneau is a symmetrical urea of meta-amino-benzoyl-meta-amino-paramethyl-benzoyl-1-naphthylamine-4.6.8-trisulphonate of sodium; the constitution of which certainly resembles the formula suggested by Dr. King. M. Fourneau and his associates are to be congratulated on their success and thanks are also due to Dr. King, who, your readers will remember, is in charge of the Department of Biochemistry and Pharmacology in the National Institute for Medical Research at Hampstead.

* * *

Mr. F. S. Sinnatt, M.B.E., M.Sc.Tech., has resigned his lectureship in fuels in Manchester University to take up the post of Assistant Director of the Fuel Research Board.

Mr. A. Chaston Chapman, F.R.S., who is retiring from the presidency of the Institute of Chemistry, is to be succeeded by Prof. G. G. Henderson, Regius Professor of Chemistry in the University of Glasgow.

Dr. C. K. Ingold, lecturer in organic chemistry in the Imperial College of Science and Technology, has been appointed professor of organic chemistry in the University of Leeds, as from October 1 next, on the retirement of Prof. J. B. Cohen, F.R.S. Dr. Ingold, who carried out valuable work for the Chemical Warfare Committee during the war, is the author of numerous papers dealing with tautomerism and other problems of the structure of organic compounds.

BRITISH INDIA

Sugarcane Crop of 1923-24

The final memorandum of the sugarcane crop, based on reports received from provinces, which contain, on an average, 99 per cent. of the total area under sugarcane in British India, estimates that the area sown is 2,882,000 acres, as against 2,740,000 acres last year. This area does not include Mysore, from which information is not forthcoming. The total yield (again excluding Mysore) is estimated at 3,240,000 tons, as against 3,044,000 t. last year. These estimates show an increase of 7 per cent. in area, and of 8 per cent. in yield compared with 1922-23. The condition of the crop is reported to be generally good.—(*Ind. Tr. J., Feb.* 7, 1924.)

FRANCE

Metallurgy in 1923

The position of French metallurgy at the beginning of 1924 shows much improvement. The average monthly production of cast iron and steel in 1913 was 43,400 and 390,000 tons respectively, whereas the respective figures for 1923, including the production of Lorraine, are below these averages by only 80,000 t. for cast iron and 40,000 t. for steel. The number of blast furnaces alight has decreased from 166 in January, 1923, to 125 in January, 1924, the total number of blast furnaces being 219. The production of cast iron was 520,700 t. in 1913, 5,128,608 t. in 1922 and 5,299,586 t. in 1923. Steel production which was 4,687,000 t. in 1913 became 4,471,278 t. in 1922 and 4,976,869 t. in 1923. In Lorraine, the production in 1923 was 1,867,164 t. of cast iron and 1,576,059 t. of steel. Considering the production of 564,655 t. of cast iron and 525,509 t. of steel in December 1923, the annual production could amount to 6,800,000 t. of cast iron and 6,300,000 t. of steel, an attainable output as it corresponds only to the utilisation of 119 blast furnaces, 51 being in working order but held in reserve, and 43 under construction or repair. Exports totalled 592,086 t. of cast iron and 1,847,238 t. of iron and steel compared with imports of 63,541 t. of cast iron and 663,876 t. of iron and steel.

Production of Potash and Salt in December, 1923

During 1923, the French production of potash totalled 1,338,333 tons, equivalent to 27,741 t. of K_2O. The output of salt increased slightly from 1768 t. to 102,899 t.

GENERAL

Nitrate Position

According to the *Manchester Guardian* the nitrate position is improving, for at the sale last week by the Association of Nitrate Producers, applications were received for 329,000 tons, at 19s. 3d. per 100 kg. for 95 per cent. and 20s. per 100 kg. for the 96·1 per cent. nitrate. Only 200,000 t. was released, however, but a further 50,000 t. has been offered for delivery also in June.

REVIEWS

Einfache und Fraktionierte Destillation in Theorie und Praxis. By Prof. C. von Rechenberg. Pp. xv+814. *Leipzig: Schimmel & Co.*, 1923. *Price: paper*, 17 *gold marks; bound*, 18 *gold marks*.

Readers of Prof. v. Rechenberg's treatise, *Theorie der Gewinnung und Trennung der aetherischen Oele durch Destillation*, will welcome the appearance of this book, which is described in the preface as a second edition of a part of the earlier volume.

The first hundred pages of the book are devoted to a consideration, mostly theoretical, of such subjects as vaporisation and solution, methods of proving the purity of a single substance, vapour pressures and boiling points, dissociation, specific heat, heat of vaporisation, vapour density, volatilisation of solids and measurement of temperature. The most important methods of determining the vapour pressures and boiling points of pure substances are then very fully and clearly described, and about 160 pages are occupied by tables of the vapour pressures at different temperatures and the boiling points under different pressures of nearly five hundred substances, bibliographical references for each substance being given in the following 37 pages.

Relations between the temperature and pressure of saturated vapours are next discussed, and the methods of calculating boiling points by the rules of Ramsay and Young and of Dühring are explained. It is pointed out that the vapour pressure curves of many pairs of liquids intersect, and the points of intersection—temperature and pressure—are given for a large number of liquids.

The properties of mixtures, including pairs of non-miscible liquids, are dealt with in the second part of the book. As might be expected, the subject of steam distillation is very fully and ably treated, and there is an interesting discussion of the vexed question as to the relative efficiency of steam distillation and plain distillation under reduced pressure.

A few pages are devoted to a consideration of the solubility of liquids in liquids and of critical solution temperatures, and then follows a detailed description of the measurement of the vapour pressures and boiling points of mixtures and of the composition of the liquid and vapour phases of a solution. The older researches on these subjects are well and fully described, but it is unfortunate that the important investigations of Rosanoff and his co-workers have been overlooked.

After describing the work of Konowalow, on mixtures of the lower alcohols and fatty acids with water, the formation of azeotropic mixtures is explained and their bearing on the distillation of mixtures is discussed. Tables of binary and ternary mixtures of minimum boiling point and of binary mixtures of maximum boiling point are given, and there is a clear account of the methods of determining the composition of such mixtures and of separating the components of an azeotropic mixture by distillation with a third substance.

The third part of the book is devoted to simple and fractional distillation on the large scale and in the laboratory. There is, first, an excellent account of the steam distillation of ethereal oils, followed by a description of the distillation of the tars from brown coal and ordinary coal and of petroleum. Under the last named head, the cracking of oils is briefly discussed. The various forms of apparatus employed for fractional distillation on the large scale are described in detail, and a considerable number of still-heads devised for use in the laboratory are figured and described.

There is finally a table of boiling points of elements and compounds arranged in alphabetical order and occupying some 48 pages.

The index, so far as names of authors are concerned, is not so complete as it might be; for example, there is a nearly full-page illustration of Zawidski's well-known apparatus for determining the composition of the liquid and vapour phases of a mixture, but Zawidski's name does not appear in the index.

The book is well printed, the illustrations are clear and good, and the author is to be congratulated on the production of an excellent and useful treatise.

SYDNEY YOUNG

Systematic Survey of Rubber Chemistry. By C. W. Bedford *and* H. A. Winkelmann. *Pp.* 325. *New York: The Chemical Catalog Co., Inc.*, 1923. *Price* $7.0.

The long sub-title to this volume is liable to create some misconception as to its scope, for, as the authors state in an explanation of its objects, the following subjects, namely, Analysis of Rubber, Synthetic Rubber, Physical Properties of Rubber, Rubber Testing, Rubber Botany, Diseases of Rubber Trees, Reclaimed Rubber, have been omitted, and articles dealing with them have been included only where they contain data relative to molecular structure, ageing, accelerators or similar subjects. In the same way we find that the introductory chapters "summarising the present status of rubber chemistry" consist of two articles, the one by Dr. L. B. Sebrell on "Organic Accelerators of Vulcanisation," the other on "Theories of Vulcanisation" by Dr. W. J. Kelly. Both of these articles, it may be said, are critical and excellent as regards manner and matter, and the conclusion reached by Dr. Kelly that vulcanisation is a purely chemical process, and his reasons for this view, will be read with more than general interest. The "survey" is arranged in three main divisions: Author Index, Subject Index, and Patent Index. The first constitutes a bibliography with the authors listed alphabetically. The works are set out in approximately chronological order, with a reference number for each article or group of patents. This reference number is used for cross-indexing between the various divisions of the survey. For example *Smith G.* (23) would refer to the tenth item under G. Smith in the Author Index. The Subject Index, arranged alphabetically, correlates the data relative to the various subjects treated, and the abstracts of the subject matter are to be considered as indicative of the nature of the work and not as

condensations of data. In other words, it is not sought to make a reference to the original publication unnecessary. A valuable feature of the references is that these are not confined to the original (frequently more or less inaccessible) but embrace abstracts, discussions and the like contained in technical or trade journals and in books. The first edition of a work of a more or less encyclopædic nature must necessarily contain a number of imperfections and omissions, and the authors, conscious of this, ask readers to make note of such errors for the benefit of future editions. It is evident that the preparation of Messrs. Bedford and Winkelmann's volume has involved an immense amount of patient and critical labour, and it should prove a boon to all of those who are in any way seriously interested in the chemistry or technology of rubber.

PHILIP SCHIDROWITZ

PARLIAMENTARY NEWS

HOUSE OF COMMONS

The Proposed British and German Dyestuffs Agreement

Replying to Mr. Turner, Mr. Webb stated that proposals for an arrangement have been for some time under discussion between the British Dyestuffs Corporation and the Interessen-Gemeinschaft. As the Board of Trade was not a party to these negotiations, and as the discussions had not terminated, no conclusions had been laid before the Board, but should a draft agreement be submitted, it would require the serious consideration of the Government, and the question of making a statement to the House would be considered without delay.—(Feb. 15.) Mr. Webb said, in reply to Mr. Waddington, that he was aware that the appointments of a limited number of research chemists had been terminated within the past three months, owing to a re-organisation of the research work of the Corporation. With regard to Mr. Waddington's statement that the Corporation has hitherto refused to appoint to the directorate persons with technical and scientific knowledge of dyestuffs manufacture, he understood that an invitation to join the Board of the Corporation was now under consideration by a distinguished scientist.—(Feb. 19.)

Ammonium Sulphate (Supplies)

Answering Mr. F. Martin, Mr. Buxton said that he was aware that in some districts the supply of ammonium sulphate for immediate delivery in the spring of last year was not large. He was advised that the supplies available this year would be sufficient, but said that the matter would be kept under consideration.—(Feb. 18.)

Trade Facilities (Money)

At the Committee of the whole House, under Standing Order No. 71A, the motion was proposed: That it is expedient to amend the Trade Facilities Acts, 1921 and 1922, (1) by increasing from fifty million pounds to sixty-five million pounds the limit on the aggregate capital amount of the loans the principal or interest of which may be guaranteed thereunder; and (2) by extending to March 31, 1925, the period within which guarantees may be given under the Trade Facilities Act, 1921.

White Lead in Paint

In reply to Mr. G. White, Mr. Shaw said that the question of sanctioning the Convention on the use of white lead in paint was under consideration by the Government, and the decision would be announced as soon as practicable.—(Feb. 14.)

Anglo-Persian Oil Co.

Replying to various questions, Mr. Snowden said that the Government had no intention of re-considering the decision not to sell the shares in the Anglo-Persian Oil Co., as it would not have been in the national interest to part with them to a combine, especially as Naval interests, for which the original investment in an independent oil company was made, would have been seriously prejudiced.—(Feb. 14.)

Microscope Stains

Mr. Graham, in reply to Mr. Keens, said that bottles containing stains for use in microscopic work, which "necessarily have to be imported from Germany," may be delivered to the various research departments of hospitals and other laboratories without being opened by the Department of Customs and Excise, provided it was indicated in the Customs entry that the alcoholic strength was not to be tested, and the appropriate duty was paid.—(Feb. 14.)

Dyestuffs

Answering Mr. Waddington, Mr. Alexander said that the quantity of coal-tar dyestuffs of United Kingdom manufacture exported during 1913 was 60,733 cwt., valued at £206,109, an average of £3 7s. 10d. per cwt. The exports in 1923 amounted to 126,187 cwt., valued at £1,031,903, or an average of £8 3s. 7d. per cwt.—(Feb. 14.)

German Reparation (Recovery) Act

Mr. Graham, answering Mr. Harmsworth, said that the negotiations with representatives of the German Government on the subject of the Reparation Recovery Act had resulted in an agreement to reduce the rate of the levy from 26 per cent. to 5 per cent., in respect of goods imported on or after February 26. In order to guarantee that no part of the levy shall be charged to British importers, the German Government had agreed to arrange for the compensation of the German exporters at a later date, and to make it a punishable offence to charge any part of the levy to the British importer. Customs receipts in respect of all goods imported prior to February 26 (*i.e.*, those at the rate of 26 per cent.) would be reimbursed by the German Government in Gold Bonds. Further details in regard to these Gold Bonds would be published in the next issue of the *Board of Trade Journal*.—(Feb. 25.)

COMPANY NEWS

BRITISH ALIZARINE CO., LTD.

The net profit for 1923 is £44,072, and, with £36,550 brought forward, it is proposed to write off £20,000, carry forward £42,914 and pay a dividend of 5 per cent.

JOSEPH CROSFIELD & SONS, LTD.

The balance at credit of profit and loss, amounting to £331,269 for the year ended November 30, 1923, has been appropriated as follows :—£20,000 to dividend on the 5 per cent. cumulative pre-preference shares ; £30,000 on the 6 per cent. cum. pref. shares ; £65,000 on the 6½ per cent. cum. pref. shares ; £112,500 on the 7½ per cent. "A" cum. pref. shares ; and £100,000 on the ordinary shares at the rate of 10 per cent. The carry-forward totals £3769.

BRADFORD DYERS' ASSOCIATION, LTD.

After making sundry deductions, trading profits for 1923 are £1,032,152, and the net profits £739,227, £448,369 being brought forward. It is proposed to bring the reserve to £1,125,000 by adding £125,000, to pay a final dividend on the ordinary shares of 4s. per share, making 5s. (25 per cent.) per share for the year and to carry forward £473,477.

LANTARO NITRATE CO., LTD.

An interim dividend is declared of 5 per cent. (5s. per share) for 1924. No dividend has been paid since 1919, when 16 per cent. (tax free) was distributed, but the capital was increased in 1923 to £4,000,000 and a bonus was given of 3 new shares for every 7 held.

BORAX CONSOLIDATED, LTD.

At the annual meeting on February 19, the chairman, Lord Chichester, said that the financial position of the company was strong. Second mortgage debenture stock amounting to £297,784 had been issued to provide money for increasing the manufacturing capacity of the company. A compromise had been made with the Angora Government, so that shipments from the Turkish mines would be resumed. The accounts were passed. The net profit to September 30, 1923, was £442,753 (£417,900 in 1921-22), on an issued share capital of £2,550,000, debentures amounting to £1,916,450, and reserves to £1,053,131. To commemorate the completion of 25 years of activity, holders of deferred ordinary shares will receive a bonus of 2½ per cent. in addition to a dividend of 12½ per cent.

UNITED ALKALI CO., LTD.

A dividend is announced of 6 per cent. less tax on the ordinary shares, making 10 per cent. for 1923, leaving £96,000 to be carried forward. The last report covered 1921 and 1922, and the total dividend for that period was 10 per cent. and the carry forward £386,735. Out of this sum, a capital bonus equal to 50 per cent., and requiring £300,000 was distributed to ordinary shareholders.

WILLIAM GOSSAGE & SONS, LTD.

The accounts for the year ended November 30 last show, after providing for all charges, a credit balance of £174,826, of which £22,500 is allocated for dividends on the 5 per cent. first cumulative preference shares, £48,750 for the 6½ per cent. cumulative preference shares, and £100,000 for the ordinary shares at 20 per cent., leaving £3,576 to be carried forward.

REPORT

REPORT ON THE ECONOMIC AND FINANCIAL CONDITIONS IN ECUADOR, DATED SEPTEMBER, 1923. *By* R. C. MICHELL, *Chargé d'Affaires, Quito. Department of Overseas Trade. Pp.* 23. *H.M. Stationery Office*, 1923. *Price* 9*d.*

Since the publication of the last report on Ecuador (*cf. Chem. and Ind.*, 1923, 352) the economic situation of the country has gone from bad to worse. Excessive imports have led to a serious state of affairs and the Government has appealed to the country to develop further its natural resources. It is hoped to find foreign capital to aid this development. These large importations were made without respect of the ability of the buyers to pay and it became very difficult to obtain the necessary drafts owing to Government control of the exchange. The market is most unhealthy and British exporters receiving orders from Ecuador are advised to stipulate cash remittances to accompany orders. Imports in 1921 were valued at S/23,486,183 (£1=10 sucres at par, but about 25 now). Of this total the United States supplied 38 per cent. and Great Britain 30 per cent. The principal items were textiles, 26% ; foodstuffs, 11% ; hardware, 10% ; machinery, etc., 9% ; clothing, 5% ; minerals, etc., 5% ; drugs, 4%.

Exports in 1921 amounted to S/33,968,899, the principal items being cocoa, representing 60% ; ivory nuts, 13% ; and coffee, 9%.

The manufacturing industries of the country are small. There is a cement factory which, if it proves successful, will save the country some half-million sucres at present annually for imported cement. The main article produced in the country is cocoa, and the poor crops gathered in the last few years have been the cause of the exchange trouble. The decrease in output seems likely to continue.

The country is not rich in available mineral resources. In 1922 about 4000 oz. fine of gold and 70,000 oz. fine of silver, valued at S/40,400 and S/100,000 respectively were exported. Oil is found in parts of the country ; for the six months ending June 30, 1923, the average monthly output of oil was 4720 gallons of kerosene and 6872 gal. of gasolene. Lignite is found in some parts and three veins of anthracite are reported in the province of Chimborazo. There is evidence of the existence of other mineral deposits, such as manganese, mercury, platinum, etc., but transport difficulties prevent their development.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The demand for heavy chemicals is well sustained, but there are no fundamental changes in prices to report.

Acetic Acid, 40% tech. ..	£24 per ton. Fair inquiry.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5½d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76% ..	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton carr. paid. In
Sod. Bisulphite Powder 60/62%	£19—£20 10s. per ton according to quantity. f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis ..	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included

RUBBER CHEMICALS

Antimony sulphide ..	Expected to advance in sympathy with the crude metal.
Golden	5½d.—1s. 3d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Cadmium Sulphide ..	4s. per lb.
Carbon Bisulphide ..	£24—£26 10s. per ton according to quantity.
Carbon Black	Prices continue low but expect to advance in the Spring. T or three case lots can now bought at 5½d. per lb. ex wha For direct shipment in qua tity the price is about per lb. c.i.f.
Carbon Tetrachloride ..	£56 per ton, drums free.
Chromium Oxide ..	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Dearer owing increased cost of rape seed Good demand.
Lamp Black	40s. per cwt., barrels free.
Lead Hyposulphite ..	7½d. per lb.
Lithopone	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according quality.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep ..	3s. 4d.—3s. 6d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according quality.

WOOD DISTILLATION PRODUCTS

All acetates command a good trade and there appears more healthy prospect in the charcoal market.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Deman active.
Grey	£22 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according t grade and locality. Market quiet
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. 6d. per gall. 60% O.P. Du market.
Solvent	5s. 6d. per gall. 40% O.P. Du market.
Wood Tar	£5—£6 per ton according to grad Demand not very brisk. Ampl supplies.
Brown Sugar of Lead ..	£42 per ton. Demand more active

TAR PRODUCTS

Acid Carbolic—	
Crystals	8½d. per lb. Some business pass ing at lower prices.
Crude 60's	1s. 10d.—2s. per gall. Firmer, with more inquiry.
Crude 60's	1s. 10d.—2s. per gall. Little busi ness passing, but more inquiry.
Acid Cresylic, 97/99 ..	2s.—2s. 3d. per gall. Steady business.
Pale 95%	1s. 10d.—2s. 2d. per gall. Good demand.
Dark	1s. 11d. per gall. Steady business.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9d.—10d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons

Standard Motor .. .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 4½d.—1s. 7d. per gall.
Pure .. .. 1s. 8d.—1s. 11d. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 11½d. per gall. Few inquiries.
Middle Oil .. .. } 8½d.—9½d. per gall. according to grade and district. Market very firm. Demand good.
Heavy .. .. }
Standard Specification }
Naphtha—
Crude .. .. .. 9d. per gall. } More inquiry. Prices show upward tendency.
Solvent 90/160 .. 1s. 1d.—1s. 3d. }
Solvent 90/190 .. 1s. 1d.—1s. 3d. }
Naphthalene Crude—
Drained Creosote Salts £6—£8. Fair business.
Whizzed or hot pressed £8—£14 per ton. Price nominal. No business.
Naphthalene—
Crystals .. .. £16 10s. per ton.
Flaked .. .. £17 per ton.
Pitch, medium soft .. 52s. 6d.—62s. 6d. per ton, f.o.b. Market weak. Few sellers.
Pyridine—90/140 .. 14s.—14s. 6d. per gallon. Fewer inquiries.
Heavy .. 11s.—12s. Steady with fair business.

INTERMEDIATES AND DYES

Business in dyestuffs has improved appreciably with orders being given for larger quantities. Prices of intermediates made directly from pure benzol have been raised, owing to the increased cost of the latter.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 6d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 11d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 6d. per lb. Better demand.
Acid Sulphanilic .. 10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7½d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7½d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 29/31° C. .. 5½d.—6d. per lb. Demand quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Market quiet.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Market quiet.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethyaniline .. .. 2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. 3d. per lb. d/d.
Monochlorbenzol .. .. £63 per ton.
α-Naphthol .. .. 2s. 6d. per lb. d/d.
β-Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 5d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 5d. per lb. d/d.
Nitrobenzene .. .. 5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. .. 11½d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol.. 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 4s. 6d. per lb. d/d.
p-Phenylene Diamine .. 10s. 6d. per lb. 100% basis d/d.
R. Salt .. .. .. 3s. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 7d. per lb. 100% basis d/d.
o-Toluidine .. .. 7d.—8d. per lb.
p-Toluidine .. .. 3s. 10d.—4s. 5d. per lb. d/d.
m-Toluylene Diamine .. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. .. £52 per ton.
Acid, Acetyl Salicylic .. 3s. 6d.—3s. 9d. per lb. Steady demand.
Acid, Benzoic .. .. Commercial acid dearer at 2s. 9d. per lb. B.P. quality remains scarce at 4s. per lb.
Acid, Boric B.P. .. Cryst. £54 per ton. Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric .. .. 18s.—20s. per lb.
Acid, Citric .. .. 1s. 5½d. per lb., less 5% for ton lots. Market firm.
Acid, Gallic .. .. 3s. per lb. for pure crystal. Steady market.
Acid, Pyrogallic, Cryst. .. 6s. per lb., for 28 lb. lots.
Acid, Salicylic .. .. Cheaper at 2s. 1d. per lb. for quantity.
Acid, Tannic .. .. 3s. 3d. per lb. for B.P. quality.
Acid, Tartaric .. .. 1s. 1d.—1s. 1½d. per lb. less 5%. Firmer with more demand. Continental acid offered at 1s. per lb. less 5% c.i.f. U.K. port.
Amidol .. .. .. 9s. per lb. d/d.
Acetanilide .. .. 3s. per lb. Weak.
Amidopyrin .. .. 13s. 6d. per lb. Demand negligible
Ammon. Benzoate .. 4s. per lb. English make.
Ammon. Carbonate B.P. £35 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make. Market neglected.
Barbitone .. .. .. 16s. 6d. per lb.
Benzonaphthol .. .. 6s. per lb. Firmer.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides— Per lb.
Potassium .. .. 9d.—10d. } Steady market.
Sodium .. .. 9½d.—10d. }
Ammonium .. .. 11d.—1s. }
Calcium Lactate .. 2s. 9d. per lb. for best English make. Market firm.
Chloral Hydrate .. .. 3s. 9d. per lb.
Chloroform .. .. 2s. per lb. for cwt. lots.
Creosote Carbonate .. 6s. 6d. per lb. Little demand.
Guaiacol Carbonate .. 13s. per lb. for small stocks available. More inquiry. available. Slightly weaker.
Hexamine .. .. 3s. 9d.—4s. per lb. for foreign makes. Firmer.
Homatropine Hydrobromide .. .. 30s. per oz.

Iron. Ammon. Citrate, B.P.	1s. 11d.—2s. 3d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B. P.	55s. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Prices reduced. Market quiet.
Red oxide	4s. 9d.—4s. 10d. per lb.
Corrosive sublimate	3s.—3s. 1d. "
White precip.	4s. 1d.—4s. 2d. "
Calomel	3s. 5d.—3s. 6d. "
Methyl Acetanilide	20s. per lb.
Methyl Salicylate	2s. 9d.—2s. 11d. per lb. for carboys. Slightly easier.
Methyl Sulphonal	24s. per lb. Scarce.
Methylene di-tannin	7s. 6d. per lb. In good demand.
Paraformaldehyde	3s. 6d. per lb., without much inquiry.
Paraldehyde	1s. 6d.—1s. 8d. per lb.
Phenacetin	7s. per lb. Dull.
Phenazone	7s. 9d. per lb. for cwt. lots. Considerable competition.
Penolphthalein	7s. 6d. per lb.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s.—90s. per cwt., less 2½%. Firm market. Inquiry good.
Potass. Citrate	1s. 8d.—2s. per lb.
Potass. Ferricyanide	3s. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. lb., 1-cwt. kegs included.
Potass. Permanganate	8½d.—9d. per lb. for B.P. crystal English make.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	6s. 3d. per lb.
Salol	4s. per lb. Rather dull.
Silver proteinate	10s. per lb.
Sod. Benzoate, B.P.	3s. 3d. per lb. In more plentiful supply.
Sod. Citrate, B.P.C., 1923	1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.
Sod. Hyposulphite—	
Photographic	£14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	76s. 6d.—81s. 6d. per cwt., according to quantity. Prices reduced.
Sod. Salicylate	Powder 2s. 9d.—2s. 11d. per lb., Crystal at 2s. 10d.—3s. per lb. Market weaker.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	18s. 6d. per lb.
Tartar Emetic	1s. 4d. per lb.
Thymol	13s. 6d.—14s. 6d. per lb. for good white crystal from ajowan seed. Distinctly firmer.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	13s. 6d. "	
Amyl Acetate	3s. "	
Amyl Butyrate	7s. 3d. "	
Amyl Salicylate	3s. 6d. "	
Anethol (M.P. 21/22° C.)	3s. 9d. "	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. 3d. "	
Benzyl Alcohol free from Chlorine	3s. 6d. "	
Benzaldehyde free from Chlorine	3s. 3d. "	
Benzyl Benzoate	3s. 9d. "	
Cinnamic Aldehyde Natural	18s. 6d. "	
Coumarin	21s. "	
Citronellol	19s. "	
Citral	10s. "	
Ethyl Cinnamate	10s. "	
Ethyl Phthalate	3s. 9d. "	
Eugenol	10s. "	Cheaper.
Geraniol (Palmarosa)	35s. "	Cheaper.
Geraniol	10s.—17s. 6d. per lb.	
Heliotropine	8s. 6d. per lb.	
Iso Eugenol	15s. 9d. "	
Linalol ex Bois de Rose	20s. "	
Linalyl Acetate	20s. "	
Methyl Anthranilate	9s. "	Advanced.
Methyl Benzoate	6s. "	
Musk Ambrette	52s. 6d. "	
Musk Xylol	19s. "	
Nerolin	4s. "	
Phenyl Ethyl Acetate	10s. "	
Phenyl Ethyl Alcohol	16s. "	
Rhodinol	62s. 6d. "	Cheaper.
Safrol	1s. 10d. "	
Terpineol	2s. 9d. "	Advanced.
Vanillin	26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	14s. 6d. per lb.	
Anise Oil	1s 11d. "	
Bergamot Oil	14s. 6d. "	
Bourbon Geranium Oil	29s. 6d. "	
Camphor Oil	75s. per cwt.	
Cananga Oil, Java	9s. 4½d. per lb.	
Cinnamon Oil, Leaf	5¼d. per oz.	
Cassia Oil, 80/85%	9s. 6d. per lb.	
Citronella Oil—		
Java 85/90%	4s. 10d. "	
Ceylon	3s. 7½d. "	
Clove Oil	8s. 7½d. "	Cheaper.
Eucalyptus Oil 70/75%	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	24s. 6d. per lb.	
Lemon Oil	3s. 1d. "	
Lemongrass Oil	2½d. per oz.	
Orange Oil, Sweet	12s. 6d. per lb.	
Otto of Rose Oil—		
Bulgarian	34s. per oz.	
Anatolian	26s. per oz.	
Palma Rosa Oil	18s. 6d. per lb.	Cheaper.
Peppermint Oil—		
English	70s. per lb.	
Wayne County	17s. 9d. per lb.	Advanced.
Japanese	14s. 6d. per lb.	Advanced.
Petitgrain Oil	9s. 6d. per lb.	

TRADE NOTES

Official Trade Intelligence.

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number.

Canada: Drugs, (205); *Norway*: Earthenware, (211); *Peru*: Drugs, (220); *Porto Rico*: Cement, (22033/F.W./M.C.12); *Sweden*: Chemicals, dyestuffs, (216); *United Kingdom*: Illuminating oils (The Secretary, Trinity House, Tower Hill, London, E.C. 3); *United States*: Steel, (217); Creosote, (22087/F.W./C.C./2); Brass, (21955/F.W./E.C./2).

Trade Information

A Vacuum Pump of extremely interesting design has been put on the market by the Central Scientific Co., of 460, E. Ohio Street, Chicago, under the name of the "Cenco Hyvac Pump." As the result of trials carried out by Prof. C. T. Krupp and C. S. Palmer, of the Laboratory of Physics, University of Illinois, it was concluded that the Cenco Hyvac Pump was quite rapid, reaching a surprisingly high vacuum and that it was therefore well suited to be used as a force pump to any large throated rapid-acting mercury vapour pump. This conclusion was reached after the pump had been in almost continuous uso over a long period. According to the makers the pump produces a vacuum of 0·001 mm. without the use of a preliminary or backing pump, and they claim that it constitutes the smallest, most efficient and most economical outfit for obtaining a vacuum of 0·001 mm. that has ever been produced. Measuring 4½ by 4½ by 7⅜ in., on a base 9 by 18 in., the pump runs at 240 revolutions per minute, requires only 1/12 h.p. to operate it and weighs only 16¼ lb. It is supplied mounted or unmounted, with or without an electric motor, the price unmounted being $50, which includes the provision of a pulley and a supply of oil especially selected for high vacuum work. It is of interest to call attention to this pump in view of the modern demand for efficient vacuum pumps that will produce a high vacuum and maintain it during long periods of continued use.

Messrs. Manlove, Alliott and Co., Ltd., have sent us copies of two circulars, ono of which illustrates some of the many varieties of plant supplied by this firm for the chemical industry, *e.g.*, filter presses, stearine presses, evaporating plant, oil-refining plant, drying machines and centrifugal machines. The other circular illustrates hydro-extractors and washing and ironing machines designed more particularly for the laundry trade. Messrs. Manlove, Alliott states that these circulars refer to but few of many different types of apparatus and the firm's services are at the disposal of clients whether for advice or experimental work. Copies of the circulars and further information can be obtained from Messrs. Manlove, Alliott and Co., Ltd., at Bloomsgrove Works, Nottingham.

The Technical Advertising Service, whose work was recently reviewed in these columns, is now completely installed in its new offices at 52, Bedford Square, London, W.C. 1 (Telephone: Museum 64; Wire: Systemized, West Cent. London).

Imports of Medicines from Great Britain

The *Journal Officiel* has published a notice relating to the importation into France of certain medicines from Great Britain. According to the Law of April, 1923, medicines of foreign origin and coming under the heading 316 of the Customs Tariff (not including serums, vaccines, etc.) may be imported into France, even if not registered in official pharmacopœias, provided the labelling satisfies the conditions prescribed by law and when such importation takes place from countries which offer similar advantages to France. After consideration of the regulations concerning the importation of medicines into Great Britain, it has been decided to allow the importation of medicines from Great Britain.

French Fertiliser Trade in 1923

The French imports of fertilisers in 1923 were:—Mineral superphosphates, 66,773 metric tons, bone superphosphates 6593 t., basic slag, 41,682 t., nitrate of soda, 268,435 t. (262,358 t. from Chile), nitrate of lime and calcium cyanamide, 25,169 t. The export included 129,102 t. of minoral superphosphates, and 234,385 t. of basic slag.

REPORT ON THE FINANCIAL AND ECONOMIC CONDITIONS IN URUGUAY, DATED SEPTEMBER, 1923. *By* A. E. CLEUGH, *H.M. Vice-Consul, Montevideo. Department of Overseas Trade. Pp.* 30. *H.M. Stationery Office,* 1924. *Price* 1s.

It is unfortunately not possible to record any improvement in the position of Uruguay since 1922 (*cf. Chem. and Ind.,* 1923, 1118). The bad financial condition of the country must be improved by the raising of loans, increase in taxation, and development of industries. The last-named object is difficult of realisation owing to Uruguay's lack of fuel and raw materials such as iron. The country is vitally dependent on the demand for meat in European markets and this shows signs of improving. Trade returns and Customs receipts show a gradual but consistent increase; there is no question of a "boom" in prospect, but even with depressed foreign exchanges traders will be dealing with stable conditions. The first six months of 1923 showed a decided improvement over the corresponding period in 1922; in the former, imports were valued at $19,844,861 and exports at $40,038,827, in the latter, imports, $25,018,276, exports, $57,661,425 (at par $1=51·1·16d.; June, 1923, 42¾d.). The figures for imports are for customs purposes; for actual values the figures should be multiplied by 1·9 approximately.

Of the imports the United Kingdom provided in the first six months of 1923 $6,116,356, the U.S.A. being next in importance with $5,121,724. The stocks which had accumulated are now becoming exhausted and the exchange, though adverse, is fairly stable, both helpful factors in the import trade. Items of imports in the first six months of 1923 included "anilines," 4800 tons; 293,500 gal. tinplate, 319,000 t.; malt, 123,000 t.; olive oil, 222,000 t.; coal, 292,000 t.; fuel oil, 6,417,000 t.; gasoline, 870,000 gal.; kerosene, 2,530,000 gal.; naphtha, 2,133,000 gal.

The principal exports were frozen meat, and the other products of the cattle rearing industry, such as hides, wool, etc. There are no manufacturing industries in the country, even for supplying the home market, though some minor ones might be established if the tariffs at present in force could be modified to help the importation of raw materials and machinery.

THE INSTITUTION OF STRUCTURAL ENGINEERS

The Institution of Structural Engineers is arranging to hold an International Cement Congress at the International Building Exhibition, Olympia, London, on Tuesday and Wednesday, April 22 and 23, 1924.

It is proposed that the following and probably other subjects shall be discussed during the course of the Congress:—

1. Ciment fondu in practice.
2. Surface dust on concrete floors in factories.
3. Cement in sea water.
4. Cement in concrete roads.
5. Preparations to withstand oil.
6. The influence of size and shape in compression test blocks.
7. Microscopy of cement.
8. Porosity of concrete blocks.
9. The use of sea water in mixing cement.

The papers in these subjects will be grouped and printed in advance so that when the Congress meets a group of papers may be taken as read and discussed without waste of time.

The hours of meeting of the Congress will be 11 to 1 and 3 to 5 on each day.

The Council of the Institution believes that this Congress will do much towards the solution of problems which confront chemists, engineers, manufacturers and others connected with the cement industry.

The Council of the Society of Chemical Industry has nominated Dr. Geoffrey Martin and Dr. David Prentice as its delegates to the Congress.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, JANUARY 4, 1924 No. 1

EDITORIAL

IN all ages and, doubtless, in all countries some day has been set apart for the celebration of a new year. The celebration is invariably a festival, a day of rejoicing, a time when we look back on happy hours and look forward to fresh periods of happiness. The young have few real anxieties or real troubles, but trifling disappointments affect them deeply, and they are easily distressed by insignificant or imaginary causes; so it happens that as we grow older we get happier, we outgrow the times when our lives are regulated and ordered by parents, schoolmasters and other educators of youth; hospitality is better to give than to receive, and those who entertain a party of young people experience a more lasting pleasure than their guests. Dear and desired come the blessed hours, bringing gifts to all and sundry; some receive an undue share of the good things of this world, but the others are as fortunate or perhaps more so. Those who seek much are in want of much; it is good when tho gods distribute their gifts with sparing hand. Philosophers have for many centuries advised us not to look too far ahead, to consider the present rather than the distant future. Did not one of them in his Rules against Low Spirits tell us to take short views of human life not further than dinner or tea? New Year's resolutions do not appeal to us. "You will live and enjoy yourself to-morrow! Perhaps you are too late to do it to-day; the wise did it yesterday."

* * *

Looking back during the last year of our Journal we have found many things to cheer and encourage us. Chemistry is fresh and vigorous; our leaders have made such progress in the science that they can spare much to bestow upon the solidest and sublimest points of controversy and new invention, as an old writer hath it; we feel ourselves not degenerated nor drooping to a fatal decay, but waxing young again, entering the glorious ways of truth and prosperous virtue, destined to become great and honourable in these latter ages. If any of our readers feel that the Journal should be better, they will find editorial sympathy; the better the articles are that are sent to us, the more pleased are our readers and ourselves; it is to you we appeal for any improvement, your literary destiny is in your own hands and you can make it as exalted as you desire, *nos te nos facimus*, you may say to yourselves. Voltaire wrote to some critic: "*Le Siècle de Louis XIV vous paraît écrit d'un style ridicule, à la bonne heure : vous écrivez bien mieux, et j'en suis fort aise.*" To our readers we may say as a New Year's Greeting: "This is your Journal, make it as good as possible, we on our side will be as helpful as we can."

* * *

We acknowledge very gladly the help we have received from the Federal Council for Pure and Applied Chemistry, the Association of British Chemical Manufacturers, the Chemical Society and the Institution of Chemical Engineers, who have all made official use of this Journal for publication. The two important meetings at Cambridge last June stand out as landmarks in the history of Chemical Societies; we have celebrated the hundredth anniversary of the alkali trade and the fiftieth anniversary of the founding of Messrs. Brunner Mond & Co.; we have recorded with deep regret the deaths of several prominent chemists who have taken a large part in building up our science, and we have witnessed and sometimes taken part in some controversial discussions which clarify the minds of the writers as well as the readers. The year 1923 has perhaps contributed more than any other year to the knowledge of atoms and molecules and their effect on one another. We are reaping the harvest sown by Ramsay, the Curies, Moseley, Soddy, Rutherford, Dauvillier, Perrin, Bohr, Lewis and Langmuir. Future generations will say of such men: "Their's was the giant race before the flood," and will envy us for living in such exciting times.

* * *

We are glad to publish a communication on the smoke problem. It is a perfect scandal that in this country and at this time there should be whole counties overhung by smoke and many score of towns whose ugliness is made worse by reason of soot and the other forms of dirt which result from our primitive methods of burning coal. We enjoy as all of us do, the open hearth and its cheerful aspect but in our own fireplaces we burn a fuel from which most of the volatile constituents have been removed and we get all the advantages of the open hearth and a smokeless fuel. If this practice became general we should find a notable improvement in the atmosphere of our great towns. We who understand, or are supposed to understand, the effects of combustion should set an example to our less enlightened brethren.
